4. Nature of motor involvement with child in any comfortable position:

a. Observed abnormal movements? Y N

If Yes, abnormal,

1) Short –jerky Y N

2) Slow, writhing? Y N

3) Tremor Y N

b. Passive muscle tone: (use codes below for question 4.b. 1-3)

1 = Normal	4 = Suspect Decreased
2 = Suspect Increased	5 = Definite Decreased
3 = Definite Increased	6 = Varying tone

1) Neck and Trunk ___

	Right	Left
2) Upper extremity muscle tone:	___	___
3) Lower extremity muscle tone:		
a. Hip and knees	___	___
b. Ankles	___	___

5. Is there scissoring of the legs on vertical suspension? Y N

6. Gross Motor Function Level: ___
(Use work sheet (NF05A) to determine level)

1 = Normal	4 = Level 2	7 = Level 5
2 = Possible Level 1	5 = Level 3	
3 = Level 1	6 = Level 4	

7. Hand preference ___

1 = None	3 = Exaggerated Left
2 = Exaggerated Right	

C. REFLEXES / MOTOR SKILLS / DIAGNOSES

1. Protective reactions (anterior, lateral and parachute) ___

1 = Symmetric 2 = Asymmetric 3 = Not present

2. Limb movements

1 = Symmetrical 2 = More on right 3 = More on left

a. Upper limbs ___

b. Lower limbs ___

For questions 3 – 5 use the following codes
1 = Normal (1 to 3+) 2 = Absent (0) 3 = Hyperactive (4 +)

	Right	Left
3. Deep tendon reflexes – upper extremities	___	___
4. Deep tendon reflexes – knees	___	___
5. Deep tendon reflexes – ankles	___	___
6. Ankle clonus	___	___

1 = None (≤ 4 beats)
2 = Present (> 4 beats)
3 = Sustained

7. Plantar reflexes ___ ___

1 = Flexor plantar response	3 = Spontaneous extension ± fanning
2 = Extensor plantar response	4 = Inconsistent results

8. Functional gross motor skills

a. Axis-head and neck: ___

1 = Normal head control
2 = Abnormal, but can hold head up for extended period (≥ 5 min.)
3 = Poor head control but can hold head up for short period
4 = No obvious head control

b. Axis-trunk: ___

1 = No apparent problem
2 = Can sit unsupported but less secure and stable than normal child of same age
3 = Cannot be left in sitting position unless self-supported
4 = Severe impairment: Difficult to place or maintain in sitting position

c. Lower limb function-gait: ___

1 = No significant problem with gait; walks fluently
2 = Gait functional but not fluent, no device required
3 = Gait functional, non-fluent and requires device
4 = No independent walking

d. Upper limb function: ___

1 = No apparent problem with bimanual tasks
2 = Some difficulty using both hands together
3 = No functional bimanual task

e. Hand function: 1) Right 2) Left ___ ___

Hi Marie
I had gotten these before. Can you please insert the relative risks as Abhik has asked for. Once we have final data lock, you will need to check that all the values and P values etc and stats are corrected.
Please see my comments to you in yellow. We need to correct the study number to 1317 and correct each group size.
I have not attached the Tables as you have them and I made no changes to them.
Thanks Marie
I want to get this paper out to the committee and then ready for submission
Neil

Abstract

Background: The most appropriate initial and ongoing respiratory support for the extremely low birthweight infant (ELBW) has not been established by adequate prospective evidence. The current usual approaches include the early use of continuous positive airway pressure (CPAP) or the early administration of surfactant following endotracheal intubation.

Methods: The SUPPORT study was a randomized multicenter 2 X 2 factorial trial that enrolled preterm infants of consenting parents of 24 0/7ths weeks to 27 6/7ths weeks by best obstetrical estimate within 2 prospective strata, 24 to 25 6/7ths weeks and 26 to 27 6/7th weeks. Infants were randomized to CPAP or surfactant; those randomized to CPAP had CPAP initiated in the delivery room and were subsequently treated using a permissive strategy allowing higher PaCO2s and extubation at higher ventilator settings and infants randomized to surfactant were intubated and received surfactant within 60 min minutes of birth. All infants were also randomized to one of 2 ranges of SpO2 while in the NICU and receiving supplemental oxygen, a low target range of 85% to 89% and a high target range of 91% to 95% using specifically altered blinded oximeters.

Results: The study enrolled 1317 infants from January 1 2004 to March 1 2009. There were 565 infants enrolled in the lower gestational age strata, and 751 in the higher strata. In the delivery room, 66% of the CPAP infants received positive pressure ventilation compared with 93% of the surfactant infants, and surfactant was given to 14% of the CPAP versus 51% of the surfactant group (all p<0.001), and 67% of the CPAP infants received surfactant at any time during their hospitalization,. The primary outcome of death or BPD, defined as the need for supplemental oxygen at 36 weeks post conceptional age was 48% versus 54%, ($p < 0.05$, Marie can you please provide the RR and CI when adjusted for gestational age, center and familial clustering). There was a significantly lower mortality in the 24 to 25 weeks strata for the infants in the Surfactant arm, (24% vs 32%, p=0.03). There were no differences overall for death in the delivery room nor any differences in length of stay, or days of oxygen for survivors, and the need for oxygen at discharge. More CPAP infants were alive and off mechanical ventilation by day 7, (p=0.015) and fewer required post natal steroids for BPD, (p<.0004). All infants in the Surfactant arm were intubated, compared with only 77% of the CPAP infants requiring intubation during their nursery course, (p<0.001). There were no differences between the groups for air leaks including pneumothoraces.

Conclusions: The use of early CPAP with a permissive ventilator strategy results in a decrease in death or BPD defined as the need for oxygen at 36 weeks post conceptional age compared with

Comment [AD1]: I would provide the relative risk and 95% CI instead of, or in addition to the p value. Same goes for other CPAP vs surfactant outcome comparisons, both here and in the main text.

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

the use of surfactant within 1 hour of birth and a conventional mechanical ventilation approach. There were no increased adverse outcomes in the CPAP group, and the surviving infants will be followed for a complete neurodevelopmental assessment at 18 to 22 months. Early CPAP and the use of a permissive ventilator strategy is an evidence based approach for the initial respiratory support of the ELBW infant.

Introduction:

At the present time, there is no agreement as to the optimal approach to respiratory support for the extremely low birth weight (ELBW) infant following delivery. Positive End Expiratory Pressure (PEEP) has been shown to be of benefit in maintaining functional residual capacity (FRC), and continuous positive airway pressure appears beneficial during cardiopulmonary resuscitation[1]. Gregory et al in 1971 first demonstrated that the use of CPAP started at approximately 5.9 hours (+12.4hrs) for their infants < 1500 gm at birth, improved oxygenation[2] in newborn infants with respiratory distress; these observations were followed by prospective studies that demonstrated improved survival in premature infants treated with early CPAP[3]. A review of prospective studies evaluating early (not delivery room) CPAP in the pre-surfactant, pre-antenatal steroid era found that early CPAP improved survival overall and for infants greater than 1500 gm, and was associated with increased pneumothoraces.[4] A more recent review of prophylactic CPAP started in the delivery room reviewed only 2 available trials and found no significant difference between the CPAP and conventionally managed infants and noted a trend to increased adverse outcomes for the CPAP treated infants.[5]

There is substantial retrospective evidence suggesting a benefit for early CPAP in experiences from both the US and other countries.[67] These reports have documented a decrease in the need for mechanical ventilation among very preterm infants without an increase in morbidity following the initiation of early CPAP treatment.[8910]

The current available evidence demonstrates that prophylactic and early surfactant treatment at less than 2 hours of life significantly decreases mortality, air leak, and BPD in preterm infants.[1112] Overall surfactant has not been reported to significantly reduce BPD, but may do so for the most immature infants and has not been found to significantly reduce subsequent neurodevelopmental impairment (NDI).[13]

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

The recent COIN trial randomized 610 infants from 25 weeks 0 days to 28 weeks 6 days gestational age at birth, who were able to breathe at 5 minutes of age and had evidence of respiratory distress at that time. Infants were randomized to either intubation and ventilation or CPAP at 8 cm H20. CPAP infants were intubated if they met failure criteria.[14] This study did not compare early CPAP to the early administration of surfactant, and surfactant use followed unit standard of care. There was a significant increase in the occurrence of pneumothoraces in the CPAP group (9.1% vs 3.0%, p=.001), most occurring within the first 2 days, consistent with the findings of an earlier meta analyses[46], and a reduction in death or the need for oxygen at 28 days in the CPAP infants (odds ratio, 0.63; 95% CI, 0.46 to 0.88; P=0.006) with no difference in death or BPD at 36 weeks.

Field Code Changed

Formatted: Font: 12 pt, Superscript

In view of the current interest in the use of early CPAP and the lack of prospective comparisons of this approach with the evidence based intervention of prophylactic or early surfactant, the SUPPORT study was designed to compare these approaches for the most preterm infants. We also randomized infants to 2 ranges of pulse oximetry targets during their exposure to oxygen using a factorial design, and the results for the oximetry study will be reported separately.

Methods

This was a randomized, factorial 2X2 design multi-center trial conducted by the NICHD Neonatal Research Network. This report describes the prospective comparison of CPAP and a permissive ventilatory strategy begun in the delivery room and continuing in the NICU with the early (< 1 hour) intratracheal administration of surfactant followed by conventional mechanical ventilation.

Infants were also randomized to a prospective comparison of a lower SpO2 range (85% to 89%) with a higher more conventional SpO2 range (91% to 95%) until the infant was no longer requiring ventilatory support or oxygen using purpose altered oximeters. These results will be separately reported.

The primary hypothesis of this trial was that relative to infants managed with prophylactic/early surfactant and conventional ventilation that the use of early CPAP and a permissive ventilatory strategy in infants of 24 to 28 weeks gestation with continuing CPAP in the NICU will result in an increased survival without BPD at 36 weeks.

Eligible infants were 24 0/7ths to 27 6/7th weeks at birth by best obstetrical estimate, born at a randomizing center, for which a decision had been made to provide full resuscitation, without known malformations, and for whom parental consent had been obtained. The infants were

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

randomized within each center to 2 gestational age strata, 24 0/7ths to 25 6/7ths weeks, and 26 0/7ths-27 6/7ths weeks.

CPAP Arm - Delivery room management: A T-piece resuscitator, a neonatal ventilator, or an equivalent CPAP methodology was used at all sites for the delivery room administration of CPAP. CPAP or ventilation with PEEP both at a recommended 5 cm H_2O was utilized if the infant required positive pressure during resuscitation. CPAP was continued until admission to the NICU using the T-piece resuscitator or equivalent device and a face mask or nasal prongs. CPAP infants were not to be intubated for surfactant only in the DR, and CPAP infants who required intubation for resuscitation were to receive surfactant within 60 minutes of birth. Intubation for these infants was performed only for the standard NRP indications including failure to respond to positive pressure ventilation (PPV) with evidence of continuing cyanosis or bradycardia, the need for chest compressions, the need to administer intratracheal medications, or other situations in which the resuscitation team determined that surfactant is urgently required.

NICU management: Intubation was performed at any time for the occurrence of repetitive apnea requiring bag and mask ventilation, clinical shock, sepsis, and/or the need for surgery. While intubation was never required by protocol, CPAP infants could be intubated if they met any of the following criteria: an FiO_2 >.50 required to maintain an indicated SpO2 $\geq$ 88% for one hour, an arterial $PaCO_2$ > 65 torr documented on a single blood gas, or hemodynamic instability defined as a low blood pressure for gestational age and/or poor perfusion, requiring volume and/or pressor support for a period of 4 hours or more. If intubated within the first 48 hours of life infants were to receive surfactant.

Extubation for CPAP infants was to be attempted within 24 hours if all of the following criteria were met: a PaCO2 < 65 torr with a pH > 7.20, an SpO2 > 88% with an FiO2 < 50%, a mean airway pressure (MAP) < 10 cm H2O, ventilator rate < 15 bpm, an amplitude < 2X MAP if on high frequency ventilation (HFV), and hemodynamically stable, and without a clinically significant patent ductus arteriosus. Re-intubation criteria were the same as those for intubation. After 3 intubations CPAP infants were treated using NICU standard of care.

Surfactant Arm: All infants were to be intubated within 1 hour of life and receive surfactant, followed by continued ventilation. All infants were to be extubated within 24 hours of meeting all of the following criteria: $PaCO_2$ < 50 torr and pH > 7.30 An FiO2 $\leq$ 35 with a SpO2 > 88%, a mean airway pressure (MAP) < 8 cm H_2O, ventilator rate $\leq$ 15 bpm, an amplitude < 2X MAP if on high frequency ventilation (HFV), and be hemodynamically stable with no evidence of clinically significant PDA. Once extubated Surfactant infants were treated using NICU standard of care.

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

These criteria were in effect for the first 14 days of life, following which the infant was treated as per NICU standard of care. For both arms of the trial intubation could be performed at any time for the occurrence of repetitive apnea requiring bag and mask ventilation, clinical shock, sepsis, and/or the need for surgery.

Randomization was stratified by center and gestational age group, utilizing specially prepared double-sealed envelopes. Deliveries were randomized as a unit, and thus multiples, were randomized to the same arm of the trial.

Hypothesis and sample size: We hypothesized that early CPAP would reduce the incidence of death or survival with BPD at 36 weeks, (using the NRN occurrence of death or survival with BPD of 67% using the year 2000 data), and the occurrence of death or survival with neurodevelopmental impairment (NDI) at 18 to 22 months (using the NRN occurrence of NDI of 61% using year 2000 data) by 10%. We increased the sample size by a factor of 1.12 to allow for multiples to be randomized to the same treatment as this introduced a clustering effect into the design, and increased the sample sizes by a further 17% to adjust for attrition after discharge and before follow-up. This resulted in a sample size of 1312 infants. This sample size was not large enough to determine, with sufficient power, an interaction effect between the 2 factorial arms.

In addition there was a prospective decision to also evaluate the occurrence of BPD using the Physiologic Definition which required an attempt at oxygen withdrawal for infants who required < 30% oxygen at 36 weeks and assigned a diagnosis of BPD to any infant who required more than 30% oxygen at 36 weeks or who required positive pressure support. [1516]

Statistical analyses: Intention-to-treat analyses were performed. The denominator used to calculate the rate of each outcome was the number of infants for whom that outcome was known. The primary analyses focused on the percent of each Group who developed their respective outcome measure of survival without BPD at 36 weeks. Adjustment was performed as pre-specified for gestational age, center and familial clustering using robust Poisson regression implemented in a Generalized Estimating Equation (GEE) model to obtain adjusted relative risks. A two-sided P value of less than 0.05 was considered statistically significant. An independent data safety monitoring committee reviewed the interim safety and efficacy results, including those concerning adverse outcomes, four times. Lan-DeMets spending functions with Pocock (O'Brien-Fleming) boundaries were used to develop stopping rules for interim safety and efficacy monitoring. Safety outcomes monitored included death, pneumothorax, intraventricular hemorrhage and a combination of any of the above events.

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

The study was approved by Human Subjects Committees at all participating sites and RTI, the NRN data center that managed and analyzed all the data, and parental consent for participation in the trial was required before delivery.

Results:

There were 1317 infants enrolled in this trial from Jan 1 2004 through to Mar 1 2009 . The trial was temporarily suspended by the DSMB because of concerns regarding the oximetry data in November 2005 but after a complete review the trial was continued in February 2006 with no protocol changes. The patient descriptive information for the CPAP versus Surfactant arms is shown in Table 1. There were 565 infants enrolled in the lower gestational age strata, and 751 in the higher strata. Marie can you correct these – we had one additional child and I do not know which arm that infant was in – the Tables need correcting for the actual number as well – they all total 1316 – and we have 1317 There were no significant differences for sex, birth weight, Apgar scores or race between the 2 treatment groups. The Surfactant group received significantly more epinephrine in the delivery room and had a trend for higher DR mortality which was not significant.

Formatted: Highlight
Formatted: Highlight
Formatted: Highlight
Formatted: Highlight

In the delivery room, 66% of the CPAP infants received positive pressure ventilation compared with 93% of the surfactant infants, and surfactant was given to 14% of the CPAP versus 51% of the surfactant group, and 67% of the CPAP infants received surfactant at any time during their hospitalization, (all $p<0.0001$). Intubation in the DR occurred in 34% of CPAP infants compared with 93% of surfactant infants, $p<0.0001$, Table 2.

The primary outcome of death or BPD, defined as the need for supplemental oxygen at 36 weeks post conceptional age was significantly lower for the CPAP group compared with the Surfactant group, 48% versus 54%, ($p < 0.05$, when adjusted for gestational age, center and familial clustering as prespecified Marie we need the RR etc as Abhik has asked for)). Death during the hospitalization was 4% lower for the CPAP group overall, and was significantly lower in the CPAP arm for the 24 to 25 week strata, Table 4. There was a non-significant reduction in the occurrence of BPD using the need for supplemental oxygen, 40% vs 44%, p=0.27. Using the Physiologic Definition for BPD there was no decrease in the occurrence of BPD in the CPAP group (40% vs 41%, p=0.96), and a non-significant reduction in the occurrence of death or Physiologic BPD at 36 weeks in the CPAP group, (48% vs 51%, p=0.32).

There were no differences overall for death in the delivery room nor any differences in length of stay, or days of oxygen for survivors, and the need for oxygen at discharge. (Table 3). More CPAP infants were alive and off mechanical ventilation by day 7, (p=0.01). There were no differences between the groups in air leaks in the first 14 days, air leaks during the hospital

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

stay, medical or surgical NEC, PDA requiring surgery, or severe IVH. All infants in the Surfactant arm were intubated, compared with 83% of the CPAP infants who required intubation during their nursery course, ($p<0.0001$). There was a significant reduction in the use of postnatal steroids for BPD in the CPAP infants compared with the Surfactant infants, 7% vs 13%, p=.0004).

Strata Results: 24 – 25 weeks Gestation

Comment [AD2]: Do we need to preface some justification for looking within strata?

There were significantly more non-Hispanic black infants in the CPAP group compared with the Surfactant group. The differences are shown in Table 4 (24-25 wk Strata). CPAP infants had a significantly lower mortality 24% vs 32%, p=0.~~03~~028. There was a significantly higher exposure to postnatal steroids for BPD, 21% vs 13%, p=0.02 for the Surfactant group, and there were more infants alive and off mechanical ventilation at 1 week in the CPAP infants in this strata.

26-27 weeks Gestation

There was no difference in mortality for the CPAP vs Surfactant groups, 10% vs 11%. The CPAP infants required fewer days of oxygen, 36.8 vs 46.5, $p<0.01$, lesser days of mechanical ventilation, 10.7 vs 14.2, $p<0.01$, and less postnatal steroids for BPD, 3% vs 8%, $p<0.01$.

Discussion:

The SUPPORT trial is the first multicenter trial to compare early CPAP with early surfactant given within an hour of life in ELBW infants. The current trial is the largest study reported to prospectively compare the use of early CPAP and early surfactant for the ELBW infant and the only study to include infants of 24 weeks gestation. In a preliminary study we found that 100% of infants of 23 weeks gestation required intubation in the DR, and thus decided that such infants would be unlikely to be successfully treated with CPAP alone following delivery.[17] Others have retrospectively reported that some of these infants can be successfully managed with early CPAP, but the majority of such infants require intubation.[18]

Our study differs from the recently reported COIN trial[1414] in that we randomized all eligible ELBW infants of consenting families irrespective of whether they demonstrated spontaneous breathing, included infants of 24 weeks gestation and compared the CPAP/permissively ventilated infants with infants who all received surfactant within 1 hour of birth. Our method of using early CPAP and a permissive ventilation strategy was a result of previous retrospective reviews of practice which demonstrated that the unit with the most success using CPAP also utilized a very permissive approach for intubation and the initiation of mechanical ventilation. **Error! Bookmark not defined.**[8] We believed that testing this complete approach would provide a more relevant result as most units currently using early CPAP also tend to be permissive in their use of intubation.

Field Code Changed

Formatted: Font: 12 pt, Superscript

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

Our study has demonstrated that early CPAP and a permissive ventilator strategy when compared with surfactant given within 1 hour of birth is associated with a significant reduction in death or survival with BPD as defined by the need for oxygen at 36 weeks from 54% to 48%. We also noted a very significant 8% reduction in death in our 24 to 25 week strata, resulting in a number needed to treat of 12.5 for each additional survivor. The group of 565 infants in our 24 to 25 week strata to our knowledge represents the largest prospective group of such immature infants to be randomized in any neonatal trial evaluating respiratory interventions. We believe that this lower incidence of death in these infants along with a reduction of BPD and decreased durations of ventilation and exposure to post natal steroids in the overall CPAP group represents a substantial clinical benefit compared with the initial use of early surfactant.

Our rates of BPD are higher than those reported for the COIN trial, 33.9% vs 38.9%, but the difference between the arms is very similar. The higher rates seen in our study no doubt reflect the inclusion of infants of 24 weeks gestation and the lack of inclusion of infants greater than 27 6/7ths weeks, as well as the requirement in the COIN trial that the infants demonstrate adequate spontaneous breathing at 5 minutes of life.

We prospectively identified a number of safety outcomes that we chose to follow as investigators. These included the need for compressions in the delivery room, the occurrence of severe IVH, and the incidence of airleaks, initially defined as pneumothoraces but later altered to include pulmonary interstitial emphysema, pneumomediastinum and pneumopericardium. We did not find an increase in airleaks with the use of early CPAP at 5 cm H2O compared to the use of early surfactant.

The SUPPORT study was designed as a factorial design with each infant randomly receiving 2 interventions, CPAP vs Surfactant, and a lower versus higher SpO2 target range. While the study was not powered to detect an interaction between the 2 interventions, we did prospectively agree to evaluate such interactions and none were found. Both arms of the study were adequately powered for both the outcomes at neonatal discharge and the occurrence of survival NDI at 18 to 22 months and these results will be presented after all survivors have been assessed.

Conclusions:

ELBW infants between 24 and 27 6/7ths weeks gestation at birth treated with CPAP and a permissive ventilator strategy compared with the use of surfactant within 1 hour of birth and conventional mechanical ventilation have a decreased incidence of death or survival with BPD based on the need for oxygen at 36 weeks PCA with no demonstrable increase in any adverse neonatal outcomes. Early CPAP with a permissive ventilator strategy is associated with a significant reduction in mortality in the most immature infants. Surviving infants will have a

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

complete neurodevelopmental evaluation at 18 to 22 months and these results will be separately reported.

Meg
We are so sorry for the confusion. You are correct that subjects (b) (6) and (b) (6) are NOT consented for the MRI secondary study. Please destroy the discs that were sent.

For subject (b) (6) this subject was consented for the MRI study and I have entered the MRI01 into the DMS and transmitted it as well. This subject had 2 head US that were both normal. The second was not done in window and there was no MRI done.

Thank you for your continued oversight and work on this study!

Gloria and Kim,

In a recent shipment of images you sent me images for:

(b) (6)
[redacted]
[redacted]

According to the data these kids are NOT enrolled in the MRI secondary. Both (b) (6) and (b) (6) do NOT have MRI01 forms. (b) (6) does have an MRI01 form, but it is indicated that this kid was NOT enrolled because you were not able to contact the family.

Are these kids enrolled into the study? If so, the MRI01 forms need to be entered and corrected. If they are NOT enrolled in the study, please let me know. I am attending the last reading later this week and do not want to read any images that I don't have to.

Please get back to me as soon as you can.

Thanks Marie
For now we will report BPD using oxygen to include only infants on oxygen.
Later in a subsequent paper we can use the CPAP/Vent +RA infants. For this
the queries will be useful as I have already seen some for which the infant
was Post-op for eye surgery - this would not be BPD
The only possible adjucation for BPD would be whether others want to look at
the physiologic definition infants - there the results were not close to significant so I don't see how that would change things but lets get all the
final queries. Once you have those lets finalize the BPD numbers and stats.
Whenever you can finalize the Consent paper please send to Rose as she needs
to get Approval to submit
Thanks
Neil

Hi Marie
A couple of queries
Where are we with Wades consent paper? - Does it require more input from you? I think that this paper is ready for submission if you are done with it.
What is the status of the SUPPORT data regarding the final queries and edits for the stats?
Will you be able to put the final values and stats in the paper in time to send the Surf-CPAP paper out for the Subcommittee meeting. I realize that ROP data may be more complex, but I would like an update so that I can prepare for the meeting.
Thanks
Neil

Hi Jamie and Rose

Thanks - these look great.

It may be helpful to send an email out again to the site - or even add the information to the technical memo - about when the tracking form is "delinquent". I believe the coordinators are very concerned on that point.

Thanks again for all your hard work!

Susan

> Rose, Susan, and Kristi,
>
> Attached is the technical memo I have drafted that spells out tracking for the SUPPORT MRI School Age Follow-up. I have placed the information that I have been emailing in the attached technical memo. Because the Object Permanence Ancillary Form (MRI09A) was released at about the same time, questions about that secondary go hand in hand with the SUPPORT MRI School Age Follow-up tracking at 3-4 years. So, I have also drafted a memo that spells out exactly which pts should have the MRI09A form completed. Again, this memo includes information that I have been sending in emails.

Subject: FW: NICHD NRN SUPPORT TRIAL ROP data adjudication conference call

Hi Rose,
I have concerns.

You only have one ophthalmologist. David Wallace can not be the only person in the group that has the clinical experience to make these judgements.
A phone call is a very inefficient use of time for these judgments . Especially with that many people, I don't think it will work well.
But maybe this is just a planning session?

David has identified 5 other ophthalmologists form our NRN centers that he thinks would be good. I will include his list. I have a partial draft letter, not sent, for them [attached] because I was waiting to talk to Abhik and Rose and Kris about how we would do this. Maybe you have decided already ???
Sharon Freedman here at Duke is excellent, and she knows plus disease. Which centers are in

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

the Network?
David

Dale, From the list, I recommend 4 others (should make 6 if all agree):
Hutchinson
Hoffman
Neely
Yang
David

The Adjudication committee can not make a judgment about the primary outcome.
We have not established what the process will be, and that should be done before cases are examined.
I can help you a lot with how to present the data to the adjudication committee so that they can most efficiently absorb it.

Dale

Subject: NICHD NRN SUPPORT TRIAL ROP data adjudication conference call

Dear all,

We will have the NICHD NRN SUPPORT Trial data lock on 10/20/09 and would like to ask that you be part of an adjudication committee to determine acute final ROP status (if possible) for cases that are not straight forward. We would like to have this conference call on **Friday, October 23, 2009 from 3:00 = 5:00PM (EST).** We would be sending the data for case reviews on 10/22/09. Currently, there are about 50 cases where the infant had one exam in zone 3 (instead of the two consecutive exams required to meet our final status requirement) and about 50 who only had exams in zone 2. The study subcommittee may determine these later cases are classified as undetermined per the study manual definition but after data lock we will have a better idea of cases needing review. I have attached the study manual for reference.

Please let me know if you are willing and available this date and time.
Thanks,
Kris

Rose, Susan, and Kristi,
Attached is the technical memo I have drafted that spells out tracking for the SUPPORT MRI School Age Follow-up. I have placed the information that I have been emailing in the attached technical memo. Because the Object Permanence Ancillary Form (MRI09A) was released at about the same time, questions about that secondary go hand in hand with the SUPPORT MRI School Age Follow-up tracking at 3-4 years. So, I have also drafted a memo that spells out exactly which pts should have the MRI09A form completed. Again, this memo includes information that I have been sending in emails.

I'd like to distribute these memos at the same time and will post them to the website where their respective forms and protocols are located. In the meantime, please let me know if you have any changes.

Thanks, Jamie

Subject: RE: school age follow up - information on tracking

Below are the emails that I have recently sent concerning tracking for the SUPPORT MRI School Age Follow-up. I will draft a technical memo outlining this information (to be posted on the website) to avoid further confusion. Thanks for letting us know that it is a point of confusion.
Jamie

RTI INTERNATIONAL | **Memorandum**

Date: October 20, 2009

To: NICU PIs, Coordinators, Follow Up PIs, Follow-up Coordinators participating in the SUPPORT Neuroimaging and Neurodevelopmental Outcomes secondary study

From: Data Coordinating Center

Re: Object Permanence Ancillary Form (MRI09A)

The MRI09A Form (version dated 1/6/09 distributed January 12, 2009) is the Object Permanence Ancillary Form. It should be completed only for babies enrolled in the SUPPORT Neuroimaging and Neurodevelopmental Outcomes secondary study that are seen at 18 months and have a Bayley III exam.

The MRI09A form is used to record three additional items from the Bayley III exam administered at the 18 month follow-up visit. These three additional Bayley III items (40, 45, 50) will be recorded to assess early working memory by evaluating object permanence. As was stated in the protocol, patients not yet seen for the 18 month follow-up visit will have these three additional items recorded prospectively. There were approximately 70 patients from this study who had already been seen for the 18 month follow-up visit when the MRI09A form was released. The three items for these patients will be collected by NRN Center staff from the Bayley III score sheets, if retained.

The MRI09A form is located on the NRN website:
Protocols – SUPPORT – Secondary Studies – Object Permanence Ancillary – Forms – MRI09A

RTI has been posting Object Permanence Ancillary Pending Reports since March 2009 on the private gateway of the NRN website with the other site-specific reports under: Administration – Site Reports – [Click on Your Center] – Object Permanence Ancillary (MRI09A) Pending Report.

Patients are included on this pending report if they participated in the Neuroimaging and Neurodevelopmental Secondary to SUPPORT and have already been followed at 18 months (and had a Bayley exam). Patients with windows yet to open are also included in this report. Once the MRI09A form has been keyed, patients will no longer appear on the pending report.

Please submit any questions to Jamie Newman at newman@rti.org.

Note: The Object Permanence Ancillary Study protocol and MRI09A form are posted to the private gateway of the NRN website under this location:
Protocols – SUPPORT – Secondary Studies – Object Permanence Ancillary - Protocol
Protocols – SUPPORT – Secondary Studies – Object Permanence Ancillary - Forms – MRI09A

Re: Tracking for SUPPORT MRI School Age Follow-up Patients

The SEF01 Form (version dated 1/7/09 distributed January 8, 2009) is the 3-4 Year Status Form for the SUPPORT MRI School Age Follow-up Study. This form should be completed only for patients enrolled in the SUPPORT Neuroimaging and Neurodevelopmental Outcomes study with a successful MRI who were discharged from the hospital alive.

The SEF01 form is located on the NRN website:
Protocols – SUPPORT – Secondary Studies – MRI School Age Follow-up - Forms – SEF01

Tracking tools were added to Centers' Network computers in early January 2009 which list which patients should have the SEF01 form completed. Once coordinators have contacted the SUPPORT families involved in the Neuroimaging and Neurodevelopmental Outcomes study at 3-4 years of age, they are asked to key the SEF01 Form so that the 3-4 year status will show up in the tracking reports. Following are instructions for using these tracking tools that were distributed when the reports were added to the Network computers:

Upon opening the Support DMS, select the "Reports" button. At the bottom of the report list you have the option to select either "6.5-7.5 Yr Follow-up Tracking List" or "6.5 to 7.5 Yr Follow-up Patient Contacts".

6.5-7.5 Yr Follow-up Tracking List:
This is a listing of all patients randomized into Support with a successful MRI. It provides the user with necessary 6.5 to 7.5 year follow-up dates and lists the patients' status at various protocol data points. There are three display options for the listing, these are as follows.

View Report: The report will open in MS Access so the user can view the complete listing of patients randomized into Support with an MRI.

Print Report: The report will print to the user's default printer.

Export to Word or Excel: A window will appear asking the user if they want to export the listing. Upon clicking "Yes", the user will be asked to provide the directory path where they want the document to be saved (the default location is c:\network\nicu\followup - this can be changed to any valid directory on the computer). Next the file name will be requested (the default name is Supp6to7_YYYYMMDD.xls – 'YYYY' being the four digit year, 'MM' being a two digit month and 'DD' being a two digit day. This can be changed as well). Click OK and the spreadsheet will be saved. The Excel document does NOT automatically open up after it is exported.

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

6.5 to 7.5 Yr Follow-up Patient Contacts:

This is a follow-up tool which is a full-page document for each patient. It provides the user with the patient ID, needed dates and space to hand write the patient's contact information. There are two display options for this tool, these are as follows.

View Report or Print Report: A window will open listing all the randomized Support patients with an MRI (user must scroll down to see all the IDs). The user will click on the check box next to the patient ID for which they want the tool created. They then will click on the "View Tool" or "Print Tool" button. "View Tool" opens the document for viewing. The "Print Tool" prints the document directly on the user's default printer. To go back to the previous screen the user will click "Return".

Export to Word or Excel: The user will click on the check box next to the patient ID for which they want to export a document to Word. They will then click on the "Export to Word" button. A window will appear asking the user if they want to export the listing. Upon clicking "Yes", the user will be asked to provide the directory path where they want the document to be saved (the default location is c:\network\nicu\followup - this can be changed to any valid directory on the computer). Next the file name will be requested (the default name is ContactList_YYYYMMDD.rtf – 'YYYY' being the four digit year, 'MM' being a two digit month and 'DD' being a two digit day. This can be changed as well). Click OK and the document will be saved. The Word document does NOT automatically open up after it is exported. To go back to the previous screen the user will click "Return".

Please submit any questions to Jamie Newman at newman@rti.org.

Note: The SUPPORT MRI School Age Study protocol and SEF01 form are posted to the private website under this location:

Protocols – SUPPORT – Secondary Studies – MRI School Age Follow-up - Protocol
Protocols – SUPPORT – Secondary Studies – MRI School Age Follow-up - Forms – SEF01

Date: Tuesday, October 20, 2009 12:41:28 PM

Hi all,

Please note that what I just sent out was a sample of 3 infants so that Dale could look at the information being included in the report and make any changes that are necessary. I will send out the actual report for the adjudication committee as soon as data transmitted to RTI today have been processed.

Thanks,
Marie

Subject: FW: adjudication

We will need an adjudication. We should have 3 ophthalmologists who are unaware of any study results look at the exams with indeterminate outcomes. We will need a table for each child constructed as follows:

Post menstrual age at exam (weeks)	Chronologic age at exam (in weeks)	Next several columns – data from SUPP10 for each exam				

For each infant, we will need birth weight and gestational age at birth – data must be de-identified (no dates).

I will look over the list that David Wallace sent and select folks for you to contact by the end of the day
Dale – do I have the necessary items in the table?

Subject: RE: adjudication

I think it is worth the effort to do the adjudication. The results will be:
some who did have an adverse primary study outcome
many who had a good long term outcome, but we'll never know if they actually met criteria and resolved spontaneously
several that we'll be able to say almost certainly never met the criteria for the primary outcome data.

Given those three categories, it is very helpful to look at the primary outcome data and ask:
IF WE ASSUME
the probably bad were bad (first category)
and the probably good were good (last category)
and list a missing the middle category..... what does that do to the analysis?
the usual conclusion is 'no effect on conclusions'
this is very reassuring
it is reasonably conservative ... but ask Das and Wallace

IF further want to add in the 'middle category' in some fashion, I'd say worst case scenario, assume half good and half not... what does that do?

....
So if I'm a reviewer, I want to know that you examined the impact of these unknowns on your primary outcome. I don't want you to change your primary outcome, but I want you to do the work to tell me what the impact of those missed kids could have been. Would they have potentially changed your conclusions?
Usually when you do this you find that the answer is "No". (when there is pretty good follow up)

when the answer is squishy, it is usually because the follow up rates are quite bit lower, like 70-80%

Richard
This paper provides a nice analysis to promote the use of early nutrition, particulalry enteral nutrition to enhance outcomes.

Specific comments-
My version is misisng an abstract and table 2.
The abstract should impress the point that nec rates are unaffected.

Thanks for putting this together!
Rose

Rose

On spreadsheet of abstract noted that Piazza secondary analysis of SUPPORT data was rejected. I thought this was put on hold pending analysis of primary data rather than rejected? If I am correct, can it be revised before spreadsheet is distributed at the Steering Comm meeting

SUPPORT ROP Queries for Center 3-Case Western University

Center ID number=3=Case Western University Network number=(b) (6)

Query 1	Query resolution: Center notes
On SUPP10 exam dated (b) (6) right eye meets criteria for Threshold ROP per MOP but Threshold not ='Y' on form.	Changed right eye threshold='Y' per MOP.

Center ID number=3=Case Western University Network number=(b) (6)

Query 1	Query 2	Query resolution: Center notes
On SUPP10 exam dated (b) (6) left eye meets criteria for Threshold ROP per MOP but Threshold not ='Y' on form.	On SUPP10 exam dated (b) (6) right eye meets criteria for Threshold ROP per MOP but Threshold not ='Y' on form.	Error. Changed threshold='Y' per MOP on form for both eyes.

Center ID number=3=Case Western University Network number=(b) (6)

Query 1	Query resolution: Center notes
On SUPP10 exam dated (b) (6) lowest zone is '5=Post laser/cryo' but highest stage is not '6=Post laser/cryo.'	Error. Highest stage should be 6=Post laser/cryo. Corrected.

Center ID number=3=Case Western University Network number=(b) (6)

Query 1	Query resolution: Center notes
Per SUPP10 surgery for ROP was performed in only one eye. If this is correct, please F5 to confirm.	Error. Should be laser surgery for both eyes. Corrected.

Center ID number=3=Case Western University Network number=(b) (6)

Query 1	Query resolution: Center notes
Per SUPP10 infant had stage 4 or 5 ROP without a previous exam showing threshold ROP. If this is correct, please F5 to confirm.	Error. Both eyes are mature (zone=4). Corrected.

Center ID number=3=Case Western University Network number=(b) (6)

Query 1	Query resolution: Center notes
Per NG03 ROP was diagnosed but ROP is not entered on SUPP10 exams.	Error. ROP on NGO3 should be **'No'**. Corrected

Center ID number=3=Case Western University Network number=(b) (6)

Query 1	Query resolution: Center notes
On SUPP10 exam dated (b) (6) left eye meets criteria for Threshold ROP per MOP but Threshold not ='Y' on form.	Error. Changed threshold='Y' per MOP. Corrected.

Center ID number=3=Case Western University Network number=(b) (6)

Query 1	Query 2	Query 3	Query resolution: Center notes
On SUPP10 exam dated (b) (6) left eye meets criteria for Threshold ROP per MOP but Threshold not ='Y' on form.	On SUPP10 exam dated (b) (6) right eye meets criteria for Threshold ROP per MOP but Threshold not ='Y' on form.	Per SUPP10 surgery for ROP was performed in only one eye. If this is correct, please F5 to confirm.	**Query 1/Query 2**-Eye exams on (b) (6) - changed threshold value per MOP (i.e. not using ophthalmologists remarks). **Query 3**-correct as recorded. Surgery only right eye.

Dear all,

Attached please find the final Support primary outcomes verification report. Please verify that the data for each case is correct by initially next to the data in the provided column. Please note there is only one field for initials per ID (in the ROP report); by initially her it means you have verified both the BPD and ROP data against the medical records. Please scan the completed report and send it to Dr. Higgins (please copy me for our records).

In addition, if you have not already received them, Dr. Higgins will be sending ROP, BPD and cross-form queries which require your immediate attention. Please note that we have added gestational age to the BPD queries; there are several infants who have different GA data for Support which do not match the NG02. Please verify the GA of these infants.

Thanks
Kris

Subject: RE: Duke report
Date: Monday, October 19, 2009 12:22:34 PM

Just to clarify, the BPD query responses which we previously received from Duke noted gestational ages that differed from what is entered on the NG02. This resulted in different dates for 36 weeks PMA being calculated by the center and by RTI. In the latest queries from Friday we have included the GA as it is entered on the NG02 so that you can check it against your records. Thanks very much for your help resolving these queries. If you have specific questions about the queries please contact me.

Thanks,
Marie

Subject: FW: Duke report

Dear all,

Attached please find the final Support primary outcomes verification report. Please verify that the data for each case is correct by initially next to the data in the provided column. Please note there is only one field for initials per ID (in the ROP report); by initially her it means you have verified both the BPD and ROP data against the medical records. Please scan the completed report and send it to Dr. Higgins (please copy me for our records).

In addition, if you have not already received them, Dr. Higgins will be sending ROP, BPD and cross-form queries which require your immediate attention. Please note that we have added gestational age to the BPD queries; there are several infants who have different GA data for Support which do not match the NG02. Please verify the GA of these infants.

Thanks
Kris

Marie
I finally got the SuUPPORT reminder out (via dial up- something is wrong with my computer)

I somehow lost the email with the Duke BPD missing queries- can you resend??
Thanks
Rose

Attachments: ROP queries 16OCT09.zip
BPD queries 16OCT09.zip
Cross-form queries 16OCT09.zip

Rose,

Attached are zipped files with queries for BPD, ROP and the cross-form checks. I've tweaked the queries slightly, so there may be some new ones. Thanks, as always, for sending them out.

Marie

Rose,
We have attached our responses to the queries. We have our computer back and we are in the process of entering all data and will transmit today.

I think we have exhaused all efforts. We will continue to look for these children and hopefully find for follow-up. See below:
Ellen

Department of Pediatrics - Division of Neonatology
Office: 404-778-1679
Fax: 404-778-1467

Hi,

Attached are ROP and BPD queries. We are missing ROP outcomes for a total of 97 infants who have not died and who have not been withdrawn from the study. Many of these are previously "excused," but we still have no firm ROP outcome on these infants. If you have any way of determining ROP outcome, please let us know. The data base will be LOCKED following data entry on OCTOBER 20, 2009.

Please attend to these asap. Thanks for all the effort!!!
Rose

Subject: RE: SUPPORT DATA LOCK DATE - OCTOBER 20

We queried centers that had infants withdrawn from the study to find out whether we could use their data, but I do not see a response from Emory. Apparently, some centers can still use the GDB data even if SUPPORT data were not collected after withdrawal. We need to know from the center what we are allowed to use per their IRB and consent for GDB vs. SUPPORT.

Dr Higgins and Kris
I have not as yet sent out the packet of information but plan on sending it out no later than tomorrow morning. I will provide the tracking information to both of you. Should I make 2 copies and send a package to both of you or where should I sent it?

Thanks
Kim

Kim
I did not receive anything from FED EX. Do you have a tracking number?

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

Also, we need a response to the following items by Monday:

Action items requiring a response to NICHD by October 19, 2009:

1. The collection of research data at DRH needs to be addressed and resolved so that source document can be obtained on infants in observational studies and trials to have complete data in the DMS.
2. A written plan for the process and resolution of edits and queries needs to be formulated and instituted at the Duke site detailing responsibility for staff completing the entry to RTI. This must be sent to NICHD.

a. All SUPPORT missing forms, batch edits, queries and action items listed below must be resolved immediately.

3. Duke is required to have all SUPPORT study primary outcomes for all 64 cases verified and the Primary Outcomes Report signed by Dr. Goldberg and/or Dr. Cotten to ensure the integrity of the data.

a. In addition, it is imperative that all data and neuro-images be sent to RTI immediately for the Support Neurodevelopmental Secondary Study. There are currently 2 infants with missing MRI images (b) (6))

4. A Weekly meeting for the NRN research staff (PI, alternate PI, Follow Up PI, clinical research director, research coordinator, research staff and data entry staff) is recommended to facilitate communication, resolution of current outstanding data, and ongoing protocol updates as well as other items relevant to NRN research.
5. The establishment of a communication plan for the Rochester site conducting the SUPPORT Secondary Breathing Outcomes interviews is requested. Ms. Zaterka-Baxter will Assist Dr. Fisher and send the necessary information to establish this process. The Breathing Outcomes FU windows for all patients are posted to the private NRN gateway.

Thanks
Rose

Cc: Das, Abhik; Zaterka-Baxter, Kristin
Subject: RE: SUPPORT DATA LOCK DATE - OCTOBER 20

We queried centers that had infants withdrawn from the study to find out whether we could use their data. We do not see a response from Emory. Apparently, some centers can still use the GDB data even if SUPPORT data were not collected after withdrawal. We need to know from the center what we are allowed to use per their IRB and consent for GDB vs. SUPPORT.

Attachments: SUPPORT infants missing ROP - Center 9 02OCT09.rtf

---

This infant was withdrawn on DOL 11, so we have no eye exams entered on the SUPP10 and the ROP outcome is missing. Missing outcome reminders have not been generated for the infant because of the withdrawal, but they were on the comprehensive list of infants with missing ROP that went out two weeks ago (see attached).

Subject: RE: NICHD NRN SUPPORT TRIAL ROP Adjudication Process conference call
Date: Wednesday, October 14, 2009 11:39:05 AM

Dear all,

We have scheduled a conference call for **Friday, October 23, 2009 from 4:00 = 5:00PM (EST)** to discuss a process to adjudicate cases with unclear ROP outcome. Contacts below:

Call in number: 1-866-675-(b) (6)
Pass code (b) (6) (the "#" sign at the end is required)

Thanks,
Kris

Subject: NICHD NRN SUPPORT TRIAL ROP data adjudication conference call

Dear all,

We will have the NICHD NRN SUPPORT Trial data lock on 10/20/09 and would like to ask that you be part of an adjudication committee to determine acute final ROP status (if possible) for cases that are not straight forward. We would like to have this conference call on **Friday, October 23, 2009 from 3:00 = 5:00PM (EST).** We would be sending the data for case reviews on 10/22/09. Currently, there are about 50 cases where the infant had one exam in zone 3 (instead of the two consecutive exams required to meet our final status requirement) and about 50 who only had exams in zone 2. The study subcommittee may determine these later cases are classified as undetermined per the study manual definition but after data lock we will have a better idea of cases needing review. I have attached the study manual for reference.

Please let me know if you are willing and available this date and time.
Thanks,
Kris

To: Das, Abhik; Zaterka-Baxter, Kristin; Gantz, Marie; 'Phelps, Dale'
Subject: FW: adjudication

We will need an adjudication. We should have 3 ophthalmologists who are unaware of any study results look at the exams with indeterminate outcomes. We will need a table for each child constructed as follows:

Post menstrual age at exam (weeks)	Chronologic age at exam (in weeks)	Next several columns – data from SUPP10 for each exam				

For each infant, we will need birth weight and gestational age at birth – data must be de-identified (no dates).

I will look over the list that David Wallace sent and select folks for you to contact by the end of the day
Dale – do I have the necessary items in the table?

Subject: RE: adjudication

If this were Inositol, I would yes absolutely yes.

Because SUPPORT is more complex I'm not so sure (with the 2x2 design, four outcome cells for analyses, 2 different primary outcomes).
However, I would favor having it in there. It relieves some uncertainties.

Dale

Sent: Tuesday, October 13, 2009 4:28 PM
To: Higgins, Rosemary (NIH/NICHD) [E]; Abhik Das
Cc: Zaterka-Baxter, Kristin
Subject: RE: adjudication

I think it is worth the effort to do the adjudication. The results will be:
some who did have an adverse primary study outcome
many who had a good long term outcome, but we'll never know if they actually met criteria and resolved spontaneously
several that we'll be able to say almost certainly never met the criteria for the primary outcome data.

Given those three categories, it is very helpful to look at the primary outcome data and ask:
IF WE ASSUME
the probably bad were bad (first category)
and the probably good were good (last category)
and list a missing the middle category..... what does that do to the analysis?
the usual conclusion is 'no effect on conclusions'
this is very reassuring
it is reasonably conservative ... but ask Das and Wallace

IF further want to add in the 'middle category' in some fashion, I'd say worst case scenario, assume half good and half not... what does that do?

....
So if I'm a reviewer, I want to know that you examined the impact of these unknowns on your primary outcome. I don't want you to change your primary outcome, but I want you to do the work to tell me what the impact of those missed kids could have been. Would they have potentially changed your conclusions?
Usually when you do this you find that the answer is "No". (when there is pretty good follow up)

when the answer is squishy, it is usually because the follow up rates are quite bit lower, like 70-80%

Dale
I have a practical pragmatic question –if the likely results for the adjudication are "unable to determine," is there a reason to expend the effort?

Thanks

Subject: RE: Finer SUPPORT Authorship ranking calculator (4).xls
Date: Tuesday, October 13, 2009 3:45:55 PM

Rose and all:

I have serious concerns about the importance of the % eligible as that metric provides little contribution to a trial. This is obvious from the results of this ranking. Some centers with minimal contribution rank higher that other that contributed more.

The carrot has to be given for the best reasons.

Subject: Finer SUPPORT Authorship ranking calculator (4).xls

Hi,
Stephanie generated the author order list as per the NRN policy for ranking. 50% weight is given to absolute number recruited into a trial and 50% weight is given to % enrolled/% eligible. This may be viewed as "not fair." I brought it up on the hypothermia aEEG call today (same type of scenario with Dallas recruiting a large number of patients).

I want to discuss at the SC meeting - perhaps this should be revisited.

Hi Rose-

Marie had a chance to review these and wanted to run these by you before we posted.

Carolyn

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

SUPPORT Subcommittee Call:
October 7, 2009

Participants: Drs. Finer, Carlo, Schibler, Higgins, Gantz, Laptook ,Das, Wallace. Ms. Zaterka-Baxter, Irene, Huitema, Newman.

Dr. Hintz's final protocol *Extended Follow-up at School Age (6½ to 7½ years) for the SUPPORT Neuroimaging and Neurodevelopmental Outcomes Cohort* was distributed to the subcommittee.

Support data lock is scheduled after the October 20th download. Dr. Gantz will continue to send Dr. Higgins weekly missing data reports to follow up with the sites.

SUPPORT Outcomes:

- The draft of the primary manuscript was sent to the subcommittee for review; BPD queries are still pending
  - The analysis of the CPAP vs. surfactant arm with pre-specified adjustments (GA, centers, multiples), showed no significant difference in the outcome of death or BPD by the physiologic definition. The outcome of death or BPD by oxygen at 36 wks was significant with a p-value just under .05 and favored CPAP.
  - In the small strata (24-25 wks), there was a significant increase in death in the surfactant arm (8%). However, overall there was no significant difference in death.
- The paper will be submitted to the NEJM

Comments:

- The traditional BPD definition is oxygen @ 36 weeks, however, 18 patients were on room air by CPAP or ventilation. The question is how to consider these patients with respect to BPD?
  - The 18 cases have not been evaluated in alternate analyses because Dr. Gantz did not want the outcome to influence alternate decisions.
  - Dr. Finer felt that the manuscript should report outcomes that are similar to other studies (e.g. COIN Trial) and to adhere to the definition of oxygen @ 36 weeks.
  - It is possible that these infants were on support in room air because of surgery.
  - There are only 3 cases where a baby was on CPAP or vent for a procedure and therefore not challenged.
  - The suggestion was to use a severity of BPD in Dr. Steven's Breathing Outcomes paper.

Pulse Oximetry

- Drs. Finer, Carlo, Das, Gantz and Wade Rich reviewed the pulse oximetry data together and found there was a significant increase in mortality in the low SpO2 arm by 4%. The low SpO2 arm had significantly less BPD by the definition of oxygen at 36 weeks (8% difference).
- The DSMC was tracking adverse events, including death, but the difference in death had not reached predefined significance levels for interim monitoring and no recommendations had been made.
- SUPPORT was the first trial to randomize infants to low and high arm of SpO2. There were no strong data in the literature prior to this study.
- Dr. Finer would like to get this manuscript published as soon as possible, to inform the community of the increase of deaths in the lower oxygen arm, including other studies currently randomizing infants to low SpO2 ranges. Suggest reporting ROP outcomes at Follow Up since there are currently several missing final ROP status data. The ROP data will not change the data related to death.

ROP

- The greatest difficulty is interpreting the ROP outcome due to missing final ROP status data.
  - About 50 patients had one exam in zone 3 but had not had a second consecutive exam with vessels in zone 3 and thus have not met the study criteria for final ROP status.

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

- The ROP data is quite problematic. Dr. Finer suggested an ROP adjudication process. However, after consulting with Dr. Phelps it is highly unlikely that the data will be reclassified.
- Another issue is classifying those who have pending ROP exams but die after discharge. Dr. Finer stated that the outcome is defined as ROP or death before discharge. If the patient did not have ROP (did not reach threshold or have surgery) and did not die before discharge, that the patient will not be coded for either.
- Currently at 38 have FU window closed and no ROP outcome. Over 600 have been seen already.
- As seen in the data you could have Stage 2 ROP in zone 2 and end up with mature eyes; could also have threshold, no surgery and regressing eyes. Low sats babies spend about twice the amt of time in sats <85%.

Next Meeting

- The SUPPORT Subcommittee will meet 4:15- 5:00 pm Easter on October 28 at the Steering Committee Meeting – This meeting will be closed to Subcommittee members and DCC staff.

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

Date: Tuesday, October 13, 2009 12:55:17 PM

Maybe we should discuss. It is difficult to schedule an ophthalmologist for a long call.
I'm not clear what the phone call should accomplish.
If it is planning the adjudication, that would be fine.
If it is the actual adjudication, I don't think we're ready.
Dale

Dale
The primary outcome is death or ROP at status or 55 weeks as written in the protocol. Any child without an eye outcome is considered "missing.". The adjudication is for a secondary analysis of the data using assumptions based on the excams available. Let me know if this helps. I will be in the office tomorrow and can give you a call.

Thanks
Rose

Hi Rose,
I have concerns.

You only have one ophthalmologist. David Wallace can not be the only person in the group that has the clinical experience to make these judgements.
A phone call is a very inefficient use of time for these judgments . Especially with that many people, I don't think it will work well.
But maybe this is just a planning session?

David has identified 5 other ophthalmologists form our NRN centers that he thinks would be good. I will include his list. I have a partial draft letter, not sent, for them [attached] because I was waiting to talk to Abhik and Rose and Kris about how we would do this. Maybe you have decided already ???
Sharon Freedman here at Duke is excellent, and she knows plus disease. Which centers are in

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

the Network?
David

Dale, From the list, I recommend 4 others (should make 6 if all agree):
Hutchinson
Hoffman
Neely
Yang
David

The Adjudication committee can not make a judgment about the primary outcome.
We have not established what the process will be, and that should be done before cases are examined.
I can help you a lot with how to present the data to the adjudication committee so that they can most efficiently absorb it.

Subject: NICHD NRN SUPPORT TRIAL ROP data adjudication conference call

Dear all,

We will have the NICHD NRN SUPPORT Trial data lock on 10/20/09 and would like to ask that you be part of an adjudication committee to determine acute final ROP status (if possible) for cases that are not straight forward. We would like to have this conference call on **Friday, October 23, 2009 from 3:00 = 5:00PM (EST).** We would be sending the data for case reviews on 10/22/09. Currently, there are about 50 cases where the infant had one exam in zone 3 (instead of the two consecutive exams required to meet our final status requirement) and about 50 who only had exams in zone 2. The study subcommittee may determine these later cases are classified as undetermined per the study manual definition but after data lock we will have a better idea of cases needing review. I have attached the study manual for reference.

Please let me know if you are willing and available this date and time.
Thanks,
Kris

Dear ...

Dr. David Wallace is helping us perform a review of ROP outcomes from a Randomized Controlled Trial conducted by the NICHD Neonatal Research Network. He has recommended you from the list of participating ophthalmologists at the 20 centers. We would like to invite you help us in this review.

The Study:

In a randomized study of ventilator practices and double-masked administration of two different levels of oxygen saturation, extremely preterm infants have been followed for the primary outcomes of ROP and chronic lung disease.

The Issue:

While most infants have had a final ROP outcome determined, some are in limbo. (failed to return for follow up, expired, missed exams with late follow up, etc.) The primary outcome is missing for these infants. However, a secondary outcome is useful for secondary analyses in such cases. These secondary analyses help to support the primary analysis of the trial, or determine the limitations of the analysis if they contradict the primary outcomes. They are very useful.

Your Role:

You would be asked to assign each case to one of the three outcomes:

1) Probably never had ROP that met criteria for ROP intervention (laser/cryo) in either eye
2) Probably did meet criteria for ROP intervention in at least one eye
3) There is no way to know if ROP criteria may have been met

How it would work:

For each case, a summary of all ROP examinations along with basic demographic data and follow up ophthalmic data would be provided to you and the other reviewers. You would not know which group the infant was assigned to. You would not know in which center the infant was cared for.

You would score each case, not discussing it with anyone else.

Your scores would be returned to the Data Coordinating Center.

If there was consensus on a case, the consensus secondary outcome would be assigned.

If there was disagreement, depending on the number of disputed outcomes, there would be a conference call or in-person meeting to reach resolution.

Hi Rose!

Our site had no quads, although we did have twins and triplets. Unless multiples are somehow linked with a specific non-anonymized study site, it seems that subject anonymity should be preserved (at least for our enrollees) since 17 sites are involved. If there is no linkage of the data with our specific site, we do not anticipate having a problem.

Roger

Subject: NEOProm meta analysis of oximetry trials

Hi,
Lisa Askie, who is leading the prospective meta analysis of the oximetry trials for which we are participating from the SUPPORT Trial is asking for birth order and sibling match to be included in the final data set. We do have information on birth order and sibling match in our data; however, there is a question of whether we can share that information due to privacy issues. For example,

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

if there is a set of quadruplets that might be a rare enough occurrence that sharing the information would make the infants identifiable. There is the additional complication that cases of multiple births in SUPPORT were randomized as a group (the pregnancy, not the infant, was the unit of randomization).

Please let me know if you are able to share this information on patients in the study of potentially triplets or even higher order multiples for the individual patient meta analysis. If you need to consult your IRB, please do so.

Please send me a response by October 23.

Thanks
Rose

Subject: NICHD NRN SUPPORT TRIAL ROP data adjudication conference call
Date: Monday, October 12, 2009 2:48:15 PM
Attachments: SUPPORTManual20071015.doc

Dear all,

We will have the NICHD NRN SUPPORT Trial data lock on 10/20/09 and would like to ask that you be part of an adjudication committee to determine acute final ROP status (if possible) for cases that are not straight forward. We would like to have this conference call on **Friday, October 23, 2009 from 3:00 = 5:00PM (EST).** We would be sending the data for case reviews on 10/22/09. Currently, there are about 50 cases where the infant had one exam in zone 3 (instead of the two consecutive exams required to meet our final status requirement) and about 50 who only had exams in zone 2. The study subcommittee may determine these later cases are classified as undetermined per the study manual definition but after data lock we will have a better idea of cases needing review. I have attached the study manual for reference.

Please let me know if you are willing and available this date and time.
Thanks,
Kris

Chapter 1

Overview and Trial Design

1.1 Introduction

This manual provides detailed instructions for study procedures related to The SUrfactant Positive Airway Pressure and Pulse Oximetry Trial in Extremely Low Birth Weight Infants (SUPPORT Study): The manual is meant to serve as a reference guide for study staff including investigators, coordinators, technicians, and data managers. The trial objectives and design are summarized briefly below. For further discussion to the study background and design, please refer to the protocol dated August 28, 2004.

1.2 Study Design

This will be a prospective, randomized, factorial 2X2 design multi-center trial conducted by the NICHD Neonatal Research Network. The individual factors to be tested will be:

1) A prospective comparison of CPAP and a permissive ventilatory strategy begun in the delivery room and continuing in the NICU with early (≤ 1 hour) surfactant and mechanical ventilation.
2) A prospective comparison of a lower SpO2 range (85% to 89%) with a higher more conventional SpO2 range (91% to 95%) until the infant is no longer requiring ventilatory support or oxygen.

The oxygen saturation monitoring portion of this study will be designed to parallel the planned POST-ROP trial, a multi-center, multinational prospective trial to evaluate different SpO2 levels from birth. The methodology described under oxygen monitoring (**Section 4.1B**) was developed for the current protocol to allow a blinded comparison of 2 different SpO2 levels using specially designed pulse oximeters. These devices will be developed by the Masimo Corporation (Irvine Ca) and tested prior to initiation of this trial, and the POST-ROP study group has agreed to use the ranges described in this protocol, and the methodology that will allow the oximeters to provide actual SpO2 values when the SpO2 is < 85% and > 95% (Personal communication, Cynthia Cole 2004). This methodology will provide the clinicians and caretakers with the infants' actual SpO2 values during hypoxia and hyperoxia, within the current parameters of clinically accepted practice.

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

Please refer to **Section 8.2** of the Protocol for further Tables describing details regarding the projected outcomes relative to the study interventions

Randomized Intervention	Low SpO2 85% to 89%	High SpO2 91 to 95%
Treatment **Early CPAP**	Early CPAP + Low SpO2	Early CPAP + High SpO2
Control **Prophylactic/Early Surfactant**	Control + Low SpO2	Control + High SpO2

1.4 Primary Hypothesis

1) We hypothesize that relative to infants managed with prophylactic/early surfactant and conventional ventilation that the use of early CPAP and a permissive ventilatory strategy in infants of less than 28 weeks gestation with continuing CPAP in the NICU will result in an increased survival without BPD at 36 weeks.

2) We hypothesize that that relative to infants managed with a higher SpO2 range that the use of a lower SpO2 range (85% to 89%) will result in an increase in survival without the occurrence of threshold ROP and/or the need for surgical intervention.

1.5 Secondary Hypotheses

We hypothesize that the use of continuous positive airway pressure (CPAP) with a permissive ventilator strategy and/or a lower SpO2 range starting at birth in the delivery room will result in the following:

- A decreased Mortality/NDI at 18-22 months corrected age.
- A decreased frequency of endotracheal intubation before 10 minutes of age
- A decrease of the total duration of mechanical ventilation during the entire NICU stay
- A decreased incidence of surfactant treatment
- A decreased incidence of air leaks on admission and overall
- A decreased duration of intubation
- A decreased duration of mechanical ventilation
- A decreased duration of oxygen supplementation
- A decreased duration of the percentage of pulse oximetry values > 90%
- A decreased incidence of blindness of at least one eye at 18-22 month follow-up
- A decrease in the percentage of infants who receive postnatal steroids to prevent or treat BPD
- A decreased incidence of BPD at 36 weeks using the physiologic definition of BPD

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

- A decreased incidence of ROP or Stage 3 ROP
- A decreased incidence of necrotizing enterocolitis (NEC)
- A decreased incidence of IVH and severe IVH
- A decreased incidence of periventricular leukomalacia
- A decreased incidence of neurodevelopmental impairment at 18-22 month follow-up
- A decreased incidence of cerebral palsy at 18-22 month follow-up

1.6 Summary of Data Forms

The following is a summary of the data forms used in this study. Further details on each form are provided in subsequent chapters. A complete set of forms can be found in Appendix A.

Screening Log (SUPP01)
A Screening Log (SUPP01) is provided to facilitate the tracking of infants with gestational age 27 6/7 weeks or less for whom a decision has been made to provide full resuscitation as necessary in the Network centers.

Eligibility Form (SUPP02)
This form will be completed for all inborn infants with a minimal gestational age of 24 weeks 0 days to 27 6/7 completed weeks by best obstetrical estimates and who are to receive full resuscitation as necessary.

Delivery Room Form (SUPP03)
Data for this form will be collected in the delivery room and will be completed on all infants.

NICU Admission and Procedures Form (SUPP04)
This form is to be completed on all infants enrolled in the study upon admission to the NICU.

NICU Admission and Procedures Form (SUPP04a- Surfactant Doses)
This form is to be completed if more that 4 surfactant doses are given between the first dose in the NICU and day 14 of study.

Safety Monitoring Form (SUPP05)
This form is to be completed each day starting with Study day 1 until Study day 14 or outcome status, whichever comes first.

Safety Monitoring Form (SUPP05A)
This form is to be completed each time an intubation/extubation occurs after admission to the NICU through day of life 14.

Replacement Oximeter Form (SUPP05B)
This form is to be completed each time a study oximeter is replaced from study initiation to 36 weeks or status (whichever comes first).

Protocol Deviation Form (SUPP06)
This form will be completed for all randomized patients whenever a protocol deviation/violation is encountered.

Reintubation Form (SUPP07)
This form will be completed for all intubation/extubations after 14 days.

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

Adverse Event Form (SUPP08)
This form will be completed for the adverse events, as specified in the protocol, occurring during the initial 14 days of life.

MedWatch Form (SUPP08A)
This form is to be completed in the event of a serious adverse event. It should be faxed to Ken Poole (919) 485-7762 and Rosemary Higgins (301) 496-3790 within 24 hours or the next working day.

Outcome Status Form (SUPP09)
This form will be completed when the infant is discharged home, transferred, if hospitalized at 120 days, death or withdrawn (whichever comes first).

ROP Outcomes and Tracking Summary (SUPP10)
The form will be used to record data for each eye examination (in or outpatient) until both eyes are acute/final.

Respiratory Support After 14 Days (SUPP11)
This form is to be completed daily from study day 15 through 36 weeks or status, whichever comes first.

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

Chapter 2

Administration

2.1 Organizational Structure

The NICHD Neonatal Research Network is conducting this study. The Network is funded by the NICHD under cooperative agreements with seventeen institutions comprised of sixteen clinical centers and a data coordinating center. The Steering committee for the Network consists of the Principal Investigator from each clinical center, the data center, and the NICHD project officer. The Steering Committee Chairman is appointed by NICHD and is not a Principal Investigator from any of the Clinical Centers.

2.2 SUPPORT Trial Subcommittee

The SUPPORT Protocol Subcommittee is responsible for the preparation and maintenance of the protocol, data forms, and manual of operations. This subcommittee will monitor the overall study performance (including protocol compliance) and will report the progress of the trial to the Steering Committee. SUPPORT Subcommittee members are:

Neil Finer, MD

Waldemar A. Carlo, MD,

Michele Walsh, MD

Abbot Laptook, MD

Kurt Schibler, MD

Bradley Yoder, MD

Roger Faix, MD

Rosemary D. Higgins, MD

Abhik Das, PhD

Marie Gantz, PhD

Nancy Newman, RN

Wade Rich, RRT

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

2.3 Participating NICHD Neonatal Research Network Centers

Centers from the NICHD Neonatal Research Network participating in the trial are listed below. The NICHD center number is indicated in parentheses next to the name of each center and the principal investigator is located in the second column.

PARTICIPATING CENTERS	NRN PI	SUPPORT STUDY PI
Case Western Reserve Univ. (3) Rainbow Babies and Children's Hospital	Michele Walsh, MD	Michele Walsh, MD
University of Texas-Dallas (4)	Pablo Sanchez	Pablo Sanchez
Wayne State University (5) Children's Hospital of Michigan	Seetha Shankaran, MD	Seetha Shankaran, MD
Emory University (9) Grady Memorial Hospital	Barbara J. Stoll, MD	Susie Buchter, MD
University of Cincinnati (11) University of Cincinnati Hospital	Kurt Schibler, MD	Vivek Narendran, MD
Indiana University (12)	Brenda Poindexter, MD	Brenda Poindexter, MD
Yale University (13) The Children's Hospital at Yale – New Haven	Richard A. Ehrenkranz, MD	Vineet Bhandari, MD
Brown University (14) Women and Infant's Hospital	William Oh, MD	Abbot Laptook, MD
Stanford University (15) Stanford University Med Center	Krisa Van Meurs, MD	Krisa Van Meurs, MD
University of Alabama (16) University of Alabama at Birmingham	Waldemar A. Carlo, MD	Waldemar A. Carlo, MD
University of Texas- Houston (18)	Kathleen Kennedy MD	Brenda Morris, MD
Duke University (19)	Ronald Goldberg, MD	C. Michael Cotten, MD
University of California-San Diego (22)	Neil Finer, MD	Neil Finer, MD
Tufts NEMC (23)	Ivan Frantz, MD	Ivan Frantz, MD
University of Iowa (24)	Edward Bell, MD	Edward Bell, MD
University of Utah (25)	Roger Faix, MD	Bradley, Yoder, MD
University of New Mexico (26)	Kristi Watterberg, MD	Kristi Watterberg, MD

2.4 Responsibilities of the Clinical Centers

The minimum staff required for network participation at each clinical center is the physician Principal Investigator (PI), the Research Coordinator, and a small number of unmasked personnel who will provide 24 hour coverage to monitor study equipment.. The responsibilities of these individuals are described briefly in this chapter and in more detail in subsequent chapters.

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

The PI or designee is responsible for ensuring the proper conduct of the trial at his or her clinical center (including recruitment and treatment of patients as specified in the protocol), accurate collection of data and transmission of information to the Data Coordinating Center (DCC). Other specific duties include the following:

- Presenting an in-service to the other physicians
- Applying for IRB approval
- Introducing the study to the parents of prospective patients, and obtaining signed informed consent from the parents of eligible infants (in some centers this responsibility may be delegated)
- Reviewing all infants for whom informed consent has been obtained to confirm their eligibility
- Informing the IRB of the study progress.

The Research Coordinator will be responsible for the day-to-day operations of the study at the clinical center, including data collection and management. This responsibility includes the following:

- Presenting an in-service to the appropriate nursing and ancillary staff detailing the study protocol
- Collecting information necessary to complete the data collection forms, and coordinating data entry
- Training and certifying the staff in the use of the network microcomputer
- Controlling access to the network microcomputer and ensuring that required back-up, security and confidentiality are maintained
- Responding to edit messages and other communications from the data center
- Distributing updates of the protocol and of the manual of operations to clinical center staff
- Achieving and maintaining fluency with the procedures for obtaining the treatment group assignment from the data center
- reporting deviations to the data center within 24 hours of occurrence

2.5 Responsibilities of the Data Coordinating Center

The DCC is responsible for all aspects of statistical design and analysis as well as data management of the study. In particular, this includes:

- Processing, updating and distributing the protocol and manual of operations
- Developing, printing and distributing the data forms, including periodic updates as necessary
- Developing, testing and implementing the database and other software. Ensuring that data are correct and complete by implementing editing and auditing procedures
- Monitoring the progress and quality of the study
- Preparing interim and final analyses and reports
- Participating in the preparation of presentations and publications relating to the study.

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

2.6 Responsibilities of NICHD

In addition to its role as a funding agency, the NICHD participates in the activities of the cooperative agreement by being represented on the Steering Committee. The Program Official also participates in the development of protocol and in assisting the Steering committee in the coordination of the studies conducted by the Network. The NICHD Program Official, in conjunction with the RTI Principal Investigator is responsible for monitoring site performance of all participating centers. The Program Official has the following responsibilities:

- Assistance in the development of the study protocol.
- Assistance in the development of capitation-based budgets, including the identification of study costs and special institutional needs.
- Allocation of network resources to meet study needs including pharmacies, study drug supply, and other special requirements of the study.
- Facilitation of training meetings, site visits, and subcommittee meetings.
- Participating in preparation of publications.

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

Chapter 3

Screening, Eligibility, Consent

3.1 Study Population

Study subjects are inborn infants of 24 0/7ths to 27 6/7th weeks at birth for which a decision has been made to provide full resuscitation as required. Infants 27 weeks or less gestation (completed weeks by best obstetric estimate) will be enrolled.

3.2 Inclusion Criteria

- Infants with a minimal gestational age of 24 weeks 0 days to 27 completed weeks (up to 27 6/7ths) by best obstetrical estimate
- Infants who will receive full resuscitation as necessary, i.e., no parental request or physician decision to forego resuscitation
- Infants without known major congenital malformations

3.3 Exclusion Criteria

- Any infant transported to the center after delivery
- Infants born during a time when the research apparatus/study personnel are not available

3.4 Informed Consent

Infants will be recruited for this study by approaching one or both parents at the time of admission to the hospital at risk for premature delivery at 27 weeks or less. It is anticipated that, whenever possible, the parents will be approached by study personnel to discuss the trial and obtain an informed consent for the participation of the infant at delivery. As discussed in Section 4.1, randomization will be by family, thus all offspring will be randomized to the same trial arms, provided adequate equipment and personnel are available at the time of delivery.

3.5 Screening Procedures

All admissions for threatened premature delivery will be screened on a daily basis to ensure that eligible patients can be enrolled. Obstetrical colleagues at each participating institution will be informed of the nature of this study and encouraged to discuss this study with their patients at risk of premature delivery. The study coordinator at each site will maintain a screening log of potentially eligible patients. In addition the usual practice of neonatal consultation for all such at risk deliveries will provide a second opportunity to approach mothers with fetuses at risk of preterm delivery.

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

Chapter 4

Randomization

4.1 Randomization Procedures

Randomization will be stratified by gestational age group (24 - 25 6/7 and 26 - 27 6/7) and will occur prior to delivery for consented deliveries. The randomizations will be performed by **utilizing specially prepared envelopes**. The Data Center will prepare brown sealed envelopes which will contain the identity of the treatment combination to be assigned the infants enrolled into the study. **Deliveries will be randomized as a unit, thus multiples, twins, triplets etc will be randomized to the same arm of the trial.** One envelope will correspond to the delivery of a consenting mother regardless of the number of babies delivered so that all babies from a given delivery will receive the same treatment combination.

4.1.1 Randomization and Masking, Storing and Assigning Oximeters

Two sets of envelopes will be used; one for the gestational age group 24 -25 6/7 weeks and one for the 26 - 27 6/7 week gestational age group. These should be kept in separate boxes or drawers with the group clearly indicated **(this will be noted on the label on the front of the envelope).** The envelopes will be sequentially numbered with a randomization number on the outside of the envelope so they can be selected in the order of use to maintain a balancing of the treatment assignments. These envelopes are to be stored in a secure place in or near the delivery for quick accessibility.

The envelope should be selected, from the appropriate group, and opened at the time of delivery by a study staff member only when the delivery is imminent. Inside the sealed envelope will be a white card which will contain the randomization number and treatment assignments. The card will indicate which of the Early CPAP/Early Surfactant treatments is selected and will indicate a color code for the High/Low SpO2 arm of the study. They will be specified as one of the following:

- **Treatment Group** (EARLY CPAP and permissive ventilation management) with an **Oximeter code** of either **Blue or Orange**
  OR
- **Control Group** (Early SURFACTANT and conventional ventilator management) with an **Oximeter code** of either **Blue or Orange.**

The **Blue/Orange codes** will designate an assignment to either the **Low (85% - 89%)** or **High (91% - 95%)** SpO2 group. The oximeters will be shipped directly to the clinical sites from Masimo. The Data Center will supply the sites with the **Blue and Orange** labels and these color coded labels will correspond to the serial numbers on the oximeter(s). The serial number(s) will need to be recorded on the appropriate data form (**SUPP04 Form**).
Note: The oximeters should be stored in such a manner that the individual who will be obtaining them and returning them to their original location can easily identify which oximeters belong to which color-coded randomization group. It is not recommended that the oximeters be

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

identified with the blue or orange colored labels. A system whereby the serial numbers for each color group are identified at the storage sight, along with a list of which infants have been placed on which serial numbers, makes it possible to track oximeters without using the color coded labels on the devices themselves.

The person opening the envelope should announce to the team the assignment of the Early CPAP/Early Surfactant arm of the study. Someone should then take the opened envelope to the secure area where the oximeters are stored and select the oximeter (s) whose color code is specified in the randomization envelope. **Once the envelope is opened, it should be stored in a secure location only accessible to staff with "a need to know".** Randomization should be done only if sufficient numbers of oximeters of both types (i.e. high and low SpO2) are available to accommodate the delivery.

Once the use of an oximeter has been completed, it should be returned to the color coded location for storing the inventory of oximeters (e.g., a color coded shelf) checking to be sure that the serial numbers match. A log should be maintained to record the date and time the particular oximeter is returned to this location.

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

Chapter 5

Study Interventions

5.1 Study Intervention A

5.1.1 Mode of Ventilatory Support

The intervention will begin after birth when the infant is given to the resuscitation team. The conduct of the resuscitation will follow usual guidelines. Once stabilized:

- All **Control infants** in both strata will receive prophylactic/early surfactant (within 1 hour of age).
- All **Treatment infants** will be placed on CPAP/PEEP following stabilization, and will be intubated only for resuscitation indications.

The assignment to either a high or low SpO2 by **Study Oximeter Assignment** will be performed immediately following NICU admission, with a maximum allowable delay of 2 hours following NICU admission.

Treatment Groups

5.1.2 CPAP Group: Early Extubation and CPAP – Both Strata

5.1.3 Delivery Room Management

1) FiO2:
Standard of care

2) CPAP:
CPAP or ventilation with PEEP will be utilized if the infant requires positive pressure during resuscitation. CPAP will be continued until admission to the NICU using the Neopuff or equivalent device and a face mask or nasal prongs. Initial PPV will be at a PIP of 15-25 cm H_2O and a PEEP/CPAP of 5 cm cmH_2O. High flow nasal cannula (e.g. Vapotherm) may not be used as the primary mode of therapy for infants randomized to Early CPAP in the first 14 days.

3) Intubation:
Infants may not be intubated for surfactant only in the DR. Infants who require intubation for resuscitation will receive surfactant within 60 minutes of birth. Intubation will be performed only for the standard NRP indications including failure to respond to PPV with evidence of continuing cyanosis or bradycardia, the need for chest compressions, the need to administer intratracheal medications, or other situations in which the resuscitation team determines that surfactant is urgently required.

Intubation may be performed at any time for the occurrence of repetitive apnea requiring bag and mask ventilation, clinical shock, sepsis, and/or the need for surgery

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

The other aspects of the resuscitation will be managed according to the NRP guidelines and follow current center practice.

5.1.4. NICU Management

These infants will be managed on nasal CPAP and intubation is never required by protocol. They ***MAY*** be intubated if they meet ***ANY*** of the criteria listed below. If intubated within the first 48 hours of life they should receive surfactant.

1. **Intubation:**
   - An FiO_2 >.50 required to maintain an indicated SpO2 $\geq$ 88% (using the altered Pulse Oximeters) for one hour
   - A $PaCO_2$ > 65 torr (arterial or capillary samples, if venous PvCO2 > 70 torr) documented on a single blood gas
   - Hemodynamic instability defined as a low blood pressure for gestational age and/or poor perfusion, requiring volume and/or pressor support for a period of 4 hours or more. (Note that clinically defined shock is an accepted indication for intubation.)

Intubation may be performed at any time for the occurrence of repetitive apnea requiring bag and mask ventilation, clinical shock, sepsis, and/or the need for surgery

These criteria will continue in effect for a minimum of 14 days of life.

Intubation performed without meeting any of the above criteria will be considered a study protocol violation unless extenuating circumstances are noted.
(e.g. - Upper airway obstruction (choanal atresia, micrognathia/glossoptosis)).

2. **Extubation:**

An intubated CPAP-Treatment infant ***MUST*** have extubation attempted within 24 hours if ***ALL*** of the following criteria are met and documented on a single blood gas:

- $PaCO_2$ < 65 torr with a pH > 7.20 (arterial or capillary samples)
- An indicated SpO2 $\geq$ 88% with an FiO2 $\leq$ 50%
- A mean airway pressure (MAP) < 10 cm H_2O, ventilator rate $\leq$ 20 bpm, an amplitude < 2X MAP if on high frequency ventilation (HFV)
- Hemodynamically stable (Defined as an infant with clinically acceptable blood pressure and perfusion in the opinion of the clinical team – such an infant may be receiving ionotropic/vasopressor agents, but should not require ongoing volume infusions to stabilize the circulation and the doses of any continuously infused medications for circulatory stabilization should not have increased within 1 hour of any planned extubation).
- Absence of clinically significant PDA

These criteria will continue in effect for the first 14 days of life.

*Failure to extubate an infant meeting all of the above criteria will be recorded as a study protocol violation (**on the SUPP06 Form**) unless extenuating circumstances are noted (e.g. PIE, airleak).*

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

3. Reintubation

If a Treatment infant is extubated as per Protocol Criteria, and requires re-intubation for any indication, any further attempt at extubation may be delayed for 24 – 48 hrs based on the clinician's decision.

Re-intubation criteria are the same as those for Intubation for the CPAP infants. Thus, intubation is not required, but these infants ***MAY*** be reintubated if they meet ***ANY*** of the following:

4. Re-Intubation Criteria:

- An FiO_2 >.50 required to maintain an indicated SpO2 ≥ 88% (using the altered Pulse Oximeters) for one hour
- A $PaCO_2$ > 65 torr (arterial or capillary samples, if venous PvCO2 > 70 torr) on a single blood gas
- Hemodynamic instability defined as a low blood pressure for gestational age and/or poor perfusion, requiring volume and/or pressor support for a period of 4 hours or more. Note that clinically defined shock is an accepted indication for intubation.

Intubation may be performed at any time for the occurrence of repetitive apnea requiring bag and mask ventilation, clinical shock, sepsis, and/or the need for surgery.

Re-intubation performed without meeting any of the above criteria will be considered a study protocol violation unless extenuating circumstances are noted.

5. D/C CPAP

Treated infants who remain in Room Air for at least 1 hour may have their CPAP discontinued. CPAP may be discontinued earlier and follow unit Standard of Care. May be restarted at any time in such infants.

CPAP infants who require intubation three times, for any criteria, will have all subsequent treatment including subsequent extubations and any further re-intubations performed using unit Standard of Care. This addition is to prevent such infants from being exposed to further protocol driven intubations and extubations.

6. Surfactant

Infants intubated in the first 48 hours for respiratory distress should be given a minimum of one dose of surfactant. Up to 4 surfactant administrations may be given if the FiO2 is greater than 50% following manufacturers' recommendations for dose and dosing interval.

5.1.5 Explanation:

The purpose of the above criteria is to minimize the duration of intubation of Treatment infants. The Criteria for extubation are more severe than those of the Control Group infants, and extubation must be attempted for any infant who fulfills the stated criteria.

The criteria for re-intubation recognize that intubation is traumatic, and is designed to avoid frequent attempts at extubation for infants who fail.

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

5.1.6 Control Group- Prophylactic/Early Surfactant and Ventilation

5.1.7 Delivery Room Management:

Infants will be intubated in the delivery room and given surfactant or receive surfactant within 60 min minutes of birth. The other aspects of the resuscitation will be managed according to the NRP guidelines and follow current center practice.

5.1.8 NICU Management:

1. Extubation:

An intubated Surfactant-Control infant will continue to receive mechanical ventilation until extubation criteria are satisfied, but **MUST** have extubation attempted within 24 hours of fulfilling ***ALL*** of the following criteria documented on a single blood gas:

- $PaCO_2$ < 50 torr and pH > 7.30 (arterial or capillary samples)
- An FiO2 ≤.35 with a SpO2 ≥ 88% using the study pulse oximeters with
- A mean airway pressure (MAP) < 8 cm H_2O, ventilator rate ≤ 20 bpm, an amplitude < 2X MAP if on high frequency ventilation (HFO)
- Hemodynamically stable (Defined as an infant with clinically acceptable blood pressure and perfusion in the opinion of the clinical team – such an infant may be receiving ionotropic / vasopressor agents, but should not require ongoing volume infusions to stabilize the circulation and the doses of any continuously infused medications for circulatory stabilization should not have increased within 1 hour of any planned extubation).
- Absence of clinically significant PDA (Defined as bounding pulses, audible murmur and Echo confirmation of L-R shunting with increased LA/Ao size

These criteria will continue in effect for a minimum of 14 days for all infants.

Failure to attempt to extubate an infant meeting all of the above criteria, or extubation prior to reaching criteria, will be recorded as a study protocol violation ***(on Form SUPP06)*** *unless extenuating circumstances are noted.*

2. Weaning

This protocol will not define strict weaning criteria for the Control infants, but it is to be understood that reasonable attempts should be made to extubate these infants. While it is understood that some centers may be using somewhat more severe FiO2 and PaCO2 criteria than those listed here as current practice, these Criteria are thought to reflect current Network practice and practice at 2 of the 3 Best practice centers.

3. Reintubation:

- Control Infants may be reintubated using Standard of Care. Any subsequent extubations will also follow standard practice.

5.1.9 Explanation:

Control infants are to be treated using an approach considered similar to current standards of care. Apparatus for resuscitation for Control Infants at each center will represent their usual equipment for the resuscitation of an ELBW infant. The Neopuff may be utilized for such infants

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

as above, but this is not mandatory. It is anticipated that the majority of these infants will be intubated and receive surfactant in the delivery room.

5.2 Study Intervention B

5.2.1 Low versus High SpO2 Range:

There will be 2 ranges of SpO2 utilized during this trial. The Low target range will be 85% to 89% and the High target range will be 91% to 95%. The altered Pulse Oximeters (PO) as described below will display a range of 88% to 92% when the SpO2 ranges are in the Target ranges indicated above. Thus a Low range PO will read 88% when the actual SpO2 is approximately 86%, and 92% when the actual SpO2 is 89%. Similarly the High range PO will display 88% when the actual SpO2 is 91% and indicate 92% when the actual SpO2 is approximately 95%. As an added safety feature, the POs used in this trial will gradually revert to the actual SpO2 values and allow the caretakers to be aware of actual SpO2 values < 85% and > 95%.

5.2.2 Low Range Infants:

These infants will be monitored with a target SpO2 range of 85% -89% with suggested indicated alarm limits of 85% and 95%, representing approximately a 10% span for alarms as long as the infants are receiving any ventilatory support, CPAP, and/or supplemental oxygen.

The study pulse oximeters will be applied to the infant within two hours following NICU admission. The assigned PO will remain on the infant and will be removed once the infant has been in room air and off ventilatory support or CPAP for 72 hours, and if oxygen is subsequently required a similar altered pulse oximeter providing the same SpO2 range will be used until 36 weeks PCA.

5.2.3 High Range Infants:

These infants will be monitored with a target SpO2 range of 91% -95% with suggested indicated alarm limits of 85% to 95% representing approximately 10% span for alarms as long as they are receiving any ventilatory support, CPAP and/or supplemental oxygen.

The study pulse oximeters will be removed once the infant has been in room air for 72 hours, and if oxygen is subsequently required a similar altered pulse oximeter providing the same SpO2 range will be used until discharge 36 weeks PCA.

These interventions will be delivered using specially developed pulse oximeters whose displays will be adjusted so that the randomized range of SpO2 (either 85%-89%, or 91%-95%) will be indicated by a range of 88%-92%. These POs will be able to display trend plots of the SpO2 display for a preceding interval to allow the caretakers to receive feedback regarding the actual SpO2 ranges of their baby.

The suggested alarms limits will be 84% to 96% for both groups. All values outside of alarm limits will be unaltered values.

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

The target oxygen saturation (88-92%) of the display will be the same in both groups as indicated in Table 1 below.

Table 1

Output and Actual SpO2 Targets and Alarms

Group	Display Target	Actual Target	Alarm Values
Low SpO2 range	88-92%	85-89%	<85 and >95%
High SpO2 range	88-92%	91-95%	<85 and >95%

Every 30 days until 36 weeks PCA, or until the infant is no longer receiving ventilatory support or oxygen, the stored actual SpO2 values (one value per 10 seconds of monitoring) will be downloaded and transmitted to RTI for subsequent analyses to determine that were are within the desired ranges. (This interval of sampling may change to a less frequent interval for the convenience of the study personnel, without loosing significant data). These data points will be used to confirm that the infants were managed at the target ranges and provide objective confirmation of the SpO2 Group assignments. The technology for downloading and interpreting this data was used in the DR CPAP Pilot trial, but recent technology utilizing a software program (Profox, Profox Inc, Escondido, Ca) which has been written to facilitate this process, will dramatically simplify this procedure.

All ventilatory care after 14 days of age will follow the standard of care for each unit. Each unit will provide guidelines for their approach to continuing mechanical ventilation.

See Flow of Study Intervention on page 5.7:

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

Flow of Study Intervention

	Early Extubation and CPAP	Prophylactic/Early Surfactant and Ventilation
Delivery Room Management:	• Resuscitate using CPAP. If necessary, initial PPV settings PIP 15-25, PEEP 5. • Transport on CPAP **If intubated for resuscitation** • Give surfactant within 1 hour of age. Do not intubate unless indicated by NRP guidelines	• Intubate and give surfactant within 1 hour of age • Transport with PPV according to SOC
Upon NICU Admission:	Randomize within 2 hours to Pulse Oximeter	Randomize within 2 hours to Pulse Oximeter
Intubation Criteria:	**May intubate for ANY of these criteria** • FiO_2 >.50 required to maintain indicated SpO2 ≥ 88% (using the altered Pulse Oximeters) for one hour • $PaCO_2$ > 65 torr (art. or cap. samples, if venous $PaCO_2$ > 70 torr) documented on a single blood gas • Hemodynamic instability defined as a low blood pressure for gestational age and/or poor perfusion, requiring volume and/or pressor support for a period of 4 hours or more. **If intubated, give surfactant within the first 48 hrs if in respiratory distress**	**Reintubation Criteria:** **Standard of Care**
Extubation Criteria:	**Attempt extubation within 24 hours of fulfilling all of the following criteria:** • $PaCO_2$ < 65 torr with a pH > 7.20 (arterial or capillary samples) • An indicated SpO2 ≥ 88% with an FiO2 ≤ 50% • Mean airway pressure (MAP) < 10 cm H_2O, vent rate ≤ 20 bpm, amplitude < 2X MAP if on HFV • Absence of clinically significant PDA • Hemodynamically stable	**Attempt extubation within 24 hours of fulfilling all of the following criteria** • $PaCO_2$ < 50 torr and pH > 7.30 (arterial or capillary samples) • FiO2 ≤ 35 with SpO2 > 88% • Mean airway pressure (MAP) < 8 cm H_2O, vent. rate ≤ 20 bpm, amplitude < 2X MAP on HFV • Absence of clinically significant PDA • Hemodynamically stable
Repeated Surfactant Doses:	Subsequent doses may be given at the manufacturer's recommended dose up to a total of 4 doses.	
Intubation:	Intubation may be performed at any time for the occurrence of repetitive apnea requiring bag and mask ventilation, clinical shock, sepsis, and/or the need for surgery.	
CPAP D/C:	In room air for at least 1 hour	
CPAP Resumption:	At any time	
Duration of Intervention:	14 Days	14 Days

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

5.3 Delivery of Interventions

5.3.1 CPAP/PEEP in the DR

CPAP and positive pressure ventilation (PPV) in the delivery room for Treatment infants will be administered via a T-piece resuscitator a neonatal ventilator, or an equivalent device that is currently used by the site for the delivery of CPAP.

5.3.2 Use of Nasal SIMV

For uniformity nasal SIMV may be used in place of CPAP ***only following extubation*** for both Treatment and Control infants.

5.3.3 Use of Caffeine

Caffeine may be administered 2 hours prior to planned extubation, and for any clinically significant apnea.

5.3.4 Surfactant Type

All centers are asked to follow current unit practice in determining the type of surfactant utilized and manufacturers' recommendations for re-dosing intervals.

At least one dose of surfactant **must** be administered to any infant intubated within 48 hours of birth, with evidence of respiratory distress, who has not previously received surfactant.

5.3.5 Postnatal Steroids

Postnatal steroids for the purpose of preventing or treating BPD/CLD will be prohibited for any infant in this trial in the first 21 days of life. Hydrocortisone for hypotension may be used as noted below.

If postnatal steroid use is considered after 21 days of life for any infant for the prevention/treatment of established lung disease the following guidelines should be followed:

1. The AAP statement and recommendations regarding Post-natal steroids should be adhered to.
2. The lowest dose of dexamethasone considered effective should be used and if ineffective after 24 – 48 hours they should be stopped.
3. Consider using hydrocortisone as a first therapy at a dose of 1 -2 mg/kg/day before using dexamethasone.
4. For hypotension, hydrocortisone in a dose of 1 mg/kg/dose should be given after fluid administration and standard doses of ionotropes/pressors have failed to correct the low blood pressure.

5.3.6 Head Ultrasound

If a Head ultrasound is done between days 4 and 21 the results will be recorded for this study. If one is not done for standard of care, the study requires that at least one HUS be completed during this window.

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

5.4 Protocol Violations

The occurrence of any one of the following criteria will determine whether an individual infant will be considered a protocol violation:

1. Intubation of an Early Extubation and CPAP infant in the DR for the exclusive purpose of giving surfactant, in the absence of bradycardia (HR< 100 bpm) and/or poor color or an SpO2< 85-90% in an infant with adequate spontaneous respirations or receiving adequate ventilation
2. Failure to continue CPAP on admission to the NICU for an Early Extubation and CPAP infant requiring `supplemental oxygen
3. Intubation and surfactant administration of an Early Extubation and CPAP infant without meeting stated protocol criteria.
4. Failure to extubate an Early Extubation and CPAP infant who fulfills all the extubation criteria.
5. Extubation of a Prophylactic/Early Surfactant and Ventilation infant who does not meet any of the extubation criteria.

All protocol violations will be reviewed by the center PI who will discuss each protocol violation with the involved clinicians and provide a written summary including steps taken to avoid future violations. The Protocol Violation/Deviation Form (SUPP06) should be completed each time a violation/deviation is encountered.

5.5 Adverse Events

Serious and unanticipated adverse events may be anticipated in this vulnerable population. Data on the following potential adverse events that may be related to the study maneuver will be recorded and evaluated as part of continuous safety monitoring during the trial by RTI:

1. Air leak on admission to the NICU, or during the initial 14 days of life
2. The need for chest compressions, and/or epinephrine in the delivery room or NICU
3. The occurrence of severe IVH (Grades III-IV, Papile)
4. Pulmonary hemorrhage
5. Nasal breakdown requiring discontinuation of nasal prongs
6. Death

These outcomes will be evaluated on a monthly basis by RTI using sequential analysis boundaries, and if the incidence of any of these outcomes differs among the treatment arms of the study this information will be provided to the DSMC for immediate evaluation and consideration of termination of the study or treatment arm. The SUPPO8 (Medwatch Form) should be completed in the event of a serious adverse event. It should be faxed to RTI (919) 485-7762 and Rosemary Higgins (301) 496-3790 within 24 hours or the next working day.

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

Chapter 6

Screening Log

6.1 Instructions for completing the Screening Log (SUPP01)

Each center will implement an effective and efficient screening procedure to identify all potential study subjects. A Screening Log (SUPP01) is provided to facilitate the tracking of infants with gestational age 27 weeks or less for whom a decision has been made to provide full resuscitation as necessary. The following information is used to identify each infant and is placed on the screening log.

Center Number
Each study center has been assigned a Network center number.

Site
Centers with more than one participating hospital also have a site code (A, B, C or 1, 2, 3).

THE FOLLOWING INFORMATION WILL BE FILLED OUT WHEN THE MOTHER IS FIRST SCREENED:

Mother's Last Name
The last name of the mother who is being screened should be written on this log. This confidential information is recorded for the convenience of the center and must not be submitted to the DCC.

Mother's Hospital Number
The hospital number of the mother should be recorded. This confidential information is recorded for the convenience of the center and must not be submitted to the DCC.

Gestational Age
Record the actual gestational age in weeks and days when the mother is identified.

Last Date Eligible
Record the date this mother will reach 27 6/7 completed weeks. This will be the date when her infant would no longer be eligible for enrollment in this study. This will be used as a guide to track a mother who may be at risk for premature delivery but who may not deliver within the window of the study.

Consent
Record 'Y' or 'N' if consent has been obtained. If consent is obtained this pregnancy/infant birth will be followed to determine eligibility.

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

THE FOLLOWING INFORMATION WILL BE FILLED OUT ON THOSE PATIENTS WHO HAVE GIVEN CONSENT WHEN THE INFANT IS BORN WITHIN THE ELIGIBLE WINDOW:

Date of Birth

Enrolled in Study
Record 'Y' or 'N' if infant was enrolled in this study. This will ensure that all potential infant outcomes were identified (including but not limited to: enrolled in the study, gestational age at birth >28 weeks, died in delivery room).

Network Number

Record the Network number of any infant enrolled in the study.

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

Chapter 7

Eligibility Form

7.1 Instructions for completing the Eligibility Form (SUPP02)

Heading- Infant's Identification
The following information is included in the heading section of all patient specific data forms: Center, Site, Network Number, Birth Number and Mother's Initials **(optional).**

7.1.1 Form Section A: Eligibility Criteria

If any criteria are not met, the infant is ineligible.

1. Inborn infant with a gestational age of 24 weeks 0 days to 27 6/7th completed weeks by best obstetrical estimate?
Code yes if the infant was 27 completed weeks or less by best obstetrical estimate or by appropriate clinical examination.

2. Infants who will receive full resuscitation as necessary?
Code yes if the infant will require full resuscitation as necessary

3. Infant who does not have know major congenital malformations?
Code yes if the infant does not have known major congenital malformations.

If any of the above questions are answered No the infant is NOT eligible.

7.1.2 Form Section B: Exclusion Criteria

1. The infant was born during a time when the research apparatus/study personnel are not available?
Code yes if there was no apparatus/study personnel available.
If Yes, indicate the reason:
1= Equipment not available
2= Personnel not available

7.2 Form Section C: Consent

Sample consent forms for this study are included in Appendices D and E.
Consent status:

Answer this question with one of the following codes, according to the following definitions:

0 = Not Eligible
Code '0' if one or more of the eligibility criteria questions are answered "No". If the infant is ineligible, regardless of whether consent was granted or not, this code should be used.

1 = Consent Granted
Code '1' if parenteral/guardian consent is obtained.

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

2 = Parent Unavailable
Code '2' if the parent or legal guardian is unavailable throughout the eligibility period

3 = Parent Refused Consent
Code '3' if a parent or legal guardian refuses consent.

4 = Consent Not Requested
Code '4' if consent for this study was not requested. Language or social problems as well as enrollment in conflicting trials should be recorded here.

5 = Physician Refused Consent
Code '5' if the infant was eligible for the study, but the attending physician refused to consider the baby for enrollment.

If the consent status is 3, 4, or 5, indicate the reason why consent was refused or not requested.

If the patient is eligible and consent is granted, but the patient is not randomized, indicate the reason why the eligible infant was not randomized into the study although consent from both parent/guardian and physician was obtained.

7.3 Form Section D: Randomization

An infant is eligible for randomization if all eligibility criteria are answered Yes in Section A. The infant is considered randomized at the time the randomization number is given.

1. **Was infant randomized into the study?** Record "Yes" if the infant was randomized into the study.
   If No, indicate the reason the infant was not randomized.
   If Yes,
   a. Date of Randomization- Enter the date on which the randomization envelope was opened to enroll the infant into the study. All dates for this study are recorded using the MM/DD/YYYY format.
   b. Time of Randomization- Enter the local time at which the envelope was opened to randomize the infant.
   c. Randomization Number-Enter the randomization Number. This number is recorded on the SUPP02 during the randomization. The randomization numbers are four digit numbers with a different set of numbers, stratified by gestational age, for each group. There will be a group with gestational age from 24 - 25 6/7 weeks and a group with gestational age 26 to 27 6/7 weeks. The groups for each Center will be as follows:

   24 - 25 6/7 weeks = 3001 - 3160
   26 - 27 6/7 weeks = 4001 – 4160

   d. Treatment Assignment:
   Enter 1= Early Extubation and CPAP or 2= Early Surfactant and Ventilation

   e. Oximeter Color Code
   Enter 1= Blue or 2=Orange

   All times for this study are recorded using the 24-hour clock format (00:00 to 23:59).

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

Chapter 8

Delivery Form

8.1 Instructions for completing the Delivery Form (SUPP03)

8.2 Form Section A: Delivery Room Information

1. Date and time of Delivery

a. Date:

Record the date on which child was born (day begins at 00:00, ends at 23:59).

b. Time:

Use a 24-hour clock with midnight coded as 00:00.

2. Was CPAP initiated in the DR? An application of CPAP will be considered the fitting of a mask over the infant's airway without intermittent positive pressure breaths or the placement of nasal prongs.

Record 'Y' if CPAP was initiated in the DR

a. If Yes, time of CPAP initiation

Use the 24-hour clock with midnight coded as 00:00

b. Device: Record Device.

1= Neopuff
2= Ventilator
3=Anesthesia Bag
4= Bubble
9 =Other

If Device is 5, specify the type.

3. Was positive pressure ventilation (PPV) initiated in the DR? PPV is defined as the administration of intermittent positive pressure breaths using either a mask or endotracheal tube.

4. Was positive end-expiratory pressure (PEEP) used in the DR?

Record 'Y' if PEEP was used in the DR

a. Maximum PEEP:

Record the maximum PEEP level as cm/H_20

5. Was intubation attempted in the DR?

a. **If Yes, was the intubation successful?**

Code Yes if the intubation was successful.

6. Indication for intubation

Record the indication for intubation;

1= Surfactant administration

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

2= Resuscitation
3 = Other (specify)
4 = As required by randomization assignment
Code 4 will be used to indicate that the infant was intubated because of the protocol assignment of Early Surfactant.

If for (2) Resuscitation
a. Low HR? Record Yes if the infant was resuscitated because of low HR.
b. Poor color? Record Yes if the infant was resuscitated because of poor color.
c. Apnea? Record Yes if the infant was resuscitated because of apnea.
d. Other? Record Yes if the infant was resuscitated for any other reason and specify the reason.
If for (3) Other, specify the indication for intubation.

7. Did the infant receive surfactant in the delivery room?
Record 'Y' if the infant received surfactant in the DR.
If Yes, Date and time of surfactant administration
a. Date: Record the date of surfactant administration using the mm/dd/yyyy format.
b. Time: Record the time of surfactant administration using the 24-hour clock with midnight coded as 00:00.

c. Type: Record the type of surfactant given
1= Infasurf
2= Curosurf
3= Survanta
4= Exosurf
5= Other, specify the type.

8. Was active resuscitation required? Record 'Y' if active resuscitation was required which would include bag and mask ventilation and/or intubation in the delivery room.
If Yes,
a. Chest compressions?
Record 'Y' for external pressure over central chest to contract heart.
If Yes,
1. Duration: Record the duration of chest compressions in minutes.
b. Epinephrine?
Record 'Y' if Epinephrine was provided to the infant at the time of birth irrespective of route (intratracheal or intravenous)
1. Number of doses: Record the number of doses the infant received.

9. Status following resuscitation:
Record 'the status of the infant at delivery.
1= Admitted to the NICU for further care
2= Infant died

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

Chapter 9

Admission to NICU Form

9.1 Instructions for completing the Admission to NICU Form (SUPP04)

The purpose of this form is to determine if the study interventions are applied as per the protocol

9.2 Section A. NICU Admission

1. Date and time of admission to the NICU:

a. Date: Record the date the infant was admitted to the NICU. Day begins at 00:00, ends at 23.59

b. Time: Record the time the infant was admitted to the NICU using the 24-hour clock with midnight coded as 00:00.

2. Respiratory support on admission to the NICU:

Record the respiratory support as:
1= HVF
2= CV
3= Nasal SIMV
4= CPAP
5= NC
6= Hood
7= No Support

3. SaO_2

Record the infant's SaO_2 on admission to the NICU.

4. FIO_2

Record the infant's FiO_2 on admission to the NICU.

5. Was a blood gas done after admission to the NICU?

If Yes, Record the first blood gas obtained following the NICU admission:

a. Date: Record the date the infant was admitted to the NICU. Day begins at 00:00, ends at 23.59

b. Time: Record the time the infant was admitted to the NICU using the 24-hour clock with midnight coded as 00:00

c. Source: Record the source of the first blood gas
1= Arterial
2=Venous
3= Capillary

Record the results of the first blood gas.

d. pH:

e. pCO_2:

f. pO_2:

g. FiO_2:

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

6. Date and time the study oximeter was placed on this infant.
Record the date and time:

a. Date: Record the date the infant was admitted to the NICU. Day begins at 00:00, ends at 23.59
b. Time: Record the time the infant was admitted to the NICU using the 24-hour clock with midnight coded as 00:00
c. Serial Number: Record the serial number that is pre-labeled on the oximeter.

9.3 Section B. NICU Procedures

1. Was the infant intubated for the first time after admission to the NICU within the first 14 days?

If Yes, Record the date and time:

a. Date: Record the date the infant was admitted to the NICU. Day begins at 00:00, ends at 23.59
b. Time: Record the time the infant was admitted to the NICU using the 24-hour clock with midnight coded as 00:00

c. Indication for intubation:

1. Surfactant?
2. FIO_2 > .50 to maintain $Sa0_2$ ≥88%?
3. $PaC0_2$ >65 on single blood gas?
4. Apnea requiring bag and mask ventilation?
5. If No to all above, state reason:

Record reason:
1= Hemodynamic instability
2= Clinical shock/sepsis
3= Other reason, If other, specify other reason.

2. Was a blood gas done within 30 minutes prior to intubation?

Note: Complete this question only if question B.1 = YES

If Yes, Record the date and time:

a. Date: Record the date the infant was admitted to the NICU. Day begins at 00:00, ends at 23.59
b. Time: Record the time the infant was admitted to the NICU using the 24-hour clock with midnight coded as 00:00
c. Source: Record the source of the first blood gas
1= Arterial
2=Venous
3= Capillary

Record the results of the first blood gas.
d. pH:
e. $pC0_2$:
f. pO_2:
g. FiO_2:

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

3. Was Surfactant given in the NICU?
If Yes, Record the following for each dose: If more than 4 doses given see form SUPP04a

a. Date: Record the date the infant received the first dose of surfactant in the NICU and for the first 14 days. Day begins at 00:00, ends at 23:59
b. Time: Record the time the infant received the first dose of surfactant in the NICU using using the 24-hour clock with midnight coded as 00:00
c. Type: Record the type:
   1= Infasurf
   2= Curosurf
   3= Survanta
   4= Exosurf
   5 = Other, If other, specify type.

Note: If more than 4 doses were given, record each additional dose on form Supp04a.

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

Chapter 10

Safety Monitoring Form
SUPP05 SUPP05A SUPP05B

10.1 Introduction

The SUPP05 form will collect respiratory data for Study Days 1-14 to monitor progress of the infant. The SUPP05A will monitor the incidence of intubation/extubations for each Study Day 1-14.

10.2 Instructions for completing the Safety Monitoring Form (SUPP05)

The purpose of this form is to record daily respiratory information **for each study day while infant is in the network hospital**. This form should be completed starting with DOL1 (study day 1) through DOL 14 (study day 14) and information recorded will be based on the calendar day and 24 hour clock.

1. Study Day: Enter the day this form is being completed.

2. Date: Enter the date that corresponds to the Study Day.

3. FiO2 Information: Record FiO2 and respiratory support closest to the Scheduled Time.

a. Scheduled Time
The scheduled time is given on the first column of the table. A scheduled time is assigned for a 24 hour period. The scheduled times are labeled as:

1. Scheduled Time: 02:00
2. Scheduled Time: 04:00
3. Scheduled Time: 06:00
4. Scheduled Time: 08:00
5. Scheduled Time: 10:00
6. Scheduled Time: 12:00
7. Scheduled Time: 14:00
8. Scheduled Time: 16:00
9. Scheduled Time: 18:00
10. Scheduled Time: 20:00
11. Scheduled Time: 22:00
12. Scheduled Time: 23:59

b. Time Measured
Record the actual time that the FiO2 was obtained based on a 24-hour clock. This time should be recorded adjacent to the closed Scheduled Time listed in column "a".

f. FiO_2
Record the FiO_2 at the scheduled time points. When a blood gas is obtained during a scheduled time, record the FiO2 corresponding to that blood gas. This will be the same FiO2 recorded in question 4 (f) and will supersede the blood gas obtained q2hrs.

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

h. Mode of Support
Record the respiratory support as:
1 = HFV
2 = CV
3 = Nasal SIMV
4 = CPAP
5 = NC
6 = Hood
7 = No Support
8 = Infant temporarily out of unit
9 = No Support all day and off Study oximeter

i. If Mode = 5 record Flow Rate
Record the flow rate for infants on nasal cannula

j. If Mode of Support =4 (CPAP), type used:
Record the type of CPAP
2= Ventilator
4= Bubble
6= Flow Driver
9 = Other

4. Blood Gas Information: Record results of blood gas analyses done at 3 daily time points closest to 08:00, 16:00, and 23:59 if available.

a. Scheduled Time
The scheduled time is given on the first column of the table. A scheduled time is assigned for a 24 hour period. The scheduled times are labeled as:

1. Scheduled Time: 08:00
2. Scheduled Time: 16:00
3. Scheduled Time: 23:59

b. Time Measured
For blood gas information record the actual time that the blood samples were collected based on a 24-hour clock. This time should be closest to 08:00, 16:00 or 23:59. If one blood gas qualifies as closest to two scheduled times (e.g. 23:59 and 8:00 the next day) enter the blood gas on the earlier of the selected times and enter ** : ** for the later one.

c. pH
Record the acid base status of the blood.
d. $C0_2$
e. PO_2:
f. FiO_2
Record the **FiO_2** corresponding to the blood gas at the scheduled time points. Record this FiO2 in question 3 "f" at the appropriate time measured.

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

g. Source:
Record the source of the blood gas
1= Arterial
2= Venous
3= Capillary

h. Mode of Support
Record the respiratory support as:
1 = HFV
2= CV
3 = Nasal SIMV
4 = CPAP
5 = NC
6 = Hood
7 = No Support
8 = Infant temporarily out of unit
9 = No Support all day and off Study oximeter

i. If Mode = 5 record Flow Rate
Record the flow rate for infants on nasal cannula

j. If Mode of Support =4 (CPAP), type used:
Record the type of CPAP
2= Ventilator
4= Bubble
6= Flow Driver
9 = Other

5. Oximeter Alarm Check.
The alarm checks should be recorded every 6 hours. Each center can use a 6 hours schedule that best fits their NICU's routine. The purpose of the oximeter alarm checks is to verify that alarms are being used and will be a measure of compliance of the protocol (i.e. to verify that the alarm limits are in place). The time points (q6h) can vary at each center but attempts should be made to use a 6 hour schedule. That is why the times are left open to fit each centers routine. Regardless whether the alarms are locked or not, we want to document that caregivers are noting alarm limits. We hope that this will increase awareness of the need for the limits to remain in place. And if changes are needed to the alarm limits, they should be made according to the study guideline

6. Was the infant intubated or extubated on this day?
If Yes, Complete the SUPP05A

10.3 Intubated/Extubated Information on the SUPP05A Form (For NICU ONLY)

This form should be completed if Question 6 on the SUPP05 is coded **"Yes".** If more than one intubation/extubation occurs complete a new report for each event. Record the intubation/extubation history if needed for each Study Day 1- 14. If the infant did not have an intubation/extubation on a study day, do not complete SUPP05A.

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

Report Number
Consecutively number each event as reported on the SUPP05a form.

1. Study Day
Record the study day (1 – 14) in which the intubation/extubation occurred in MM/DD/YYYY format

2. Date
Record the date in which the intubation/extubation occurred.

3 Was the infant intubated on this day?
Record Yes if the infant was intubated on this day.
If Yes,
a. Record the time of intubation:
b. Record the following information prior to intubation:

1. Were blood gases obtained within 6 hours prior to the event?
Code 'Yes' if the blood gas that, in the opinion of the investigator, is most associated with the event was obtained within 6 hours prior to the event. Record 'No' if there is no blood gas measurement associated with this event or was obtained >6 hours prior to the event.

Example: If an infant is stable and then requires emergent intubation and a blood gas was not obtained, code 'No'.

If Yes, record:
a. pH
b. PCO_2

2. FiO_2
3. Saturation
4. Apnea? Record Yes if the infant had Apnea on this day.
5. Sepsis/R/O Sepsis? Record Yes if the infant had Sepsis/R./O Sepsis on this day.
6. Hemodynamic instability? Record Yes if the infant had hemodynamic instability on this day.
7. Clinically significant PDA? Record Yes if the infant had clinically significant PDA on this day.
8. Other (specify). Record Yes if the infant had other conditions this day. Specify these.

4. Was the infant extubated on this day?
Record Yes if the infant was extubated on this day.

If Yes,
a. Record the time of intubation:

b. Type of extubation:
1= Planned
2= Accidental

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

c. Record the following prior to extubation

1. Were blood gases obtained within 6 hours prior to the event?
Code 'Yes' if the blood gas that, in the opinion of the investigator, is most associated with the event was obtained within 6 hours prior to the event. Record 'No' if there is no blood gas measurement associated with this event or was obtained >6 hours prior to the event.

Example: If an infant is stable and then requires emergent intubation and a blood gas was not obtained, code 'No'.

If Yes, record:
a. pH
b. PCO_2

2. FiO_2
3. Saturation

10.4 Instructions for completing the Replacement Oximeter Form (SUPP05B)

The purpose of this form is to record each time a study oximeter is replaced on an infant from study initiation to 36 weeks or status (whichever comes first).

a. Episode Number
Consecutively record each oximeter replacement as indicated by the preprinted episode number

b. Date Oximeter Replaced
Record the date the replacement oximeter was first utilized for this infant in MM/DD/YYYY format

c. Time Oximeter Replaced
Record the time the replacement oximeter was first utilized for this infant based on a 24-hour clock

d. Replacement Oximeter Serial Number
Record the six digit serial number of the replacement oximeter used.

e. Replacement Oximeter Color Code
Record the color code assigned to the replacement oximeter.
1= Blue
2= Orange

Note: Color codes are assigned by RTI when study oximeters are sent to participating Centers. Please contact RTI study coordinator at 919-485-7750, zaterka@rti.org to verify color code assignments if in question.

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

Chapter 11

Protocol Deviation Form

11. 1 Introduction

The purpose of the protocol deviation form is to facilitate the accurate documentation of the facts and circumstances surrounding a deviation from or violation of the protocol. This form should be completed for all randomized patients whenever a protocol deviation is encountered by study personnel. ***This form will be keyed at the sites.***

All protocol violations will be reviewed by the center PI who will discuss each protocol violation with the involved clinicians and provide a written summary including steps taken to avoid future violations.

11.2 Instructions for completing the Protocol Violation Report (SUPP06)

1. Date of Protocol Deviation:
Record the date the deviation was first encountered using the mm/dd/yyyy format.

2. Type of Protocol Deviation:
Record the type of protocol deviation:
1= Infant intubated without meeting study criteria
2= CPAP not initiated if required by the protocol
3= Surfactant not given in the first hour
4= Mechanical ventilation initiated for other than study criteria
5= NSIMV initiated in infant not previously intubated
6= Extubation (exclude unplanned extubation) for other than study criteria
7= Failure to extubate CPAP infant if all criteria are met
8= Infant received incorrect treatment assignment
If protocol deviation =8, indicate the treatment arm.
1= Ventilator strategy
2= Oximetry strategy
3= Both
9= Oximeter not started within 2 hours.
11= Infant randomized to incorrect gestational age group
12= Postnatal steroids given for BPD/CLD within 21 days of life
99= Other: Specify type of protocol deviation

3. Circumstances of the protocol deviation/violation:
Briefly describe the circumstances that led to the protocol deviation/violation. In particular, if there were medical reasons for deviating from/violating the protocol, describe them.

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

4. Additional comments:
Record any additional comments or information here such as steps taken to prevent recurrence of the deviation/violation.

5. Name of the person reporting the deviation/violation:
The name of the individual making the report should be recorded here.

6. Date Protocol Deviation Form is completed:
Record the date this form was completed.

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

Chapter 12

Reintubation Form

12.1 Introduction

The purpose of this form is to document all reintubations after day 14 for the duration of hospital stay.

12.1.1 Instructions for completing the Reintubation Form (SUPP07)

Complete this form for every reintubation and subsequent extubation after 14 days for the duration of hospital stay until status.

a. Event
Enter event code as:
1= Reintubation
2= Extubation

b. Date of event:
Enter the date of the event using the mm/dd/yyyy format.

c. Reasons for reintubation:
1 = Apnea / hypoventilation
2 = Increased respiratory effort
3 = Sepsis/Possible sepsis
4 = Atelectasis
5 = Elective procedures
6 = Upper airway abnormality
7= Self/Unplanned
8 = Other reasons

Record the code(s) corresponding to the reason(s) for the reintubation as recorded from the chart. There may be a maximum of three reasons recorded.

If code =8 other reasons, specify reason for reintubation if it is not listed.

d. Record FiO_2 and PCO_2 if available:
Record the FiO_2 and PCO_2, if within 6 hours prior to the event.

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

Chapter 13

Serious Adverse Experience

13.1 Introduction

Serious and unanticipated adverse events may be anticipated in this vulnerable population. **Data on the following potential adverse events that may be related to the study maneuver will be recorded and evaluated as part of continuous safety monitoring during the trial by RTI:**

13.2 Adverse Event Form (SUPP08)

Complete this for any randomized infant who experienced one or more of the following adverse events during the initial 14 days of life Record a consecutive Report Number in the header for each form submitted. This form should be completed and keyed at the sites as soon as possible.

1. Air leak

a. Pnemothorax
Record 'Y' if pneumothorax is documented in the infant's chart. Pneumothorax is a collection of air in the pleural space where a lucency is identified in the pleural space with displacement of the lung away from the chest wall. Do not include a pneumothorax resulting from a thoracotomy during surgery (e.g. PDA ligation). Otherwise code 'N'

b. Pulmonary Interstitial Emphysema (PIE)
Record 'Y' if pulmonary interstitial emphysema (PIE) is documented in a radiographic report in the infant's chart. PIE is a radiographic and pathologic diagnosis made when air ruptures from alveoli or small airways into the perivascular tissues of the lung. This diagnosis will only be documented if from the radiographic reports. Do not include PIE documented in patient notes unless there is radiographic documentation to support this diagnosis. Otherwise code 'N'

c. Pneumopericardium
Record 'Y' if pneumopericardium is documented in the infant's chart. This documentation may be found in a radiographic report, echocardiogram report or patient progress notes. Pneumopericardium is an extrapulmonary collection of air in which the air completely surrounds the heart, including its inferior border. Otherwise code 'N'.

If coding 'Y' to question 1.a, b or c above, code most proximate mode of ventilatory support for each occurrence as follows:

1 = HFV
2= CV

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

3 = Nasal SIMV
4 = CPAP
5= NC
6= Hood
7= No Support
8 = Infant temporarily out of unit
9= No Support all day and off Study oximeter

Record 'Date of Onset" and 'Attribution to SUPPORT study' for each occurrence.

2. The need for chest compressions, and/or epinephrine in the delivery room
3. The occurrence of severe IVH (Grades 3-4, Papile)[i]
4. Pulmonary Hemorrhage
5. Nasal breakdown requiring discontinuation of nasal prongs
6. Death
7. Other (specify) Specify if there were other adverse events.

13.3 Definition of a Serious Adverse Experience

1. An adverse experience is any undesirable experience associated with the use of a medical product in a patient.
2. Associated means that there is a reasonable possibility that the experience may have been caused by the drug.
3. Serious adverse experience means any experience that suggests a significant hazard, contraindication, side effect or precaution.
4. With respect to human clinical experience, a serious adverse drug experience includes any experience that is fatal or life threatening, is permanently disabling, requires inpatient hospitalization, or is a congenital anomaly, cancer, or overdose.

Death
Submit a report if the patient's death is suspected as being a direct outcome of the adverse event.

Life Threatening
Submit a report if the patient was at substantial risk of dying at the time of the adverse event or it is suspected that the use or continued use of the product would result in the patient's death
.
Examples are: pacemaker failure; gastrointestinal hemorrhage; bone marrow suppression; infusion pump failure which permits uncontrolled free flow, resulting in excessive drug dosing.

Inpatient Hospitalization (initial or prolonged)
Submit a report if admission to the hospital or prolongation of a hospital stay results because of an adverse event. Examples are: anaphylaxis, pseudomembranous colitis, or bleeding causing or prolonging hospitalization.

Disability
Submit a report if the adverse event resulted in a significant, persistent, or permanent change, impairment, damage or disruption in the patient's body function/structure, physical activities or

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

quality of life. Examples are: cerebrovascular accident due to drug-induced hypercoagulability, toxicity, peripheral neuropathy.

Requires Intervention to Prevent Permanent Impairment or Damage
Submit a report if you suspect that the use of a medical product may result in a condition which required medical or surgical intervention to preclude permanent impairment or damage to a patient. Examples are: acetaminophen overdose-induced hepatotoxicity requiring treatment with acetylcysteine to prevent permanent damage, burns from radiation equipment requiring drug therapy, breakage of a screw requiring replacement of hardware to prevent malunion of a fractured long bone.

Adverse experiences will be reviewed by the Data Safety and Monitoring Committee.

13.4 Completing the MedWatch Form (SUPPO8A)

In the event of a patient death or unexpected serious adverse event not documented in the case report form, the PI must be notified right away. The attending physician should write a detailed description of the clinical events to include all the elements of the FDA 3500A (MedWatch) form (see Appendix **A**), the patient's date of birth, Network number, and whether the treatment was stopped. The description should be faxed to Dr. Rosemary Higgins at NICHD (301 496-3790) with a copy sent to Kris Zaterka-Baxter at the DCC (919 485-7762).

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

Chapter 14

Outcome Status Form

14.1 Introduction

The purpose of this form is to document the final outcome status of the infant.

14.1.1 Instructions for completing the Outcome Status Form (SUPP09)

This form is to be completed when the infant is discharged to home, transferred, if hospitalized at 120 days, death or withdrawn (which ever comes first).

14.1.2 Section A - Infant Outcome

1. **Status of infant at time of completion of form:**

   - **Discharged to home**
     Record '1' if infant was discharged to home without returning in 7 days.
   - **Still in hospital at 120 days**
     Record '2' if infant is still in the hospital at 120 days.
   - **Transferred to another hospital**
     Record '3' if infant was transferred to another hospital without returning in 7 days.
   - **Transferred to chronic care facility**
     Record '4' if infant was transferred to a chronic care facility without returning in 7 days.
   - **Death**
     Record '5' if the infant died.
   - **Withdrawn form study**
     Record '6' if the infant was withdrawn from study by a parent, legal guardian or physician; Use the F5 key to comment on circumstances of withdrawal if known (i.e., parent or physician withdrawal)

2. **Date of status:**
   Give date at status.

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

14.1.3 Section B - Neurologic

1. Did the infant have a head ultrasound between 4 - 21 days of age?
Code Yes if an ultrasound was performed between 4 - 21 days. Code No otherwise. If a cranial ultrasound is not done for standard of care, the study requires that at least one HUS be completed during this window.

If Yes,
a. Date of ultrasound:
Record the date of the head ultrasound obtained using the mm/dd/yyyy format. **Note**: If more than one head ultrasound is done between 4 - 21 days of age, record the date of the most severe.

If Yes,
b. Time of ultrasound:
Enter the time of the head ultrasound obtained using the 24 hour clock format (00:00-23:59).

c. Infarct?
Code Yes if an infarct was diagnosed by the local sonographer. Code No otherwise.

d. IVH?
Code Yes if evidence of intraventricular hemorrhage was observed on the head ultrasound. Code No otherwise.

If Yes,
1) IVH Grade:
Enter the severity of the intraventricular hemorrhage observed on the head ultrasound using the Papile scale:

Grade I: Code 1 if the echodensity/hemorrhage is confined to the germinal matrix/subependymal area.

Grade II: Code 2 if there is an echodensity/hemorrhage in the lateral ventricle(s) without distention.

Grade III: Code 3 if there is an echodensity/hemorrhage in the lateral ventricle(s) with distention.

Grade IV: Code 4 if there is an echodense lesion in the parenchyma.

e. PVL?
Code Yes if periventricular leukomalacia (increased echogenicity or cysts in periventricular region) was observed on the head ultrasound. Code No otherwise.

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

14.1.4 Section C – Ophthalmology

1. Was an exam performed for Retinopathy of Prematurity (ROP)?
Review the medical record to determine if an examination was performed for ROP.
If Yes, complete the **SUPP10 Form** (ROP Outcomes And Tracking Summary).
If No, and the infant survived, complete the **SUPP10** (ROP) form based on subsequent exams (including back-transfer hospital and/or outpatient visits)

14.1.5 Section D – Postnatal Steroid Use

1. Did the infant receive postnatal steroids after the first 21 days of life?
If Yes, record the information on number of courses, start date, stop date, drug administered and total dose administered during the course in mg/kg. If No, the boxes are left blank.
Note: Only steroids given IV or PO are included for the purposes of this study. Inhaled steroids **are not** included.

a. Course:
A course is defined as all of the doses given in a period between an initial, usually high dose, and subsequent tapers. It may include a period when drug is given every other day. For the purposes of this study, a course is defined as ended when 72 hours passes without a steroid dose. If 72.5 hours passes and the infant receives another series of doses of the same or a different steroid, this is considered to be a second course.

b-c. Start and Stop Date:
The first and last doses given in a single course. RTI will use these dates to define the duration of exposure in days.

d. Drug:
Record the steroid administered using the following codes:
1= Dexamethasone
2= Betamethasone
3= Hydrocortisone
4= Prednisone
5= Other (Specify the other drug that was given)

e. Total Dose:
Calculate the total dose given in the course expressed as mg/kg. For example, the baby receives a course of dexamethasone beginning at 0.2 mg/kg for 2 days, and subsequent doses given as 0.1 mg/kg given for 2 days, 0.05 mg/kg for 2 days, 0.05 every other day for 2 doses, and then discontinue. The total dose administered to this patient is 0.2+0.2+0.1+0.1+0.05+0.05+0.05+0.05. The total dose administered is 0.8 mg/kg.

If the dose is not expressed in mg/kg in the medical record, the researcher calculates the mg/kg dose using: 1) the weight used in calculating the dose if documented, 2) the weight on the day the order was written to calculate the mg/kg.

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

Chapter 15

ROP Outcomes and Tracking Summary

15.1 Introduction

The purpose of this form is to track and document the acute ROP outcome of each eye. Tracking the course of ROP should begin with the first examination and will generally be much easier if the coordinator attends the examinations and asks the ophthalmologist in person about the categories to be recorded.

Data may be entered in the database from the form after each examination, or may be entered when the infant reaches "acute/final" status. However, monitoring of the examinations and progress will be much more complete and helpful if these are entered after each examination.

15.1.1 Instructions for completing the ROP Outcomes and tracking Summary (SUPP10)

Complete this form for all enrollees in SUPPORT who survive to have their first eye examination. This normally is scheduled at 31 weeks postmenstrual age (but not earlier than 4 weeks after birth).

Record the data for each eye examination until each eye has reached "acute/final" status (see definition below in 15.2). This will sometimes include examinations following discharge home or transfer to another hospital.

1. Date of Exam

If a confirming examination is conducted, each should be separately recorded.

2. Location of Exam

Code 1= inpatient for the primary hospital where the infant has been cared for, including other Units in that same hospital (step down units, pediatric intensive care, surgical care units, etc.)

Code 2=Outpatient for examinations in the outpatient ophthalmology department, private ophthalmologist's office or other outpatient visits. Include infants at a chronic care facility transported to the physician's office for an examination.

Code 3= Transfer Hospital when infants have been back transferred to a referring hospital or regional hospital.

Note: Outpatient and back transfer hospitals can be a common source of infants missing examinations and "slipping through the cracks". Be particularly attentive to ensuring timely repeat examinations in these cases and ensure that the family is aware of the importance and critical timing of the examinations.

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

3. **Lowest zone:** Record the lowest zone that contains vessels that end before crossing out of that zone. This may be zone I (the most immature), zone II (intermediate) or zone III (most mature). The ophthalmologist normally records this on the eye examination form. The most common for SUPPORT infants will be zone II at the early examinations. There may be vessels recorded in:
   - zone I and II (you record zone I)
   - zone I only (you record zone I)
   - zone II only (you record zone II)
   - zone III only (you record zone III)

   Note that by convention, disease is never to be recorded in zones II and III in the same eye. If the two nasal clock-hours are not fully vascularized, by convention, no vessels in that eye are to be recorded in zone III. If they are fully vascularized, the all the rest of that eye's vessels are in zone III.

4. **Highest stage in lowest zone** (not to be used if eye has had surgery)
   Look first at the lowest zone that has vessels ending in it (see previous answer). Then look to see if there is ROP in any of the clock hours of that zone. Choose the highest stage of ROP in that zone to record.

   Examples:
   If the eye has vessels ending in just zone I, but no ROP, the highest stage is zero.

   If the eye has vessels ending in zone I and zone II and the ROP in zone I is stage 2 while the ROP in zone II is stage 3, the highest stage in the lowest zone (I) is stage 2.

   If the eye has vessels ending in zone I, but there is no ROP in zone I, but there is stage 2 and stage 3 ROP in zone II, the answer would be 0=no ROP in the lowest zone.

5. **Highest stage in any zone** (not to be used if eye has had surgery)
   Look at the stage of ROP around the 12 clock-hours of the recorded examination. Choose the highest stage to record. In rank order going from lowest to highest the order is 0, 1, 2, 3, 4a, 4b, 5. The other categories are for less common cases.
   - Code 4 = stage 4a or 4b is a partial retinal detachment
   - Code 5 = stage 5 which is a total retinal detachment
   - Code 6 = Post laser/cyro (do not use stages)
   - Code 9 = Old scars, but no active ROP

6. **"Plus disease"**
   This is recorded by the ophthalmologist as present or not. Sometimes they provide comments like 'borderline plus' or 'possible early plus disease' or 'mild dilation, but not plus disease'. In these cases, do not record 'plus disease' as present. If the ophthalmologist records plus disease by quadrants, two or more quadrants are required to meet criteria for plus disease (i.e. only one quadrant of dilated/tortuous vessels is not sufficient.).

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

7. Threshold (New Type 1 threshold per ETROP)

The ophthalmologist who diagnoses threshold ROP needing surgery will normally state this prominently on the examination form. The criteria for the new threshold are any of the following four findings:

If in zone I: stage 3 ROP, even without plus disease
plus disease with any stage ROP

If in zone II: plus disease with stage 2 ROP
plus disease with stage 3 ROP

There may be times when disease is worse than this, but it should still be recorded as threshold.

There will be some times when the judgment of the retinal surgeon and neonatologist will be not to administer treatment (laser or cryo), even when there is new threshold. Normally infants are then followed extremely closely (every few days repeat examinations).

8. Surgery

For each examination date, record if surgery is performed on that day. (mostly will be no). If surgery was previously performed, but not on the day of that examination, record 0

9. Post-surgical Retinal Detachment after surgery

This at first looks like a repeat of the question asking for stage of ROP, but it is not since it is intended to be used only after surgery has occurred.

10. Final Acute Status Lost to Follow-up at 55 weeks PMA

Complete this question **only** for the final eye exam entered.

Record 'N' if the last examination meets criteria for final acute status reached (see section 15.2 below).

Record 'Y' if the final 'acute' ROP status is permanently missing because the infant is lost-to-follow up. For example, the last exam is not yet mature, or not yet in zone III for the second time in a row, or the baby still has ROP, but had not reached criteria for surgery. All attempts must have been made to capture this data from the follow up exams, and it is coded 'Y' as missing only when there was no final exam done (parents did not bring infant in).

By the time an infant has reached 55 weeks PMA, the eye disease will have reached final status, whether we know about it from an examination or not. That is why we make this determination at this time. If it is later learned that examinations actually were done, the results can be entered on the form with a late correction/edit.

Therefore, if you know the infant is less than 55 weeks PMA and has not had an exam that meets the final/acute criteria, you are still trying to get the family to bring the baby in for exams because it is clinically important and also will give you a primary

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

study outcome. If it is now past 55 weeks, you may give up trying to get them to come in because it's too late to identify disease that could be treated, and the time for the clinical outcome for the study is also past. Late outcomes will be collected at the 18-22 month follow up examination.

Potential merit of later exams: Most likely, they will reassure the infant that the eyes have healed. They may detect an important need for glasses at 6-9 months after birth. If the outcome is retinal detachments, the parents will learn the baby is not going to see and needs to be referred for early intervention. In either event, late exams that show retinal detachments will confirm that once upon a time, the baby did have bad ROP. Late exams that show good outcomes will NOT tell us if they once had ROP that has now regressed (healed).

Note: even in these circumstances where we have given up, the infant will still be tracked down for the 18-22 month follow up visit. At that time they are asked if any eye surgery was done after discharge / status. If yes, what surgery. If it was for ROP, then that will become a final status revision. Also, even if no surgery was done, but the child has experienced vision loss *from ROP*, this would also be a final outcome.

Note that some infants have vision loss that is not from ROP. This is usually "cortical vision loss" and is from brain injury.

11. Final ROP Status determined at 18 Moth Follow Up
Complete this question **only** for the final eye exam entered.

Answer this question as 'N' if the final acute status was already determined before 55 weeks PMA. That is, "no, we did not determine the final outcome based on the 18-22 month exam."

Also, answer this question as 'N' if the final status was not determined by 55 weeks PMA, AND it was not determined at the 18-22 month visit either. This would happen if there were no 18-22 month examination. It would also happen if there were an 18-22 month examination, but the parents report no eye surgery and no other eye exams so we don't know what happened to the ROP.

You can record 'Y' for the final ROP status obtained during the 18-22 month follow up visit only if the parents are now reporting to you eye surgery for ROP that you had not learned about before, or they are telling you about eye exams that you have not learned about before (or else you would have recorded it before). If this is the case, reports from the exam(s) and/or surgery should be obtained to determine what has happened. These data will likely require ophthalmology input to determine if the primary ROP outcome was reached. Examples: A. ROP can be assumed (imputed) to have reached surgical criteria if the infant's subsequent surgery is vitrectomy for retinal detachment, or is an exam under anesthesia with a diagnosis of ROP stage 4A, 4B or stage 5 ROP, or retinal fold crossing the macula. B. ROP may not have met laser/CRYO criteria if the surgery was for strabismus (crossed eye), plugged tear duct, or only examination under anesthesia, for example to rule out glaucoma.

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

15.2 Acute/final Status

An eye is 'acute/final" when it reaches one of the following points in time:
These can be a good outcome (favorable) as the ROP heals (regresses), or it can be the primary outcome variable event (unfavorable).

Favorable

- Vessel growth if mature to the ora serrata in all clock hours
- Vessels in zone III for two sequential eye examinations (i.e. two examinations in a row)

Unfavorable

- type I threshold ROP
- Laser (or cryo or both) surgery for acute ROP
- retinal detachment stage 5 retinal detachment stage 4b

Other

- Infant dies.

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

Chapter 16

Respiratory Support after 14 Days

16.1 Introduction

The purpose of this form is to document any respiratory support the infant receives after day 14.

16.1.1 Instructions for completing the Respiratory Support Form after 14 Days (SUPP11)

This form is to be completed daily from study day 15 through 36 weeks or status, whichever comes first.

Record the following information four times for each day. **Note**: the scheduled time points for each day are collected down each column

- **Date**
  Record the date corresponding to the Study day
- **Scheduled Time:**
  Record a - d for each study day for the scheduled time points 06:00, 12:00, 18:00, 23:59.
- **Highest Level of Support**
  Record the highest level of support the infant is in on at the scheduled time points during this **STUDY** day.
  Enter: 1= HFV, 2=CV, 3= Nasal SIMV, 4= CPAP, 5= NC, 6= Hood,
  7= No Support, 8= Infant temporarily out of unit 9= No Support all day and off the study oximeter*.

  * Code 9 should be recorded in the 0600 time period for each day the infant is in no support and is not on the study oximeter. Oxygen (b), flow rate (c), and oximeter alarm check (d) are not required for this time point. No further data are required for the following time points on this day.

- **Oxygen -Yes/No**
  Record "Yes" if the infant was on oxygen at the scheduled time point during the day. Disregard any temporary increases in FiO_2 for desaturation episodes, apnea, bradycardia or procedures where the infant returns to his/her previous FiO_2 in a reasonable amount of time (≤ 30 minutes). Record "No" if the infant is not in oxygen on this day.
- **Flow rate (Nasal Cannula only)**
  Record the highest flow rate the infant was on at the scheduled time during the study day. Disregard any temporary increases in flow for desaturation episodes, apnea, bradycardia or procedures where the infant returns to his/her previous flow rate in a reasonable amount of time (≤ 30 minutes)***Flow rate should be recorded **only** if the

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

infant was on a nasal cannula that day. For purposes of recording, Vapotherm is considered a cannula.

- **Oximeter Alarm Check**
  Record the time the oximeter alarm check was done.
  The purpose of the oximeter alarm checks is to verify that alarms are being used and will be a measure of compliance of the protocol (i.e. to verify that the alarm limits are in place). The time points (q6h) can vary at each center but attempts should be made to use a 6 hour schedule. That is why the times are left open to fit each centers routine. Regardless whether the alarms are locked or not, we want to document that caregivers are noting alarm limits. We hope that this will increase awareness of the need for the limits to remain in place. And if changes are needed to the alarm limits, they should be made according to the study guideline

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

Chapter 17

OXIMETER SETUP

17.1 Oximeter Setup – Masimo Radical

Review the following EACH TIME the oximeter is placed on a baby.

17.1.1 Power

If possible, units should remain plugged in between uses. Where this is not possible the oximeter should be plugged in as soon as possible after randomization.

17.1.2 Initial Settings – [Radical Manual pp. 30-42]

Date – Check to see that the date and time are correct. This must be done prior to gathering data. **Changing the date or time after data collection has started will erase the memory!**

Sensitivity – Set to Normal Mode
Averaging Time – Set to 16 seconds
Alarm Limits – Sat: Suggested between 85 and 95.
Audible Delay – 10 seconds
Trend Period – [43-45] - 10 Seconds **Note: Changing this setting during a recording will erase all data !!**

17.1.3 Help – If you can not find these settings using your oximeter manual, or if you have any problems with the Masimo masked oximeters used in the SUPPORT study, please contact:

1. The local Masimo Clinical Specialist who did the inservicing for your center
   Please identify yourself as one of the SUPPORT centers, with questions about a masked oximeter.

   and/or

2. Masimo Technical Support at 800-326-4890, option 2. tech@Masimo.com
   Please identify yourself as one of the SUPPORT centers, with questions about a masked oximeter. The techs are aware of SUPPORT and the masked oximeters.

   and/or

3. Dr Maribeth Sayre, Director of Medical Affairs for Masimo, and the Masimo liaison for the SUPPORT study. Her contact information is: msayre@Masimo.com
   cell phone 925-337-(b) [redacted]

If a masked oximeter is malfunctioning, it must be sent back to Masimo headquarters. First, a RMA # (Return Material Authorization number) is needed. A copy of the form **is**

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

contained in Appendix E. . Please identify the facility as one of the SUPPORT centers, and the product as a masked Radical handheld or docking station.

If there are questions relating to alarm parameters, they should be referred to Wade Rich.

PLEASE COPY DR. MARIBETH SAYRE ON ALL EMAILS RELATED TO THE MASKED OXIMETERS.

17.2 Downloading Data

17.2.1 Software

The software used to download the data is called TExtract. If you have not gotten a copy, it is available by email from wrich@ucsd.edu or it can be downloaded to your Network computer by RTI.

Using TExtract
A powerpoint presentation showing how to use TExtract is included in the manual as Appendix D.

17.2.2 Cable

Data may be downloaded from the oximeter to a laptop using either a serial cable or a USB-to-Serial cable. A picture of a USB-Serial cable is included in the power-point presentation that was sent out to all the sites.

17.2.3 Preparing Masimo for Download

- Turn Oximeter on.
- Output should be Binary
- Select button
- Use arrow key to highlight "Output".
- Select button.
- Enter the Serial Menu by selecting the button.
- Use arrow key to select "Binary".
- Select ☑ button.
- Select ☒ button twice.

When to Download
Downloads should be done every 2 weeks, or earlier if a child reaches a study milestone (e.g. Off oxygen for 72 hrs, death, discharge, or 36 weeks PCA)

17.2.4 After the download:

Be sure to clear the memory of the Masimo after you have downloaded the data. Otherwise you will send RTI data which they already have along with the new data the next time you download. Clearing the memory is done as follows:

From the main screen when the Masimo is first turned on:
Select the → button.
Select the button.

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

Select the button twice.
Select the icon.
Select the ☑ icon and the data will be dumped.

17.2.5 Uploading Data to Network Computer

Data can be transferred from the laptop to the network computer by way of a floppy disk or a USB Memory Stick. The USB device is preferable because it will hold many studies instead of just one.

To upload this data to your Network computer the USB stick must be put into the USB port on the computer. This is often in the back. A USB extension cable will help make this easier, as one end can just be placed on the desk for easy reach.

The SUPPORT data entry software program from RTI will take you through the process of uploading. The information regarding how to label the files is included in the TExtract Power point appendix D to this manual.

17.2.6 Masimo Technical Issues

It is recommended that the Radical Handheld be docked to the docking station and attached to an AC power source when it is not in use to ensure that the battery remains fully charged. All batteries lose capacity with age. When battery run time is significantly reduced, it is advisable to completely discharge and fully recharge the battery pack. Masimo does not give a recommended TIME FRAME for performing a discharge cycle since every environment is different.

17.2.7 How to Deep-Discharge the Radical Battery

The discharge cycle will take approximately 16 hours to complete for the handheld battery. The Docking Station battery will take approximately 30 hours to complete. A message will appear in the service screen when the discharge cycle is complete. The batteries will be fully charged after completion of the cycle.

Note: *In order for the discharge cycle to be properly completed, the Handheld must be docked to a Docking Station and supplied with AC power throughout the cycle.*

Warning: WHEN DEEP-DISCHARGING THE HANDHELD OR DOCKING STATION BATTERY, MAKE SURE THAT THE DEVICE HAS BEEN REMOVED FROM SERVICE UNTIL FULL BATTERY CAPABILITY CAN BE RESTORED.

1. Press the three page button to access the main menu screen
2. Highlight the Service menu and press the single page button
3. Enter password 2 – 3 – 1
4. Press single page button
5. Confirm by pressing the checkmark
6. Wait until message of "Discharge Cycle is Complete"

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

17.2.8 Defective Equipment

If you need to return defective Masimo equipment, please contact Technical Support at Masimo 1-800-326-4890 for a Return Merchandise Authorization #.
You will need the device serial # when you call.

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

APPENDIX B

SAMPLE CONSENT FORM

University of California, San Diego
Consent to Act as a Research Subject

The Surfactant Positive Airway Pressure and Pulse Oximetry Trial in Extremely Low Birth Weight Infants

The SUPPORT Trial of the NICHD Neonatal Research Network

Neil Finer, MD, his associates, and the National Institutes for Child Health and Human Development (NICHD) Neonatal Research Network are conducting a research study to find out more about treatment with CPAP (positive pressure applied with a face mask to help keep the lungs inflated) and learn the appropriate levels of oxygen saturation (oxygen levels in the blood) in premature babies. You are being asked to allow your child to be in the study because there is a possibility he/she will be born between 16 and 12 weeks early (24-28 weeks gestational age).

The purposes of this trial are the following:
1) To compare infants who receive delivery room CPAP and who have strict guidelines for having a breathing tube placed with infants who have the tube placed and surfactant (a liquid which helps babies with immature lungs breath easier by helping keep their lungs from collapsing) given in the delivery room.
2) To compare low range (85-89%) oxygen saturation levels with high range (91-95%) levels to determine if a lower range results in decreased ROP (Retinopathy of Prematurity, an eye disease that may result in impairment of vision or even blindness, which may be caused by excessive levels of oxygen.)

Duration of the Study: We expect to include about 1300 babies in the study from all the NICHD Neonatal Research Network hospitals over a two year period.

The use of CPAP and Intubation/Surfactant are both treatments currently used in the delivery room at UCSD. The decision as to which to use is currently made by the physician attending the delivery.

The oxygen level currently used in the NICU at UCSD is between 85% and 95%. Both treatment groups (85-89% and 91-95%) fall within that range. The study will attempt to keep babies in one of these two smaller ranges.

If you agree to allow your child to be in this study, the following will happen to your child:
Prior to delivery, and after your permission, your baby will be randomized (chosen by chance like the flip of a coin) to one of two lung treatment strategies. The treatments are as follows:
1) CPAP in the delivery room immediately after birth and continuing in the NICU, or
2) The placement of a tube in his/her trachea (windpipe) in the delivery room followed by surfactant administration and ventilation (breathing for the baby using a machine).

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

In addition to being randomly assigned to one of the two groups described above, your baby will be randomized to a High reading or Low reading oximeter (a monitor that displays how much oxygen is in the blood). The oximeters (oxygen monitors) used in this trial are FDA approved oximeters which have been modified for research purposes. This modification makes the monitors show a value which is either slightly higher or slightly lower than the true oxygen level when values are between 85 and 95%. Outside those ranges, the oximeter works the same as the standard of care device.

Which group your baby is randomized to will not be known to the nurse taking care of your baby, or his/her physician. Only the study coordinator will know which group your baby is in. Within the range of oxygen which we normally keep babies in, your baby will either be on the high end of normal or the low end of normal. He/she will remain on this device until he/she reaches 36 weeks adjusted age. (e. g. 24 wks gestation plus 12 weeks of age = 36 weeks adjusted age). Other care will be conducted as normal during his/her participation in the study. Your baby will be followed in our Infant Follow-up clinic at 6 and 12 months as standard of care for small babies. At 18-22 months corrected age your baby will receive, at no charge to you, a complete exam of their muscles, nerves, and mental and coordinated movement skills.

Participation in this study may involve some added risks or discomforts. Because all of the treatments proposed in this study are standard of care, there is no predictable increase in risk for your baby. Infants randomized to the CPAP group may, at some point in their care, require intubation and assisted ventilation (methods to help them breathe). If the attending physician deems this necessary, participation in the study will not affect this decision. Some unknown risks may be learned during the study. If these occur, you will be informed by the study personnel. The only other risk of this study is the risk to confidentiality. Every effort will be made to keep your child's medical record confidential. There will be no name or other patient identification in any study report that may be published after the study is completed. Measures taken to protect you and your baby's identity are described in the confidentiality section of this document.

There may be benefits to your child directly, including a possible decrease in chronic lung disease (need for extra oxygen near discharge) and/or a decrease in the need for eye surgery as a result of exposure to oxygen. Because we do not know in advance the actual strategies chosen for your child, or which of the treatment strategies is the most effective, it is also possible that your baby will receive no direct benefit. The knowledge learned from this study may help us treat babies in the future. However, as noted above, each of the 4 possible combinations of treatments is considered by some units to represent their desired approach.

If your child is injured as a direct result of participation in this research, the University of California will provide any medical care your child needs to treat those injuries. The University will not provide any other form of compensation to you if your child is injured. You may call the UCSD Human Research Protections Program office at (858) 455-5050 for more information about this, or to inquire about your rights as a research subject, or to report research-related problems.

_____ has explained this study to you and answered your questions. If you have other questions or research-related problems, you may reach Wade Rich, the Study Coordinator, or Renee Bridge, the Research Nurse, at 619-543-6560. You may contact the principal investigator Dr. Neil Finer at 619-543-3794

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

As an alternative to participation in this study you may decide to have your baby's doctor decide which treatment your baby will receive. If you decide not to include your child in this study, none of his/her medical information will be included in the study data. Participation in research is entirely voluntary. You may refuse to participate or withdraw at any time without jeopardy to the medical care your child will receive at this institution of other loss of benefits to which your child is entitled. If you withdraw your child from the study, the attending physician will decide whether to maintain current treatment or change it, based on your child's needs at the time of the decision. Data collection for research purposes will stop at that time.

Clinical information will be collected from your baby's chart by study personnel at UCSD. Information will be labeled with a code number. Coded information will be sent to the NICHD Neonatal Network's Data Collection Center at Research Triangle Institute (RTI) in Research Triangle Park, North Carolina. The study log linking the code number with your baby's identity will be kept under lock and key at UCSD. Information directly identifying your baby will not leave UCSD. Research records will be kept confidential to the extent provided by law.

You may withdraw your child from the study for any reason. In addition, the study doctors may decide to withdraw your child if they feel it is in his/her best interest to do so.

You have received a copy of this consent document to keep and the Experimental Subject's Bill of Rights

You agree to have your child participate.

APPENDIX F

Management of Oxygen Concentrations and Oxygen Saturations in the Infant <28 weeks Gestational Age

OBJECTIVE: To avoid hyperoxia and high/low swings in oxygen saturations in the infant<28 wk GA while receiving supplemental oxygen.

1. Initiate the protocol with the admission of each infant with GA less than 28 weeks at birth.
2. No infant will be subject at any time to repeated swings in the amount of O2 being delivered in response to the saturation readings outside the acceptable range.

STATEMENTS OF PRACTICE:

a. Oxygen is a drug with potentially toxic side effects. Too much can be as damaging as too little. There is no evidence that <28 week infants need saturations in the 95-100% range (while receiving supplemental oxygen) and these levels are potentially dangerous. Alternating episodes of hypoxia and hyperoxia can cause significant alterations in the vascular tone of <28 week infants.

b. Saturation alarms:
   1. Assess the validity of the alarm:
   - Is the pulse wave appropriate?
   - Is there artifact interference?
   - Has the saturation been down low enough for long enough to warrant an increase in FiO2?
   (see Desaturation Management Guidelines)

c. Alarm settings: The alarms should be set at 84% and 96%. Note that Masimo alarms go off at the set value. Thus, these alarm settings are equivalent to alarms commonly set at 85% and 95% on other pulse oximeters. *The alarms should not be disabled at any time while receiving supplemental oxygen*

d. Weaning FiO2 and oxygen saturation levels:
Wean by 2-5% if the saturation is high (>95%).
   - Weaning should be done as fast as necessary to avoid extended periods of hyperoxia. (But not faster than 2-5% at a time)

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

- Avoid weaning in increments >5% at a time; this could result in hypoxia, which would then lead to increasing the FiO2 again.

e. Increasing the FiO2 and saturation levels:
Increase the FiO2 by 2-5% if the saturation is low (<85%).

- When an increase is needed in the FiO2, the person making the change should stay with the infant until the infant has reached a stable saturation level.
- MD/NNP must be notified for any sustained need for an increase in FiO2 greater than 10% from the previously stable FiO2.

f. During and after procedures:
- FiO2 should not be routinely increased prior to a procedure. Individual infants may require modest increases (5-10%) if they tolerate handling poorly. Respond appropriately to the needs of the infant based on the saturations as well as the length and type of procedure.
- Monitor the infant after suctioning the ETT until the baby returns to their previously stable baseline.
- Consider that other settings (rate, PIP, PEEP) may need to be changed for a prolonged procedure.

g. Spontaneous oxygen desaturations:
- Assess both the infant and the ventilator and/or oxygen delivery systems.

h. Apnea:
- Choose the appropriate response based on assessment of the infant; increase respiratory rate, increase the approved parameters, tactile stimulation, or in severe cases manual ventilation.
- If the baby does not return to the previously stable baseline (same FiO2) within 10 minutes, the MD/NNP should be notified.

SUMMARY:

1. Set oxygen saturation monitor alarm limits at 84 and 96%.

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

2. Allow baby to fluctuate within the desired saturation parameters, making small movements up and down on FiO2 as needed.
3. Based on assessment, wean actively by 2-5% for saturations on the high side of parameters.
4. Never increase the FiO2 without first assessing the baby.
5. If the need for increased FiO2 is sustained, the MD/NNP should be notified.
6. Document saturation levels and oxygen requirements clearly (as per unit policy).
7. When altering the oxygen being delivered stay with the infant until the saturations have stabilized within an acceptable range.

I certify that I have read the above practice plan and agree to follow the objectives and statements of practice when caring for infants in the NICU.

Cc: nfiner@ucsd.edu; HigginsR@mail.nih.gov
Subject: RE: NRN Calls- SUPPORT Call

Wally
Nice start to an obviously very important paper. Here are some comments.

1) Methods/enrollmen/treatment: we should point out that the target ranges applied when infants were in O2 and when in room air the upper alarm limit could be raised.
2) Methods, offset of 3%: It would help many readers to know that the offset is the value when the device is reading 90% and that when the device is reading higher values approaching 95% the offset decreases in magnitude. The same concept for when the lower limit is appraoched.
3) Methods: Don't we need to list the downloads of data and processing by RTI with feedback to the centers for time spent with different saturation ranges? This is a very important difference from the literature which everyone sites on the effects of lower oxygen saturation policies without knowledge of where the saturations are.
4) Results/major outcome section: The sentence "The PIs and the NICH D and data center performed a detailed analysis..." is a little unclear regarding the timing of this. If this is left as is, it needs to be clear that not all ROP results are not final since 55 weeks has already occurred.
5) Other major outcomes were comparable? Is BPD (oxygen at 36 wks) different?
6) Median oxygen saturations of each group: can you provide IQR?
7) Results of oxygen saturations: I think you need to present more data to characterize the oxygen saturations while in oxgyen. A table would be helpful for the percent of time with oxgyen saturations >98, 96-98, 93-95, 88-92, 85-87, 80-84 and <80% for each group.
8) Are you going to present age of deaths and assigned causes of death?
9) Table 1: consider including some additional maternal data (chorio/maternal antibiotics, mode of delivery etc)
10) Figure 1: I don't see a number for all the consented mothers who passed thru the gestational age window of the study.

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

11) Discussion: As I am sure you are aware there are limited data on the ability to maintain oxygen saturations within desired ranges. I think there needs to be some mention of this with regards to figure 2 (see Pediatrics 2006;118;1574-1582) and that even very small changes in goal ranges for oxgyen saturation can lead to an increase in oxygen saturation at the low end (J Perinataology 2006;26;337-341)

Hope this helps, tx, AL

The Surfactant Positive Airway Pressure and Pulse Oximetry Trial in Extremely Low Birth Weight Infants – The SUPPORT Trial

The SUPPORT Study Group of the Eunice Kennedy Shriver NICHD Neonatal Research Network

Abstract

Background: The most appropriate initial and ongoing respiratory support for the extremely low birthweight infant (ELBW) has not been established by adequate prospective evidence. The current usual approaches include the early use of continuous positive airway pressure (CPAP) or the early administration of surfactant following endotracheal intubation.

Methods: The SUPPORT study was a randomized multicenter factorial trial that enrolled consented preterm infants of 24 0/7ths weeks to 27 6/7ths weeks by best obstetrical estimate within 2 prospective strata, 24 to 25 6/7ths weeks and 26 to 27 6/7th weeks. Infants were randomized to CPAP initiated in the delivery room and were subsequently treated using a permissive strategy allowing higher PaCO2s and extubation at higher ventilator settings. Infants randomized to surfactant were intubated and received surfactant within 60 min minutes of birth. All infants were also randomized to one of 2 ranges of SpO2 while in the NICU and receiving supplemental oxygen, a low target range of 85% to 89% and a high target range of 91% to 95% using specifically altered blinded oximeters.

Comment [AD1]: Should we rephrase this? Sounds like the infants themselves gave consent!

Results: The study enrolled 1317 infants from January 1 2004 to March 1 2009. There were 565 infants enrolled in the lower gestational age strata, and 751 in the higher strata. In the delivery room, 66% of the CPAP infants received positive pressure ventilation compared with 93% of the surfactant infants, and surfactant was given to 14% of the CPAP versus 51% of the surfactant group (all p<0.001), and 67% of the CPAP infants received surfactant at any time during their hospitalization,. The primary outcome of death or BPD, defined as the need for supplemental oxygen at 36 weeks post conceptional age was 48% versus 54%, ($p < 0.05$, when adjusted for gestational age, center and familial clustering). There was a significantly lower mortality in the 24 to 25 weeks strata for the infants in the Surfactant arm, (24% vs 32%, p=0.03). There were no differences overall for death in the delivery room nor any differences in length of stay, or days of oxygen for survivors, and the need for oxygen at discharge. More CPAP infants were alive and off mechanical ventilation by day 7, (p=0.015). All infants in the Surfactant arm were intubated, compared with only 77% of the CPAP infants requiring intubation during their nursery course, (p<0.001). There were no differences between the groups for air leaks including pneumothoraces.

Comment [AD2]: I would provide the relative risk and 95% CI instead of, or in addition to the p value. Same goes for other CPAP vs surfactant outcome comparisons, both here and in the main text.

Conclusions: The use of early CPAP with a permissive ventilator strategy results in a decrease in death or BPD defined as the need for oxygen at 36 weeks post conceptional age compared with the use of surfactant within 1 hour of birth and a conventional mechanical ventilation approach. There were no increased adverse outcomes in the CPAP group, and the surviving infants will be followed for a complete neurodevelopmental assessment at 18 to 22 months.

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

Early CPAP and the use of a permissive ventilator strategy is an evidence based approach for the initial respiratory support of the ELBW infant.

Introduction:

At the present time, there is no agreement as to the optimal approach to respiratory support for the extremely low birth weight (ELBW) infant following delivery. Positive End Expiratory Pressure (PEEP) has been shown to be of benefit in maintaining functional residual capacity (FRC), and continuous positive airway pressure appears beneficial during cardiopulmonary resuscitation[1]. Gregory et al in 1971 first demonstrated that the use of CPAP started at approximately 5.9 hours (+12.4hrs) for their infants < 1500 gm at birth, improved oxygenation[2] in newborn infants with respiratory distress; these observations were followed by prospective studies that demonstrated improved survival in premature infants treated with early CPAP[3]. A review of prospective studies evaluating early (not delivery room) CPAP in the pre-surfactant, pre-antenatal steroid era found that early CPAP improved survival overall and for infants greater than 1500 gm, and was associated with increased pneumothoraces.[4] A more recent review of prophylactic CPAP started in the delivery room reviewed only 2 available trials and found no significant difference between the CPAP and conventionally managed infants and noted a trend to increased adverse outcomes for the CPAP treated infants.[5]

There is substantial retrospective evidence suggesting a benefit for early CPAP in experiences from both the US and other countries.[67] These reports have documented a decrease in the need for mechanical ventilation among very preterm infants without an increase in morbidity following the initiation of early CPAP treatment.[8910]

The current available evidence demonstrates that prophylactic and early surfactant treatment at less than 2 hours of life significantly decreases mortality, air leak, and BPD in preterm infants.[1112] Overall surfactant has not been reported to significantly reduce BPD, but may do so for the most immature infants and has not been found to significantly reduce subsequent neurodevelopmental impairment (NDI).[13]

The recent COIN trial randomized 610 infants from 25 weeks 0 days to 28 weeks 6 days gestational age at birth, who were able to breathe at 5 minutes of age and had evidence of respiratory distress at that time. Infants were randomized to either intubation and ventilation

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

or CPAP at 8 cm H20. CPAP infants were intubated if they met failure criteria.[14] This study did not compare early CPAP to the early administration of surfactant, and surfactant use followed unit standard of care. There was a significant primary increase in the occurrence of pneumothoraces in the CPAP group (9.1% vs 3.0%, p=.001), most occurring within the first 2 days, consistent with the findings of an earlier meta analyses46, and a reduction in death or the need for oxygen at 28 days in the CPAP infants (odds ratio, 0.63; 95% CI, 0.46 to 0.88; P=0.006) with no difference in death or BPD at 36 weeks.

In view of the current interest in the use of early CPAP and the lack of prospective comparisons of this approach with the evidence based intervention of prophylactic or early surfactant, the SUPPORT study was designed to compare these approaches for the most preterm infants. We also randomized infants to 2 ranges of pulse oximetry targets during their exposure to oxygen using a factorial design, and the results for the oximetry study will be reported separately.

Methods

This was a randomized, factorial 2X2 design multi-center trial conducted by the NICHD Neonatal Research Network. This report describes the prospective comparison of CPAP and a permissive ventilatory strategy begun in the delivery room and continuing in the NICU with the early (< 1 hour) intratracheal administration of surfactant followed by conventional mechanical ventilation.

Infants were also randomized to a prospective comparison of a lower SpO2 range (85% to 89%) with a higher more conventional SpO2 range (91% to 95%) until the infant was no longer requiring ventilatory support or oxygen using purpose altered oximeters. These results will be separately reported.

The primary hypothesis of this trial was that relative to infants managed with prophylactic/early surfactant and conventional ventilation that the use of early CPAP and a permissive ventilatory strategy in infants of 24 to 28 weeks gestation with continuing CPAP in the NICU will result in an increased survival without BPD at 36 weeks.

Comment [AD3]: We should be consistent in either picking death or BPD, or survival without BPD.

Eligible infants were 24 0/7ths to 27 6/7th weeks at birth by best obstetrical estimate, born at a randomizing center, for which a decision had been made to provide full resuscitation, without known malformations, and for whom parental consent had been obtained. The infants were randomized within each center to 2 gestational age strata, 24 0/7ths to 25 6/7ths weeks, and 26 0/7ths-27 6/7ths weeks.

CPAP Arm - Delivery room management: A T-piece resuscitator, a neonatal ventilator, or an equivalent CPAP methodology was used at all sites for the delivery room administration of CPAP. CPAP or ventilation with PEEP both at a recommended 5 cm H_2O was utilized if the infant required positive pressure during resuscitation. CPAP was continued until admission to the NICU using the T-piece resuscitator or equivalent device and a face mask or nasal prongs. CPAP infants were not to be intubated for surfactant only in the DR, and CPAP infants who required intubation for resuscitation were to receive surfactant within 60 minutes of birth. Intubation for these infants was performed only for the standard NRP indications including failure to respond to positive pressure ventilation (PPV) with evidence of continuing cyanosis or bradycardia, the need for chest compressions, the need to administer intratracheal medications, or other situations in which the resuscitation team determined that surfactant is urgently required.

NICU management: Intubation was performed at any time for the occurrence of repetitive apnea requiring bag and mask ventilation, clinical shock, sepsis, and/or the need for surgery. While intubation was never required by protocol, CPAP infants could be intubated if they met any of the following criteria: an FiO_2 >.50 required to maintain an indicated SpO2 $\geq$ 88% for one hour, an arterial $PaCO_2$ > 65 torr documented on a single blood gas, or hemodynamic instability defined as a low blood pressure for gestational age and/or poor perfusion, requiring volume and/or pressor support for a period of 4 hours or more. If intubated within the first 48 hours of life infants were to receive surfactant.

Extubation for CPAP infants was to be attempted within 24 hours if all of the following criteria were met: a PaCO2 < 65 torr with a pH > 7.20, an SpO2 > 88% with an FiO2 < 50%, a mean airway pressure (MAP) < 10 cm H2O, ventilator rate < 15 bpm, an amplitude < 2X MAP if on high frequency ventilation (HFV), and hemodynamically stable, and without a clinically significant patent ductus arteriosus. Re-intubation criteria were the same as those for intubation. After 3 intubations CPAP infants were treated using NICU standard of care.

Surfactant Arm: All infants were to be intubated within 1 hour of life and receive surfactant, followed by continued ventilation. All infants were to be extubated within 24 hours of meeting all of the following criteria: $PaCO_2$ < 50 torr and pH > 7.30 An FiO2 $\leq$ 35 with a SpO2 > 88%, a mean airway pressure (MAP) < 8 cm H_2O, ventilator rate $\leq$ 15 bpm, an amplitude < 2X MAP if on high frequency ventilation (HFV), and be hemodynamically stable with no evidence of clinically significant PDA. Once extubated Surfactant infants were treated using NICU standard of care.

These criteria were in effect for the first 14 days of life, following which the infant was treated as per NICU standard of care. For both arms of the trial intubation could be performed at any

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

time for the occurrence of repetitive apnea requiring bag and mask ventilation, clinical shock, sepsis, and/or the need for surgery.

Randomization was stratified by center and gestational age group, utilizing specially prepared double-sealed envelopes. Deliveries were randomized as a unit, and thus multiples, were randomized to the same arm of the trial.

Hypothesis and sample size: We hypothesized that early CPAP would reduce the incidence of death or survival with BPD at 36 weeks, (using the NRN occurrence of death or survival with BPD of 67% using the year 2000 data), and the occurrence of death or survival with neurodevelopmental impairment (NDI) at 18 to 22 months (using the NRN occurrence of NDI of 61% using year 2000 data) by 10%. We increased the sample size by a factor of 1.12 to allow for multiples to be randomized to the same treatment as this introduced a clustering effect into the design, and increased the sample sizes by a further 17% to adjust for attrition after discharge and before follow-up. This resulted in a sample size of 1312 infants. This sample size was not large enough to determine an interaction effects between the 2 factorial arms.

Comment [AD4]: Since we are not reporting NDI here, and did not adjust our sample size for multiple outcomes, do we need to say this?

In addition there was a prospective decision to also evaluate the occurrence of BPD using the Physiologic Definition which required an attempt at oxygen withdrawal for infants who required < 30% oxygen at 36 weeks and assigned a diagnosis of BPD to any infant who required more than 30% oxygen at 36 weeks or who required positive pressure support. [1516]

Statistical analyses: Intention-to-treat analyses were performed. The denominator used to calculate the rate of each outcome was the number of infants for whom that outcome was known. The primary analyses focused on the percent of each Group who developed their respective outcome measure of survival without BPD at 36 weeks. Adjustment was performed as pre-specified for gestational age, center and familial clustering using robust Poisson regression implemented in a Generalized Estimating Equation (GEE) model to obtain adjusted relative risks. A two-sided P value of less than 0.05 was considered statistically significant. An independent data safety monitoring committee reviewed the interim safety and efficacy results, including those concerning adverse outcomes, four times. Lan-DeMets spending functions with Pocock (O'Brien-Fleming) boundaries were used to develop stopping rules for interim safety and efficacy monitoring. Safety outcomes monitored included death, pneumothorax, intraventricular hemorrhage and a combination of any of the above events.

Comment [AD5]: Let us make the statistical sections of both primary papers as similar as possible.

The study was approved by Human Subjects Committees at all participating sites and RTI, the NRN data center that managed and analyzed all the data, and parental consent for participation in the trial was required before delivery.

Results:

There were 1317 infants enrolled in this trial from Jan 1 2004 through to Mar 1 2009 . The trial was temporarily suspended by the DSMB because of concerns regarding the oximetry data in November 2005 but after a complete review the trial was continued in February 2006 with no protocol changes. The patient descriptive information for the CPAP versus Surfactant arms is shown in Table 1.There were 565 infants enrolled in the lower gestational age strata, and 751 in the higher strata. There were no significant differences for sex, birth weight, Apgar scores or race between the 2 treatment groups. The Surfactant group received significantly more epinephrine in the delivery room and had a trend for higher DR mortality which was not significant.

In the delivery room, 66% of the CPAP infants received positive pressure ventilation compared with 93% of the surfactant infants, and surfactant was given to 14% of the CPAP versus 51% of the surfactant group, and 67% of the CPAP infants received surfactant at any time during their hospitalization, (all $p<0.0001$). Intubation in the DR occurred in 34% of CPAP infants compared with 93% of surfactant infants, $p<0.0001$, Table 2.

The primary outcome of death or BPD, defined as the need for supplemental oxygen at 36 weeks post conceptional age was significantly lower for the CPAP group compared with the Surfactant group, 48% versus 54%, ($p < 0.05$, when adjusted for gestational age, center and familial clustering as prespecified). Death during the hospitalization was 4% lower for the CPAP group overall, and was significantly lower in the CPAP arm for the 24 to 25 week strata. There was a non-significant reduction in the occurrence of BPD using the need for supplemental oxygen, 40% vs 44%, $p=0.27$. Using the Physiologic Definition for BPD there was no decrease in the occurrence of BPD in the CPAP group (40% vs 41%, $p=0.96$), and a non-significant reduction in the occurrence of death or Physiologic BPD at 36 weeks in the CPAP group, (48% vs 51%, $p=0.32$).

There were no differences overall for death in the delivery room nor any differences in length of stay, or days of oxygen for survivors, and the need for oxygen at discharge. (Table 3). More CPAP infants were alive and off mechanical ventilation by day 7, ($p=0.01$). There were no differences between the groups in air leaks in the first 14 days, air leaks during the hospital stay, medical or surgical NEC, PDA requiring surgery, or severe IVH. All infants in the Surfactant arm were intubated, compared with 83% of the CPAP infants who required intubation during their nursery course, ($p<0.0001$). There was a significant reduction in the use of postnatal steroids for BPD in the CPAP infants compared with the Surfactant infants, 7% vs 13%, $p<.001$).

Strata Results: 24 – 25 weeks Gestation

Comment [AD6]: Do we need to preface some justification for looking within strata?

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

There were significantly more non-Hispanic black infants in the CPAP group compared with the Surfactant group. The differences are shown in Table 4 (24-25 wk Strata). CPAP infants had a significantly lower mortality 24% vs 32%, p=0.03. There was a significantly higher exposure to postnatal steroids for BPD, 21% vs 13%, p=0.02 for the Surfactant group, and there were more infants alive and off mechanical ventilation at 1 week in the CPAP infants in this strata.

26-27 weeks Gestation

There was no difference in mortality for the CPAP vs Surfactant groups, 10% vs 11%. The CPAP infants required fewer days of oxygen, 36.8 vs 46.5, p<0.01, lesser days of mechanical ventilation, 10.7 vs 14.2, p<0.01, and less postnatal steroids for BPD, 3% vs 8%, p<0.01.

Discussion:

The SUPPORT trial is the first multicenter trial to compare early CPAP with early surfactant given within an hour of life in ELBW infants. The current trial is the largest study reported to prospectively compare the use of early CPAP and early surfactant for the ELBW infant and the only study to include infants of 24 weeks gestation. In a preliminary study we found that 100% of infants of 23 weeks gestation required intubation in the DR, and thus decided that such infants would be unlikely to be successfully treated with CPAP alone following delivery.[17] Others have retrospectively reported that some of these infants can be successfully managed with early CPAP, but the majority of such infants require intubation.[18]

Our study differs from the recently reported COIN trial[14,14] in that we randomized all eligible ELBW infants of consenting families irrespective of whether they demonstrated spontaneous breathing, included infants of 24 weeks gestation and compared the CPAP/permissively ventilated infants with infants who all received surfactant within 1 hour of birth. Our method of using early CPAP and a permissive ventilation strategy was a result of previous retrospective reviews of practice which demonstrated that the unit with the most success using CPAP also utilized a very permissive approach for intubation and the initiation of mechanical ventilation. **Error! Bookmark not defined.**8 We believed that testing this complete approach would provide a more relevant result as most units currently using early CPAP also tend to be permissive in their use of intubation.

Formatted: Font: 12 pt, Superscript

Our study has demonstrated that early CPAP and a permissive ventilator strategy when compared with surfactant given within 1 hour of birth is associated with a significant reduction in death or survival with BPD as defined by the need for oxygen at 36 weeks from 54% to 48%. We also noted a very significant 8% reduction in death in our 24 to 25 week strata, resulting in a number needed to treat of 12.5 for each additional survivor. The group of 565 infants in our 24 to 25 week strata to our knowledge represents the largest prospective group of such immature infants to be randomized in any neonatal trial evaluating respiratory interventions. We believe

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

that this lower incidence of death in these infants along with a reduction of BPD and decreased durations of ventilation and exposure to post natal steroids in the overall CPAP group represents a substantial clinical benefit compared with the initial use of early surfactant.

Our rates of BPD are higher than those reported for the COIN trial, 33.9% vs 38.9%, but the difference between the arms is very similar. The higher rates seen in our study no doubt reflect the inclusion of infants of 24 weeks gestation and the lack of inclusion of infants greater than 27 6/7ths weeks, as well as the requirement in the COIN trial that the infants demonstrate adequate spontaneous breathing at 5 minutes of life.

We prospectively identified a number of safety outcomes that we chose to follow as investigators. These included the need for compressions in the delivery room, the occurrence of severe IVH, and the incidence of airleaks, initially defined as pneumothoraces but later altered to include pulmonary interstitial emphysema, pneumomediastinum and pneumopericardium. We did not find an increase in airleaks with the use of early CPAP at 5 cm H2O compared to the use of early surfactant.

The SUPPORT study was designed as a factorial design with each infant randomly receiving 2 interventions, CPAP vs Surfactant, and a lower versus higher SpO2 target range. While the study was not powered to detect an interaction between the 2 interventions, we did prospectively agree to evaluate such interactions and none were found. Both arms of the study were adequately powered for both the outcomes at neonatal discharge and the occurrence of survival NDI at 18 to 22 months and these results will be presented after all survivors have been assessed.

Conclusions:

ELBW infants between 24 and 27 6/7ths weeks gestation at birth treated with CPAP and a permissive ventilator strategy compared with the use of surfactant within 1 hour of birth and conventional mechanical ventilation have a decreased incidence of death or survival with BPD based on the need for oxygen at 36 weeks PCA with no demonstrable increase in any adverse neonatal outcomes. Early CPAP with a permissive ventilator strategy is associated with a significant reduction in mortality in the most immature infants. Surviving infants will have a complete neurodevelopmental evaluation at 18 to 22 months and these results will be separately reported.

---

Hi Rose

Here is the protocol with Krisa's name back on the front page. I have no idea when or where it dropped off.

Thanks -

Susan

I) INTRODUCTION:

The **Surfactant Positive Airway Pressure and Pulse Oximetry Trial (SUPPORT)** is a prospective, randomized, factorial 2x2 design multi-center trial conducted by the NICHD Neonatal Research Network (enrollment completed February 2009). The trial will evaluate if CPAP and a permissive ventilation strategy and lower SpO_2 targets (85-89% vs. 91-95%) will result in increased survival without bronchopulmonary dysplasia (BPD) and increased survival without retinopathy of prematurity (ROP) among 24-27+6/7 week EGA infants. **The SUPPORT Neuroimaging and Neurodevelopmental Outcomes Study** is a prospective secondary study to SUPPORT of cranial ultrasound (CUS) at 4-14 days ("early CUS") and 35-42 weeks postmenstrual age (PMA) ("late CUS"), and brain MRI at 35-42 weeks PMA among infants enrolled in SUPPORT. The study was launched in May 2005, and 16 NICHD NRN sites participated. This study will allow us to assess the comparative and combined capabilities of early and late CUS and brain MRI to predict neuromotor and neurodevelopmental outcome at 18-22 months corrected age. The SUPPORT Neuroimaging and Neurodevelopmental Outcome cohort will be the largest such cohort assembled to date.

Children born extremely prematurely continue to have significant neurodevelopmental challenges in later childhood, yet many subtle but significant cognitive and performance problems cannot be delineated until school age. Early and accurate prediction of neurodevelopmental outcome would be invaluable, but CUS and other early variables do not reliably predict outcomes. White matter (WM) injury has been strongly implicated in neuromotor and cognitive impairment, and a link between WM injury and gray matter developmental disruption appears to exist. MRI is better than CUS in identifying subtle and diffuse WM injury, as well as cerebellar and gray matter abnormalities. Previous studies of preterm infants have shown WM injury by MRI to be significantly associated with CP and adverse *neurosensory* outcome, independent of CUS abnormalities. An independent association with *cognitive* impairment in early childhood has not yet been demonstrated. However, subtle neonatal MRI abnormalities may predict cognitive problems in early school age that cannot yet be delineated at 18-24 months. In addition, higher rates of behavioral and executive function impairments in childhood have been reported among very preterm infants, and previous studies have suggested that WM injury seen on neonatal MRI may predict these impairments. **We therefore propose to follow the SUPPORT Neuroimaging cohort at 6½ - 7½ years to test the primary hypothesis that neonatal brain MRI is superior to neonatal CUS in predicting death after discharge or cognitive impairment (Wechsler Intelligence Scale for Children-IV (WISC-IV) IQ<70) at school age.** We will also test whether neonatal brain MRI is superior to CUS in predicting neuromotor impairment, disability, and less severe cognitive impairment. We will also assess whether injury severity on neonatal MRI is associated with longitudinal cognitive and disability level changes, examine cognitive impairment and disability between ventilatory and oxygenation saturation SUPPORT intervention groups, and determine whether neonatal MRI is superior to CUS in predicting adverse executive and behavioral outcomes.

The SUPPORT Neuroimaging cohort is valuable and unique among other preterm cohorts worldwide. By pursuing 6½ - 7½ year follow-up, the NICHD NRN is in an outstanding position to substantially contribute to our understanding of later extremely preterm outcomes and their prediction.

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

II) HYPOTHESES:

Among children enrolled in the SUPPORT Neuroimaging and Neurodevelopmental Outcome Secondary with complete neuroimaging and surviving to hospital discharge:

PRIMARY:

- Neonatal brain MRI will be superior to neonatal CUS in predicting death after discharge or cognitive impairment (WISC-IV IQ<70) at 6½ - 7½ years.

SECONDARY:

- Neonatal brain MRI will be superior to neonatal CUS in predicting cognitive impairment (WISC-IV IQ<70) at 6½ - 7½ years.
- Neonatal brain MRI will be superior to neonatal CUS in predicting death after discharge or disability, or disability among survivors, at 6½ - 7½ years.
- There will be insufficient evidence to reject the null hypothesis that no differences exist in the risks of cognitive impairment, disability, or neuromotor impairment including CP between ventilatory or oxygenation saturation SUPPORT intervention groups in this sub-cohort.
- Neonatal brain MRI will be superior to neonatal CUS in predicting mild cognitive impairment (WISC-IV IQ 1-2 SD below population mean) at 6½ - 7½ years.
- Neonatal brain MRI will be superior to neonatal CUS in predicting CP and neuromotor/movement impairment at 6½ - 7½ years.
- Moderate to severe white matter injury on neonatal neuroimaging will be associated with behavior and executive function impairments at 6½ - 7½ years.
    - Neonatal brain MRI will be superior to neonatal CUS in predicting behavioral and executive function impairments at 6½ - 7½ years.
- Severe developmental impairment and severe cerebral palsy at 18-22 months will be highly predictive of severe disability at school age, but mild or moderate impairment at 18-22 months will be poorly predictive of later outcome group.
- Injury severity and pattern on neonatal MRI will be associated with longitudinal cognitive and disability level changes (18-22 months corrected age → 6½ - 7½ years).
- Brain injury pattern and topography on neonatal MRI will be associated with anatomic and functional type of CP at school age.
- High rates of health-related quality of life challenges and chronic or disabling conditions will be observed.
    - These findings will be associated with moderate-severe brain injury on neonatal neuroimaging.
- Local readings of neonatal MRI will be less predictive of 6½ - 7½ year outcomes than central reading.

Specific Aims:

- To assess cognitive, neuromotor, functional and behavioral outcomes of the SUPPORT Neuroimaging cohort at 6½ - 7½ years of age
- To examine the independent associations of neonatal neuroimaging findings with neurodevelopmental outcomes
    - Assess the absolute and relative value of early and late neonatal CUS and neonatal MRI, alone and in combination with other risk factors, to predict normal and impaired outcomes

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

- To examine longitudinal changes in cognitive and overall impairment level from 18-22 month to 6½ - 7½ year exams, and assess relationship of neonatal neuroimaging abnormalities and other variables.
- To compare 6½ - 7½ year neurodevelopmental outcomes of ventilation and oxygenation SUPPORT randomized groups in this sub-cohort.

II) BACKGROUND AND SIGNIFICANCE:

Long-term neurodevelopmental outcomes of extremely preterm infants:

Despite advances in perinatal and neonatal management and improvement in survival, short-term neurodevelopmental outcomes of extremely preterm and extremely low birth weight (ELBW) infants remain guarded (Vohr, Hintz #1, Hintz #2, Costeloe). This high frequency of disability in very early childhood (18-24 months) makes longer-term neurodevelopmental outcome studies crucial. Evaluation at a later age allows identification and delineation of a broader range of problems, including cognitive delay, more subtle motor, movement, and coordination disabilities, and behavioral and executive function problems to be determined. It also allows for assessment of the strength of perinatal and neonatal variables as potential predictors of long-term outcomes, and for longitudinal analysis to determine the predictive value of early disability.

Later childhood follow-up studies have demonstrated that significant neurodevelopmental and cognitive impairment continue for extremely preterm infants. In the 206 ELBW infants followed at 5 years in the Finnish National Cohort (Mikkola), 20% had major disabilities, and 19% of those <27 weeks were diagnosed with cerebral palsy (CP). The EPICure Study Group (Marlow) reported on 241 <26 week survivors at 6 years; severe overall cognitive delay was present in 21% compared with test norms (41% compared with term controls), and disabling CP was diagnosed in 13%. In a study of 219 ELBW infants at 8 years (Hack #1), Hack, et. al. reported CP in 14%, severe cognitive impairment in 15%, moderate-severe cognitive impairment in 38%, and significant motor skills problems in 27%. Families reported substantial functional limitations, including emotional delay, trouble understanding or communicating, and need for medication or equipment. Needs for special services were significantly greater than for the normal birth weight (NBW) control group. Impairment in academic (32%) and adaptive skills (48%) have also been reported among ELBW children, and are significantly more frequent than in NBW controls (Taylor). In an ELBW or <28 week EGA cohort at 8 years (n=275), Anderson, et. al. reported significant impairment across all tested cognitive and educational abilities compared with NBW controls (Anderson #1). Although improvements in neurosensory impairment rates have reported over time with successive ELBW birth cohorts in VICS since the 1970's, neurologic disabilities continue to be substantially more common among ELBW children at school age than their normal birth weight peers (Doyle #1).

Summary: Children born extremely preterm or ELBW continue to have significant motor and cognitive disabilities in childhood, as well as more subtle functional and adaptive impairments. Delineation of some of these problems may not even be reasonably undertaken until 5-8 years of age. The true impact of these impairments may not be felt until later school age (Saigal).

Neonatal CUS and other variables to predict neurodevelopmental outcomes

CUS and short-term outcomes (18-24 months)

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

The association of severe neonatal CUS abnormalities and adverse short-term neurodevelopmental outcome has been reported in numerous studies (Vohr, Hack #2). But the strength of this association appears to be consistent primarily for combined developmental and neuromotor endpoints, or for CP or motor disability alone, but not for pure cognitive delay (deVries, Hack #2, Wood). In addition, severe CUS abnormalities are not uniformly predictive of adverse short-term outcome and normal CUS do not predict normal outcome in this high-risk population (deVries, Hack#2, Laptook, Ancel, Pinto-Martin). In fact, in a predictive modeling analysis, Ambalavanan found that severe grade of IVH explained only 8% of the variance in low MDI and 5% of the variance for major handicap at 18-22 months (Ambalavanan).

CUS and long-term outcome (5-8 years)

Reported associations of neonatal CUS findings and long-term outcomes are inconsistent. Sherlock, et. al. (Sherlock) reported that neurodevelopmental impairment at 8 years varied little with increasing severity of IVH; a trend for worse cognitive and neurosensory outcome with higher grade IVH in that study was explained solely by the outcomes of the small number of patients with parenchymal hemorrhage. The Neonatal Brain Hemorrhage Study (NBHS) showed that 88% of LBW patients with germinal matrix or IVH had normal cognitive outcomes (Whitaker) at 6 years.

Nevertheless, several analyses have reported abnormal neonatal CUS to be "significantly associated with" adverse long-term neurodevelopmental outcomes in ELBW cohorts. For instance, Mikkola found an association of abnormal CUS with CP and IQ at 5 years (Mikkola), and Taylor found an association of abnormal CUS with executive function and memory on the NEPSY (Taylor). However, the definition of CUS "abnormality" varies among studies, with some analyses including markers of white matter injury (PVL or ventricular enlargement (VE)) and others limiting only to IVH. In addition, a finding of association does not specifically address the independent *predictive* power of neonatal CUS, particularly with respect to cognitive outcome in later childhood. In fact, Hack, et. al. demonstrated that only 36% of those with a Mental Processing Composite (MPC) of <85 at 8 years had had an abnormal CUS, and only 45% of those with MPC<70 (Hack #3). In the 6-year follow-up of the NBHS cohort, only 12% of those with GM/IVH had borderline IQ or mental retardation (Whitaker). In that study, PVL/VE was separately assessed; this revealed a stronger 56.5% of those with PVL/VE had borderline IQ or mental retardation. This may be a clinical insight to the importance of white matter (WM) injury for longer-term adverse outcomes *including cognitive outcomes*. Nevertheless, more that 40% of patients with PVL/VE had normal intelligence at 6 years - a finding, which, in turn, may serve to underscore the inability of routine CUS to see anything more subtle than the most definitive WM injury.

Other potential predictors of long-term neurodevelopmental outcome:

Investigators have attempted to determine other, more reliable predictors of longer-term outcomes of preterm infants. Doyle reported on prediction of survival free of major disability at 5 years among the surviving VICS cohort on the basis of the *number of adverse neonatal variables* experienced by the child (Doyle #2). Although observed and predicted values were similar, the outcome was not specifically focused (i.e., combined neurologic/neurosensory/cognitive endpoint), the observed 95% CI range was broad for 2 and 3 variable groups, and the patient numbers were quite small. Others have assessed the predictive value of *earlier neurodevelopmental findings*. Marlow found that only severe

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

disability at 30 months was highly predictive of 6-year outcome; 38% of children defined as mild or moderately disabled and 24% with "no disabilities" had moderate or severe disabilities at 6 years. Hack (#3) found the positive predictive value of MDI<70 at 20 months for MPC<70 at 8 years to be extremely poor (PPV=0.37). However, some intriguing links between neonatal brain injury and longitudinal decline in cognitive ability have been reported. In follow-up to the I-IVHP trial, Ment found that cognitive scores declined from 36 to 96 months only in the subset of patients with early IVH coupled with PVL or VE (Ment). Also from the I-IVHP trial, the presence of spastic cerebral palsy at 3 years was more strongly predictive of IQ<70 at 8 years than was cognitive testing at 3 years (Pleacher). These findings are interesting, but perhaps not surprising, in light of the proposed mechanism linking white matter injury with reduced connectivity, gray matter loss, and cognitive delay (Boardman, Inder).

Summary: Aggregate abnormal findings on neonatal CUS do not reliably predict either short- or long-term neurodevelopmental outcomes, although markers of WM injury appear to be stronger links. Early cognitive measures also do not predict later cognitive outcome well in most circumstances. These findings emphasize the deficits of routine CUS to detect subtle injury, and also underscore the poor predictive validity of early cognitive measures for later cognitive outcomes (Aylward). These findings also suggest that better delineation of neonatal WM injury may enhance efforts to predict outcomes.

MRI: Delineation of injury and predicting outcomes

Imaging brain injury:

MRI provides a more complete and anatomically detailed evaluation of the neonatal brain. Studies comparing the relative capabilities of US with MRI to detect brain injury among preterm infants in the newborn period have shown that MRI detects white matter injury better than CUS (Maaloof, Childs), and provides additional information on brain development not noted by cranial US. Studies have also demonstrated that subtle and diffuse WM injury, not detectable by CUS, may be common among preterm infants at term (Counsell).

White matter injury and cognitive outcome:

Cognitive delay is a significant impairment and difficult to predict. Recent studies have demonstrated that WM injury in the preterm infant is associated with both reduced cortical gray matter volume, and with reduced deep gray matter volume by MRI at term equivalent age (Inder, Boardman). There are several potential mechanistic pathways, including via direct axonal or subplate neuron injury that may explain this finding. The common endpoint is reduced connectivity, limited neuronal differentiation, and poor cognitive outcome. In fact, recent research using MRI tractography in a series of former preterm infants at approximately 2 years of age has provided at least proof of concept for this theory of reduced cortical and thalamic connections after WM injury (#2 Counsell).

Brain and WM injury by MRI and executive and behavioral outcomes in preterm infants:

Extremely low birth weight and very preterm infants have been reported to be at greater risk for executive dysfunction, as well as emotional and behavioral problems at 2 years, 4 years and at school age (#2 Anderson, Woodward #1, Taylor). These problems are infrequently the focus of neurodevelopmental outcomes studies, and are considered by some to be less serious than cognitive impairment. However, impairments across these domains have substantial impact on academic achievement, follow-up needs, and family

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

interactions. Recent studies have suggested that these impairments may be associated with specific brain injury types and patterns among preterm children. In a brain diffusion tensor imaging (DTI) MRI study of preterm and term adolescents, Skranes, et. al. (Skranes) demonstrated that the preterm group were more likely to have attention deficit hyperactivity disorder (ADHD) and autism spectrum disorder (ASD) diagnoses or symptoms. Those with ADHD and ASD had lower fractional anisotropy (FA) in many WM areas, consistent with WM injury and impaired WM connectivity throughout the brain. Recent analyses have also demonstrated that WM injury on near-term MRI may predict executive and behavioral problems among preterm infant in early childhood. In a single center study, abnormal near-term MRI in VLBW infants was associated with positive M-CHAT screen in early childhood (Limperopoulos). Impaired working memory performance (Woodward #2) and self-regulation (Clark) at 2 years have both been associated with moderate-severe WM injury on near-term MRI. Specific regional injury patterns have furthermore been associated with working memory deficits.

MRI in preterm infants and early neurodevelopmental outcome

After early studies suggesting that MRI at near term was a more powerful predictive tool than CUS for short-term neurodevelopmental outcome (Valkama, Roelents-van-Rijn, Mirmiran), larger MRI studies were undertaken. Many have been single-center efforts, focused chiefly on the association of early neurodevelopmental outcomes with MRI findings in preterm infants at term and earlier, and without extensive comparison of the predictive validity of MRI and CUS. Among these, Miller, et. al. (UCSF, <34 weeks EGA, 86 survivors) and Dyet, et. al. (Hammersmith, <30 weeks EGA, 119 survivors) described MRI findings from birth through near-term and found that WM injury, particularly diffuse injury, was common and was associated with adverse neurodevelopmental outcomes. Recent evidence has also suggested that WM injury on neonatal MRI predicted motor developmental delays at 1 year corrected age with high specificity among very preterm infants (Spittle). Cerebellar injury, not easily seen with routine CUS, was also a prognostic indicator of poor outcome. Of importance, although MRI data were meticulously obtained, only 66% of the group had complete follow-up information.

However, other groups have preterm MRI cohorts, with research aims that include comparison of predictive capabilities of MRI and CUS.

- The 2-year neurodevelopmental outcomes of the New Zealand (NZ) cohort (Woodward #3) (<30 weeks EGA, 167 survivors) revealed that 1) presence of moderate-severe WM abnormalities on MRI was significantly associated severe motor delay and cerebral palsy, independent of CUS abnormalities and other risk factors; 2) a significant correlation between white and gray matter abnormalities; 3) although increasing severity of WM injury was associated with worse Bayley MDI scores, an independent association of moderate-severe WM injury with severe cognitive delay was not reached. Although sensitivity of moderate-severe WM to predict CP (65%), neurosensory impairment (82%) and severe cognitive delay (41%) was improved over abnormalities on CUS (18%, 16%, and 15%, respectively), the total number of the cohort with moderate (n=29) or severe (n=6) WM injury was small, and approximately half of those did not have neurodevelopmental impairment.
- The 2-year results of the Australian cohort (<1250 g or <30 weeks EGA, n=221) (Hunt) showed "major" white matter injury to be a more significant independent risk factor than PVL for CP. Major WM injury was found to be an independent risk factor for

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

neurosensory disability where PVL was not. IVH grade 4 was not found to be a significant risk factor for either outcome.

- **SUPPORT Neuroimaging and Neurodevelopmental Outcomes cohort:** The birth date of the first enrolled patient was 5/10/05. Enrollment was completed with SUPPORT main trial in February 2009, and follow-up at 18-22 months is ongoing.

SUPPORT Neuroimaging cohort: Unique and valuable

The SUPPORT Neuroimaging cohort, comprised of ~530 extremely preterm infants surviving to near-term with complete CUS and MRI neuroimaging will be the largest preterm brain MRI cohort worldwide with comprehensive early childhood follow-up. This cohort is also a higher-risk group than other cohorts, and thus targets one of the most important outcomes groups. The SUPPORT Neuroimaging cohort is inherently exceptional due to its development within a randomized controlled trial. Thus, the management profile of a crucial neonatal care component has been more carefully controlled and monitored than would otherwise be the case. This also allows for secondary analyses of the association of respiratory management strategies with subtle MRI findings and with outcomes. The SUPPORT Neuroimaging cohort also has a number of advantages over other preterm/MRI cohorts:

1) New Zealand (NZ) cohort:
    a. Setting: SUPPORT: Embedded in a randomized controlled trial within a multicenter network with focused neurodevelopmental follow-up priorities; NZ: two centers one in New Zealand another in Melbourne, Australia, with a primary focus on MRI imaging
    b. EGA/risk profile:
        i. SUPPORT: <28 weeks EGA; NZ cohort: <30 weeks. In the NZ cohort, only 87/167 were <1000 g BW, and 95/167 were <28 weeks.
    c. Cohort size: SUPPORT: ~530 survivors to near-term; NZ: 167 survivors at 2 years.
    d. Timing/interpretation of CUS:
        i. SUPPORT: Two CUS required by the study protocol at specific times (4-14 days and near-term); NZ: number and timing of CUS not required as part of study protocol, but reported CUS usually obtained within 2 days, 5-7 days, 4-6 weeks; if "abnormality" detected, more frequently performed.
        ii. SUPPORT: central reader, detailed data collection; NZ: No central reader. "Worst" CUS findings recorded only related respect to PVL/echolucency, grade 3 or 4 IVH
    e. Timing/interpretation of MRI:
        i. BOTH: Near-term
        ii. BOTH: Central reader
        iii. SUPPORT: detailed MRI central reader data collection form; NZ: central reader data collection instrument not known, but MRI abnormality categories broad.
    f. Non-imaging data collection:
        i. SUPPORT: extensive, including detailed respiratory data; NZ: less detailed
2) Australia cohort:
    a. Setting: Single center in Melbourne, Australia

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

b. EGA/risk profile:
    i. <30 weeks, <1250 g.
c. Cohort size: 221 survivors at 2 years.
d. Timing/interpretation of CUS:
    i. Not required, retrospectively gathered data (communication, Rod Hunt).
    ii. "Worst" CUS findings gathered - PVL, grade 4 IVH
e. Timing/interpretation of MRI:
    i. Near-term
    ii. Central reader
f. Non-imaging data collection:
    i. Routine

3) Hammersmith cohort:
    a. Setting: Single center
    b. EGA/risk profile:
        i. <30 weeks.
    c. Cohort size: 119 survivors at 2 years. **Note: complete follow-up data were available for only 66% of the group**
    d. Timing/interpretation of CUS:
        i. CUS not focus – studies thus far report MRI
    e. Timing/interpretation of MRI:
        i. MRI serial – from birth to near-term
        ii. Central reader
    f. Non-imaging data collection:
        i. Routine
4) UCSF:
    a. Small, single center
    b. <34 weeks
    c. 86 survivors at 2 years
    d. CUS not focus – MRI's serial from birth to near-term
    e. Non-imaging data routine

Summary: MRI is better than CUS in identifying subtle and diffuse white matter injury, which is relatively common among preterm infants at term, as well as cerebellar, and gray matter abnormalities. Early small and single-center studies suggested that MRI better predicts adverse neuromotor outcome than CUS. Two-year results of the NZ cohort have shown WM injury by MRI to be significantly associated with CP and adverse neurosensory outcome independent of CUS abnormalities, but not with adverse cognitive outcome. The extent to which these findings will be enhanced and clarified, and how or when MRI should be applied in routine clinical practice, awaits the 18-22 month follow-up results of the larger, higher-risk SUPPORT Neuroimaging cohort. However, a biologic mechanism exists for the link between WM injury and cognitive impairment. Early neurodevelopmental findings are poor predictors of later challenges, but subtle neonatal WM abnormalities by MRI may predict cognitive, behavioral, and executive function impairments at school-age that cannot be delineated at 18-22 months.

Later outcomes: Need for SUPPORT Neuroimaging extended follow-up

Evidence for altered brain development: Corroboration of need for long-term follow-up

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

Short-term neurodevelopmental outcomes are only a tiny window into the future of a former preterm child. Difficulties in cognition, performance, verbal/language skills, attention and behavior may not be delineated until later ages. There are also data to support the concept that even minor, undiagnosed brain injury sustained preterm infant is associated with disordered brain development. Rademaker, et. al. found that even minor differences in lesion severity on MRI performed at 8 years of age in <32 week EGA appeared more accurate in prediction of IQ and total impairment score than neonatal CUS (Rademaker). These findings may suggest that subtle injury could have been seen on *neonatal* MRI, which in turn, could have aided in prediction. In a DTI and volumetric MRI study, Yung demonstrated that *neurologically normal* LBW preterm infants at 8-12 years had significantly reduced WM volumes than term controls, and that this was significantly related to reduced IQ (Yung). This finding again suggests that early WM injury leading to reduced volume may have been identifiable on neonatal MRI. Kesler, et. al. described high-resolution MRI results from 73 preterm and 33 term infants at 7-11 years of age; preterm infants had disorganized cortical development, potentially involving disrupted neural migration (Kesler).

Importance of SUPPORT Neuroimaging secondary long-term follow-up

- Our current ability to predict later childhood outcomes from perinatal and neonatal variables is limited. The prognostic validity of neonatal CUS findings is limited, particularly for cognitive outcomes. Even early childhood neurodevelopmental outcome, apart from severe impairment, do not accurately predict later childhood neurocognitive outcome. MRI holds promise as a better predictive modality, but neonatal MRI has not been evaluated on a large scale with respect to long-term, school-age outcomes.
- Performance skills are different at 18-22 months than 6½ - 7½ years. Assessments at the later age may uncover subtle, yet significant problems, including attention/behavior problems, language and verbal delays, and academic impairment, which may be predicted by neonatal WM brain injury seen by MRI.
- The SUPPORT Neuroimaging and Neurodevelopmental Outcomes secondary was designed with MRI/CUS predictive comparison in mind.
- 18-22 month follow-up is already part of this secondary study. Thus, there is a crucial and rare opportunity to evaluate longitudinal neurodevelopmental changes, and importantly, how neonatal brain injury patterns and other variables may be associated with changes in cognitive or functional outcomes over time.
- This is a prospectively enrolled secondary cohort, embedded within SUPPORT RCT. These patients have therefore had a more consistent respiratory management approach, and comprehensive respiratory data collection. This provides a unique opportunity for analyses of randomized ventilation/oxygenation arms of Neuroimaging cohort outcomes at 6½ - 7½ years.
- Neurodevelopmental follow-up is already a focused objective of the NICHD NRN, and extended 6-7 year follow-up has recently been undertaken for a previous trial (Shankaran). In developing this SUPPORT Neuroimaging school-age follow-up protocol, we have been able to utilize experience gained from the challenges faced during the previous extended follow-up project.
- Other preterm/MRI cohorts, notably the NZ cohort, already have moved forward with longer-term follow-up (Clark, Woodward #1).

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

III) STUDY DESIGN:

Objective: This is a prospective, extended follow-up study of 6½ - 7½ year neurodevelopmental outcomes of the SUPPORT Neuroimaging Secondary cohort. We will evaluate and compare the capabilities of *neonatal neuroimaging* - CUS and near-term MRI – to predict cognitive impairment, disability, and neuromotor impairment at 6½ - 7½ years. We will evaluate longitudinal changes in neurodevelopmental outcome, and assess associated neuroimaging findings and other variables. We will also determine if ventilatory or oxygenation saturation SUPPORT interventions are associated with differences in 6½ - 7½ year neurodevelopmental outcomes.

Outcomes:

- Primary:
  - IQ by WISC-IV<70 or death after discharge
- Secondary:
  - IQ score (continuous) by WISC-IV among survivors
  - Disability
    - Severe: Any of: WISC-IV>3 SD below mean, severely impaired neuromotor/functional outcome (non-ambulatory, GMFCS level 4-5), profound hearing loss or blindness (not functionally correctable),
    - Moderate: Any of: WISC-IV2-3 SD below mean, moderately impaired neuromotor/functional outcome
    - Mild: Any of: WISC-IV1-2 SD below mean, mildly impaired neuromotor/functional outcome (abnormal neurologic exam, but walking independently, GMFCS level 1-2)
  - Neuromotor, movement
    - Cerebral palsy, classified anatomically and functionally according to Definition and Classification of Cerebral Palsy, February 2007 guidelines (Baxter) ; Motor and coordination impairment, as determined by administration of the Movement Assessment Battery for Children, version 2 (M-ABC-2) (Burns, Smits-Engelsman).
  - Mild-moderate cognitive impairment (WISC-IV 1-2 SD below mean), severe cognitive impairment (WISC-IV 2-3 SD below mean), and profound cognitive impairment (WISC-IV>3 SD below mean)
  - Executive function and achievement delays (evaluated by NEPSY-II subtests; Behavior Rating Inventory of Executive Function (BRIEF, parent form) (Roze); Woodcock-Johnson III subtests (Taylor))
  - Behavioral and attention deficits (evaluated by Strengths and Difficulties Questionnaire (SDQ) (Goodman, Muris); Conners' Rating Scale (ADHD short form only); Social Communication Questionnaire (SCQ) (Chandler, Eaves))
  - Chronic conditions and health-related quality of life concerns (evaluated by the Questionnaire for Identifying Children with Chronic Conditions – revised (QUICCC-R) (Stein); the Pediatric Quality of Life Inventory (Peds QL) (Majnemer))

Study population:

- The study population (SUPPORT Neuroimaging cohort) will be comprised of the SUPPORT Neuroimaging and Neurodevelopmental Outcome Secondary enrollees

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

who survived to discharge, with complete neuroimaging. **It is estimated that approximately 530 patients meet these criteria.**

- As described in the SUPPORT Neuroimaging and Neurodevelopmental outcome secondary, these patients will have had two CUS (early: 4-14 days of age; late: 35-42 weeks and within 5 days of MRI) and a brain MRI at 35-42 weeks.
    - The CUS with the most severe abnormalities (the "worst" CUS) will be used in comparative analyses
- Estimated cohort size at the time of neurodevelopmental follow-up
    - Follow-up at 18-22 months (ongoing)
        - Estimate 3% death after discharge, 10% loss to F-U:
            - **Cohort=~460 patients**
    - Follow-up at 6½ - 7½ years
        - Estimate additional 20% loss to follow-up:
            - **Cohort = 370 patients**

Design:

- This study is a long-term cognitive, neuromotor, functional, executive function, behavioral assessment of the SUPPORT Neuroimaging cohort at school age (6 ½ - 7 ½ years). **No further neuroimaging is being proposed**.
- Visit at 6½ - 7½ years:
    - The visit battery was assembled and revised after extensive discussions with Protocol Review Subcommittee, Extended SUPPORT Neuroimaging and Neurodevelopmental Outcomes Subcommittee, external advisory reviewers, NRN Follow-up PI group, NRN site psychologists, and evaluation of the challenges and successes of the Extended Hypothermia Follow-up study. The following issues were particularly addressed:
        - Length of visit: Tests and questionnaires were chosen to balance the need for robust neurodevelopmental evaluation, but remain within the confines of a reasonable academic study visit period.
        - Age at visit: Due to differences in age at school start across the U.S., as well as the fact that the WISC-IV "floor" is at 6 years 0 months, there was strong concern that a 6-7 year window would be suboptimal. Therefore, the follow-up window for this study is 6 ½ - 7 ½ years, which will hopefully ameliorate the potential for insufficient sensitivity of WISC-IV for low functioning children at very young ages, and allow for more consistent school exposure across the cohort.
        - Language for tests and questionnaires: There was consensus that tests and questionnaires should be available and normed in Spanish, particularly the instrument used for the cognitive evaluation (primary outcome). It is noted that the NEPSY-II is not available in Spanish. However, site "credit" for a visit will not be linked to attempt of the NEPSY-II in the case of Spanish-speaking children. Furthermore, the BRIEF (parent questionnaire) is available in Spanish, providing some input on the child's executive function.
    - Following is the test and questionnaire grid; note that the child testing and parent questionnaires can be administered simultaneously. Furthermore, the "Break" as presented is a suggested timing. It is understood that each child is an individual, and the NRN site psychologist will determine timing and number of breaks throughout the visit for that particular child's needs.

Statistical considerations:

Analyses:

- Since we are concerned with the relative diagnostic power of the MRI versus the CUS, an appropriate statistical methodology is an ROC analysis. This analysis is based on the sensitivity and specificity and compares the diagnostic power over the entire range of the diagnostic variable(s) and thus negates the need to select "cut points". The analysis related to the primary hypothesis will compare the ROC curves for a predictive model based on the MRI data versus a predictive model based on the CUS data. The WISC-IV < 70 or death after discharge will be the primary outcome variable. The WISC-IV < 70 among survivors will also be evaluated as an outcome variable.
    - We will conduct the ROC analysis with WISC-IV <70 (or death after discharge) as the outcome when either MRI or CUS data are in the predictive model and will compare the ROCs for the two models for statistical significance. Since MRI and CUS are done on the same subjects, it will not be necessary to adjust for risk factors in comparing the two tools.
        - In separate analyses, NRN center may be entered as a variable to assess the confounding effects of site. Although CUS and MRI are

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

centrally-read, and significant attempts to ensure reliability and consistency of WPPSI evaluation across sites will be made, unanticipated and unmeasurable differences between sites in quality of neuroimaging or in WISC-IV administration *may* confound analyses;

- We will conduct the ROC analysis with WISC-IV <70 (or death after discharge) as the outcome when only "traditional variables" (non-neuroimaging variables) are the only variables in the model;
- We will also do the ROC analysis that compares the contribution of MRI and CUS to the prediction of outcome above and beyond that of the traditional clinical variables.
- Will also do the ROC analysis that compares the incremental value of adding MRI to the prediction of outcome above and beyond that of traditional clinical variables plus CUS
- Logistic regression analysis will be used to compare 6½ - 7½ year neurodevelopmental outcomes (or death after discharge) between oxygenation and ventilation SUPPORT randomized groups. These analyses will be adjusted for baseline risk variables.
  - The baseline risk variables pre-specified for adjustment in the main SUPPORT trial are the stratification variables (NRN site and GA group). In comparing 6½ - 7½ year outcomes between SUPPORT randomized groups, we plan to adjust only for these variables in our initial approach. However, since the Neuroimaging cohort may not be representative of the originally randomized study cohort, we will investigate differences between the 6½ - 7½ year follow-up groups and consider a subsequent level analysis adding other factors if there is an indication of systematic differences.
- Local vs. central neuroimaging secondary analyses: As recommended by the Protocol Review Subcommittee, secondary analyses including evaluation of local MRI reading will be undertaken.
  - Local CUS readings are already collected in the SUPPORT or GDB database; local MRI readings (print-out of final local read with study ID and center written on the document, but patient identifiers removed or blacked out) will be collected.
  - Accuracy of local compared with central neuroimaging interpretation will be performed by sensitivity and specificity analyses (Hintz #3).
  - Additional analyses will compare capability of local MRI read and central MRI read to predict 6½ - 7½ year outcomes by ROC analysis.

- "Traditional non-neuroimaging variables": Based on previous investigations assessing the associations of demographic, socioeconomic, perinatal, and neonatal factors with school-age outcomes (Taylor, Doyle #2), we propose the following non-neuroimaging variables will be used in model development; other variables may be considered.
  - Center
  - Gestational age
  - Race
  - Gender
  - Multiple gestation
  - Maternal education level (at baseline)

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

- [SUPPORT treatment group]
- Sepsis or meningitis
- NEC
- BPD
- Postnatal steroids
- ROP stage III or more severe
- Length of initial hospital stay (EGA adjusted, i.e., PCA at discharge)
- Any surgery during initial hospitalization

Sample size and power analysis (Primary Hypothesis):

- The sample sizes in the table below are based on formulae for two correlated ROCs (e.g. two ROCs based on the same sample). According to the discussion in the protocol above, we assume that around 370 infants will be available for the 6½ - 7½ year IQ evaluation, assuming ~20% loss to follow-up between 18-22 months and school-age. For a two-tailed test at the 0.05 level of significance and assuming the lowest area under the ROC curve (AUC) for the MRI and the CUS is 75%, an even more conservative estimate of 350 children would produce the powers in the table below for an array of detectable increases in the AUC and prevalence of outcome.

POWER FOR SELECTED INCREASES FROM 75% IN THE AUC OF THE ROC AND PREVALENCES OF THE PRIMARY OUTCOME:
SAMPLE SIZE = 350

AUC Inc. / Outcome P	5%	6%	7%	8%	9%	10%
20%	31%	43%	55%	67%	77%	86%
25%	37%	50%	64%	76%	85%	92%
30%	42%	56%	70%	81%	90%	95%

Hence, if the prevalence of the primary outcome is as low as 20% a conservative sample size of 350 would identify an AUC increase of 10% with reasonable power (86%); if the prevalence is 30%, the detectable increase would be 8% (with power 80%).

Budget: The costs of this proposed follow-up study would span over several years. The first enrolled patient will reach the 6th birthday on 05/10/2011, thus the first window will open 11/10/2011. **It is estimated that 6½ - 7½ year follow-up windows will extend from November 2011 to late 2016.** A range of costs for some subcategories has been provided for loss to follow-up rates between 18-22 months to 6 ½ - 7 ½ years of 10% - 20%.

- Tracking: Similar to the Extended Follow-up of the Hypothermia Trial, tracking will be critical to ensure the best possible follow-up. **Tracking tools and forms have already been developed and launched. RTI is sending tracking reminders to sites.** Because of the importance robust school-age follow-up rates, considerable

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

funds have been budgeted for tracking contacts. The following are suggested contact schedules, although each site will implement specific tracking and contacts appropriate for their patients:
  - Between 18-22 month and 3-4 years: <u>at least</u> 2 phone or other family contacts/ tracking events
  - Between 3-4 years and 6½ - 7½ years: <u>at least</u> 4 phone or other family contacts/ tracking events
  - **$420 per child has been budgeted for tracking.** Release of tracking funds will be contingent on completion of the SEF01 form (tracking form for 18-22 month to 3-4 year contacts).
  - **Total: $155,400 – $174,300**
- <u>Consents</u>: Consent to contact families for possible 6½ - 7½ year follow-up is currently being sought at the 18-22 month visit. Tracking will then commence as noted above. Formal signed consent will be obtained for the majority of the cohort at the time of the 6½ - 7½ year follow-up visit. It is expected that the consent process will take ~1/2 hour (@$35/hour).
  - 14 patients had already been seen in 18-22 month follow-up prior to Dr. Higgins' announcement to NRN site PI's and Follow-up PI's to request to maintain contact. These patients will require some additional time for tracking/consent. We expect that the consent process will take ~1 hour in these cases (@$35/hour).
  - **Total: $6475-$7263**
- <u>Local MRI read:</u> We estimate that relatively little time (~1/2 hour per MRI x $35/hour) will be required to print out/copy final local MRI report, black out patient identifiers, and write in Center number and subject number. These documents will then be sent to RTI.
  - **Total: $9275**
- <u>Training and assuring reliability:</u> The first enrolled SUPPORT Neuroimaging cohort patient will reach the extended follow-up window opening in November 2011. However, there are just 10 patients in the first "wave" with the majority of patient windows not opening until February 2012. Furthermore, given the length of the SUPPORT trial, the final enrolled patients will have 6½ - 7½ year follow-up windows that extend to late 2016. Thus, the total cohort follow-up period will span approximately 5 years. To ensure ongoing training and achieve the best possible reliability for the primary outcome measure (WISC-IV), the following training and reliability assessments have been determined:
  - Training sessions: We propose adding another WISC-IV training session for all sites midway through the follow-up (late 2013 or early 2014). As with the Extended Hypothermia Follow-up, these training sessions will also include training in other components of the follow-up exam, including the NEPSY-II and PEDI. 15 sites are participating in the SUPPORT Neuroimaging secondary, but the 15th site (Emory) will not have patients reaching the 6th birthday until after 2013. We have also added incrementally to the cost per site in 2013 to adjust for inflation.
    - First training session (Fall 2011): $3200 x 14 sites =$44,800
    - Second training session (late 2013): $3400 x 15 sites =$51,000
  - Reliability assessment: In response to Protocol Review Subcommittee comments, we propose ongoing routine exam taping to be sent from

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

participating sites to one of two GOLD STANDARD WISC-IV psychologists. After training and subsequent certification by one taped exam on a non-study patient, the first 3 exams from each site be taped and sent for review and comment, then approximately every 10th exam. This approach will necessitate a DVD recorder to be purchased by each site. We estimate that 3 hours will be required to review and comment upon each WISC-IV exam at $60/hour. Gold standard psychologists will assure that turn-around for comments on these exams be rapid so that sites can incorporate feedback in subsequent scheduled patients' visits. Thus, the budget would reflect the following:

- DVD recorders for each site: $350 x 15 sites = $5250
- Review and comment on certification exam =
  - 1 x 15 sites x 3 hours x $60/hr = $2700
- Review 1st 3 exams from each site =
  - 3x15 site x 3 hrs x $60/hr = $8100
- Review of every 10th exam: Dependent on follow-up numbers:
  - Approximately 30 additional exams x 3 hrs x $60/hr = $5400

- **Total = $117,250**

- 6½ - 7½ year visit costs:
  - $1200 per child has been budgeted for the study visit
  - **Total = $444,000-$498,000**

TOTAL BUDGET ESTIMATE: $732,400 - $806,088 *plus RTI costs*

Thanks Qing! I will probably be getting back to you the week of October 19th with some outlines since I will be on clinical service in the intensive care unit for the next week.

Thanks

Susan

Subject: Abstracts - SUPPORT and Hypothermia neuroimaging

Hi Rose and Abhik

You both know that the cranial US readings for the SUPPORT neuroimaging cohort are almost done (the final CUS will be read by Tom in Detroit at the end of October). So, I think there will be time for analysis for those studies by late breaker deadline. This will be a unique group in that they are all <28 weeks, US have been obtained at specific times, they are centrally read, and perhaps most importantly, we will be able to report progression of abnormalities with respect to clinical factors and randomized SUPPORT treatment groups.

As you also know, we got delayed in the SUPPORT MRI readings delayed due to the Hypothermia readings. Although we are charging ahead and have already sent Kris back about 100+ completed MRI's, the SUPPORT MRI readings are very complex and very time-intensive. As Abhik has said, it may be difficult if not impossible to get all reading done and analysis done for an abstract by February 24. Don't get me wrong - I am still pushing to make it. Pat and I have been meeting at all hours to read, and I have 6:30 am MRI reading times booked with Pat 3x/week! But, I am suggesting that the analysis may be quite complicated, and we should also be thinking about cranial US analysis as a separate abstract. **Rose, do you think the cranial US analysis would be a valuable PAS late breaker on its own?**

The Hypothermia MRI's analysis should definitely be planned for late breaker - this is important, more detailed MRI information than has been previously reported, and I think could go a long way toward better characterizing potential injury pattern differences in cooled vs non-cooled babies. The neonatology community will be excited to hear this valuable information!

Just sharing my thoughts at the moment - thanks. Input welcomed!

Susan

Hi,
We are missing a few SUPPORT outcomes - The final date for data transmission is October 20.

thanks for all the help

Rose

ROP queries 09OCT09.zip
Infants with missing outcomes 09OCT09.xls

Rose,

The ROP queries are attached, in the zipped file. I have also attached a summary of the queries and the usual missing data reminders for the week.

I am also about to re-run the cross-form queries so that the centers can be reminded for queries that are still outstanding. We will send those out on Monday.

Thanks,
Marie

NO, we can go with what we have – the manual states that we will determine status at 55 weeks, so we are likely to have many that we can't assign an outcome.

Thanks, Rose. I will query those with "mature" eyes that still have ROP recorded. Do you think any queries are necessary for those who had two consecutive exams with vessels in zone 3 but still have ROP recorded in that eye?

If an eye is "mature" the ROP should have resolved.

For the infants who still have a pending status at 55 weeks, if we have a normal exam subsequent to the 55 week exam, then we know that they did not have threshold ROP or surgery so could potentially be classified.

Thanks
Rose

Subject: RE: ROP question

Hi all,

In response to my message below, Neil said that it might be an issue if infants who reached final status by having two exams with vessels in zone 3 still have ROP. So, I have summarized the cases where there was either an exam with mature vessels or two consecutive exams with vessels in zone 3 but the final exam still has some degree of ROP.

Infants with an exam with mature vessels that still show ROP in the "mature" eye:
Stage 1 ROP: 2
Stage 2 ROP: 2
Stage 3 ROP: 1

Infants with two consecutive exams with vessels in zone 3 where the last exam still shows ROP in that eye:
Stage 1 ROP: 54
Stage 2 ROP: 13
Stage 3 ROP: 6

Please let me know as soon as possible if any of these cases need to be queried. I can ask the centers to confirm that there was still ROP by entering an F5 on the SUPP10 and/or ask that they find out if there were subsequent exams with no ROP. The queries are basically ready to go out other than this final issue.

Thanks,
Marie

Subject: ROP question

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

Hi all,

I am trying to finalize the ROP queries to go out this week and I have a question. If an infant meets our criteria for final ROP status by having two exams with vessels in zone 3, is it a problem if one of those exams also has stage 3 ROP? If it is, I can query cases we have that are like that.

Thanks,
Marie

Summary of ROP queries (can be >1 query per infant)

The FREQ Procedure

Query		
Query	Frequency	Cumulative Frequency
Multiple ROP exams were entered on SUPP10 for the same date.	13	13
Per SUPP10 left eye had two exams with vessels in zone 3 but the last exam had stage 3 ROP.	6	19
Per SUPP10 right eye had two exams with vessels in zone 3 but the last exam had stage 3 ROP.	5	24
On SUPP10 exam left eye had mature vessels but also had ROP.	5	29
On SUPP10 exam right eye had mature vessels but also had ROP.	6	35
On SUPP10 exam highest ROP stage in lowest zone is > highest stage in any zone.	14	49
On SUPP10 exam lowest zone is '5=Post laser/cryo' but highest stage is not '6=Post laser/cryo'	3	52
On SUPP10 exam left eye meets criteria for Threshold ROP per MOP but Threshold not ='Y' on form.	66	118
On SUPP10 exam right eye meets criteria for Threshold ROP per MOP but Threshold not ='Y' on form.	65	183
On SUPP10 exam left eye does not meet criteria for Threshold ROP per MOP but Threshold='Y' on form.	17	200
On SUPP10 exam right eye does not meet criteria for Threshold ROP per MOP but Threshold='Y' on form.	15	215
Per SUPP10 ROP reached stage 3 in one eye but only stage 1 or no ROP in the other eye.	7	222
Per SUPP10 surgery for ROP was performed in only one eye.	7	229
Per SUPP10 infant had stage 4 or 5 ROP without a previous exam showing threshold ROP.	6	235
Per SUPP10 one or both eyes went from stage 2 or 3 ROP to mature within a week.	3	238
Per SUPP10 infant had exam with mature vessels followed by an exam with stage 3 ROP in zone 1.	1	239
Per SUPP10 infant had 2 exams with vessels in zone 3 followed by an exam with surgery for ROP.	1	240
Per NG03 ROP was diagnosed but ROP is not entered on SUPP10 exams.	14	254
Per NG03 left eye reached a higher stage of ROP than is reported on the SUPP10 (pre-2006).	13	267
Per NG03 right eye reached a higher stage of ROP than is reported on the SUPP10 (pre-2006).	10	277
NG03 left eye exam results do not match any of the exams entered on SUPP10 (pre-2006).	1	278
NG03 right eye exam results do not match any of the exams entered on SUPP10 (pre-2006).	3	281
Per NG03 left eye had threshold ROP diagnosed but that is not reflected on the SUPP10 (pre-2006).	4	285
Per NG03 right eye had threshold ROP diagnosed but that is not reflected on the SUPP10 (pre-2006).	4	289
Per NG03 left eye had surgery for ROP but that is not reflected on the SUPP10 (pre-2006).	1	290
Per NG03 surgery was performed for ROP but that is not reflected on the SUPP10.	2	292
Per NG03 stage 3 or worse ROP was diagnosed but that is not reflected on the SUPP10.	1	293
Per NG03 plus disease was diagnosed but that is not reflected on the SUPP10.	2	295
Per NG03 final ROP status was 2='severe ROP' but that is not reflected on the SUPP10.	1	296

Can you tell us if this looks ok?

I think the NRN PI's may have trouble with the order with respect to Rochester, Miami and Wake given the low numbers recruited in the study. Further, Wake was delayed getting IRB approval and Miami never went back to their IRB after the trial was restarted in 2006 as they knew they were no longer going to be in the network.

Numbers on infants enrolled and eligible by center are attached. Note that I calculated the numbers in two ways. First, I looked at infants who met the SUPPORT inclusion criteria (inborn, 24-27 weeks GA, to receive full resuscitation, and no known major congenital malformations). Second, I looked at those who were "eligible" by subtracting those who met exclusion criteria (born during a time when personnel and/or equipment were unavailable) from those who met inclusion criteria. (In 119 out of the 125 cases where exclusion criteria were met it was because personnel were not available.) The numbers are similar for most centers, but there is a difference for a few, most notably Brown. I will leave it to others to decide

Sent: Tue Oct 06 14:04:20 2009
Subject: RE: SUPPORT Ventilation and Oximetry papers | Author list and boilerplates

Rose,

The numbers in the spreadsheet appear to come from the latest monthly report where the number eligible is calculated as described in the footnote:

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

Eligible GDB patients are those keyed in the NG02 (inborn and GA of 24 0/6 & 27 6/7) with a birth date after the first Support patient keyed for sites at each Center and not born on or between dates of Support study suspension 11/23/2005 and 2/5/2006.

As we have discussed before, these numbers do not match the numbers of infants on the SUPP02 which was supposed to be completed for "all inborn infants with a gestational age of 24 0/7 to 27 6/7 weeks gestation by best obstetrical estimates and who are to receive full resuscitation" and which captures additional eligibility information. I would be inclined to use the SUPP02 numbers, but what do you think?

Thanks,
Marie

Hi Neil and Wally,

Attached are two files, one for the Ventilation and one for the Oximetry papers, with the authors lists and boilerplates. The boilerplates are identical for both papers. The author lists have a few variations for the Yale and Cincinnati authors, as well as switching your names around. Author affiliations are included as footnotes. If you need me to copy these into your drafts, please send the drafts to me.

ABSTRACT

Background: Guidelines for prevention of vertical transmission of Group B Streptococcal (GBS) disease have successfully reduced early-onset GBS disease. Several studies have suggested *Escherichia coli* is emerging as an early-onset sepsis (EOS) pathogen.

Objective: To determine current rates of EOS, associated pathogens, morbidity and mortality of infected newborns.

Design/Methods: Infants with EOS were identified by surveillance at centers of the NICHD Neonatal Research Network (NRN). EOS was defined by a positive blood culture obtained within 72 hours of birth plus antibiotic therapy for ≥5 days (or death <5 days/intent to treat). Maternal risk factors, intrapartum antibiotics, severity of neonatal illness, treatment and outcome were studied.

Results: Among 302,165 live births (2006-2008), 340 infants developed EOS (1.13 cases/1000 LB). Infection rates were inversely related to birth weight. GBS (37%) and *E. coli* (26%) were most frequently isolated. The majority of infants with GBS were term (71%); 81% with *E. coli* were preterm. Overall, 72% mothers had ≥1 risk factor for EO GBS, but only 53% received intrapartum antibiotics (66% preterm, 38% term). Placental pathology was performed for 63% cases, with histologic chorioamnionitis in 73%. While 74% infants required intensive care (96% early preterm, 78% late preterm, 53% term), 24% term infants were asymptomatic and treated in the term nursery. 15% infected infants died, most commonly preterm infants (24%) and those infected with *E. coli* (32%).

Conclusions: In the era of intrapartum antibiotic prophylaxis to prevent transmission of GBS, rates of EOS are low. GBS remains the most frequent pathogen for term infants and *E. coli* has emerged as the most significant pathogen for preterm infants. Missed opportunities for prevention of GBS remain. Prevention of *E. coli* sepsis, especially among preterm infants, remains a challenge.

INTRODUCTION

Neonatal sepsis continues to be a serious problem among newborn infants. In the 1970's Group B streptococcal infections emerged as the leading cause of early-onset neonatal sepsis (EOS) and meningitis.[1] Prevention strategies to reduce vertical transmission of invasive GBS disease based on intrapartum chemoprophylaxis in at risk women (risk-based and screening-based) resulted in substantial reduction in early-onset (EO) GBS disease.[2,3] In an attempt to further reduce rates of EO GBS disease, the Centers for Disease Control and Prevention (CDC) recommended universal antenatal screening and intrapartum chemoprophylaxis for GBS positive women.[4] A further reduction in invasive GBS disease was reported following publication of these revised guidelines in 2002,[5] but missed opportunities for prevention remain.[6]

The epidemiology of neonatal sepsis is a changing landscape.[7,8] In the past decade, several studies have reported the emergence of *Escherichi coli* as an important cause of EOS, particularly among preterm infants.[9-14] Continued surveillance to monitor changes in pathogens associated with infection as well as changes in disease severity and outcome is important as we consider optimal prevention and treatment strategies. This study extends our earlier work on EOS among VLBW infants to all infants born at centers of the Eunice Kennedy Shriver National Institute of Child Health and Human Development (NICHD) Neonatal Research Network (NRN)--a cohort of approximately 100,000 live births (LB) per year.

METHODS

Prospective surveillance for EOS and/or meningitis was conducted among LB infants of all gestational ages (GA) and with birthweight (BW) above 400 g who delivered at one of 16 NRN centers, February 1, 2006–December 31, 2008. EOS and meningitis were defined by isolation of a pathogen from blood (BC) or cerebrospinal fluid (CSF) cultures drawn within 72 hours of birth and antibiotic treatment for ≥5 days (or death <5 days/intent to treat). Cases were identified by research team review of patient, microbiology, or infection control/hospital epidemiology records.

Detailed maternal intrapartum and newborn information was collected including maternal screening for GBS and colonization status, intrapartum antibiotic (IAP) use within 72 hours prior to delivery, maternal risk factors for EO GBS, clinical and histologic chorioamnionitis. Risk factors for GBS sepsis included previous infant with GBS infection, maternal GBS bacteriuria, intrapartum fever (>100.4°F), delivery <37 weeks gestation, and ROM ≥ 18 hours prior to delivery. Neonatal information included infecting organism, antibiotic therapy initiated from birth through day of life 7, severity of illness, and outcome (death, discharge home, transfer). Antibiotic resistance data were collected on isolated pathogens if available from hospital microbiology records.

Statistical analysis

Cultures with growth of Micrococcus, Propionibacterium, or diphtheroids were considered contaminants. Cultures positive for coagulase-negative staphylococci (CoNS) were considered contaminants based on the attending physician's judgment and decision to discontinue antibiotics

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

before day 5 in a surviving infant. Site variation in interpretation of CoNS cultures was examined. Infants with cultures positive for organisms considered to be contaminants were excluded from remaining analyses.

Maternal and neonatal characteristics of infants with early-onset infections were compared among early preterm (22-33 wks GA), late preterm (34-36 wks GA), and term (≥37 wks GA) infants. Maternal and infant antibiotic use was described, with emphasis on infants with *E. coli*, GBS, and CoNS. Infants were defined as symptomatic if they required intensive care or blood pressure support in the first 72 hours of life, or had respiratory distress, apnea, neutropenia (absolute neutrophil count<1000) or thrombocytopenia (platelet count<100,000).

Statistical significance for unadjusted comparisons of categorical variables was determined by chi-square tests and for adjusted comparisons using the Mantel-Haenszel method. EO infection rates were estimated as the number of infants diagnosed with EOS and/or meningitis divided by the total number of live births >400 grams BW during the study period. BW-specific rates were calculated using the number with EO infection and number of live births by BW group (401-1500 g, 1501-2500 g, >2500 g).

RESULTS

Between February 1, 2006 and December 31, 2008, 503 infants born at NRN hospitals had a positive blood and/or CSF culture in the first 72 hours of life. Among these, 163 infants were excluded from further analyses because the organism isolated was considered a contaminant; thus 340 infants were diagnosed with EOS and/or EOM. Coagulase-negative staphylococci were most frequently judged to be contaminants. Overall, 135 infants had a single early culture positive for CoNS (128 blood and 7 CSF cultures), of which 92 isolates (68%) were considered contaminants. Differences in interpretation of a single culture positive for CoNS exist across centers, although numbers at each center are small (Figure 1).

Early-onset sepsis rates

Among 302,165 infants born at NRN hospitals (2006-2008), 340 infants were diagnosed with EOS/EOM, for a rate of 1.13 cases per 1000 live births (range across study centers: 0.33-3.85 cases per 1000 infants, Figure 2). Infection rate was highest among infants 401-1500 g BW and lowest among those >2500 g (Table 1). Pathogens associated with infection changed with BW. Rates of infection with both *E. coli* and GBS were highest among VLBW infants and decreased with increasing BW. Rates of *E. coli* infection were higher than rates of GBS infection among VLBW infants (5.31 vs. 2.10) and LBW infants (0.49 vs. 0.38), while among infants >2500 g, GBS rates were higher than rates of *E. coli* (0.35 vs. 0.08).

Infant cultures and pathogens

While all infants had at least one BC performed (20% single BC, 48% 2 BCs, 32% >3 BCs), only 222 (65%) infants had a lumbar puncture (LP). Likelihood of an LP increased with increasing BW (401-1500g--48%; 1501-2500g--61%; ≥2501g--80%). Of note, 74% infants were being treated with antibiotics when the LP was performed, with a median time of 1 day between

the blood and CSF cultures. Only 13/340 infants (4%) had a pathogen isolated from CSF; 6 of these infants had a negative BC (2% of all infants).

The most frequent EOS pathogen was GBS (37%) followed by *E. coli* (26%) and CoNS (13%, Table 2). No infections with methicillin resistant staphylococci or vancomycin resistant enterococci were identified. Eleven infants had polymicrobial infections (10 blood/one CSF). *E. coli* was the pathogen most frequently isolated from CSF (42%). All infants with *E. coli* in CSF also grew *E. coli* in blood. Among 146 early preterm infants (22-33 w), *E. coli* was the most frequent pathogen found in blood (43%) and in CSF (67%). Among 27 late preterm infants (34-36 w), 33% had GBS in blood, 26% had CoNS, and 19% had *E. coli*. GBS was the most frequent organism among term infants (57%). *E. coli* was the most frequent pathogen found in blood (46%) and CSF (67%) cultures for VLBW infants, 401-1500g BW, and the most frequent blood pathogen for LBW infants 1501-2500g BW (27%, no LBW infants had a postive CSF), while GBS was the most frequent pathogen found in blood for infants >2500 g BW (57%).

Antibiotic Resistance

78% of 79 *E. coli* isolates tested were resistant to ampicillin, 5% were resistant to gentamicin, and 4% were resistant to 3rd generation cephalosporins. Ampicillin resistance was more common among infants whose mothers received intrapartum ampicillin (87%) than among those whose mothers did not (68%, p=0.055). All 78 GBS isolates tested were sensitive to penicillin, ampicillin, and vancomycin. Of 36 GBS isolates tested, 22% were resistant to clindamycin. All 43 CoNS isolates tested were sensitive to vancomycin, but 54% were resistant to oxacillin and 21% were resistant to gentamicin.

Infant antibiotic therapy

Ampicillin and gentamicin were the antibiotics most frequently started for presumed early infection (Table 3); 21% infants were treated with cefotaxime, with highest use among infants with *E. coli* (49%) and other gram negative infections (44%). 18% were treated with vancomycin, with highest use among infants with CoNS (47%) and other gram positive infections (26%). Infants with *E. coli* and CoNS infections were more likely to have a change in initial empiric antibiotic therapy, with exposure to 3 or more drugs for treatment of their early-onset infections (*E. coli*=75%; CoNS=58%; GBS=29%).

Maternal and infant characteristics and risk factors for GBS and E.coli EOS

Over half of mothers of infants with early infections (53%) received intrapartum antibiotics, with the proportion highest among mothers of early preterm infants (Table 4). Overall, 62% mothers were screened for GBS. Despite current CDC recommendations for universal screening, only 67% mothers who delivered at term had been screened for GBS; screening was less common for women delivering preterm (58%). Among those screened, 27% were colonized with GBS, with no difference in colonization rates by GA. Among term infants, the percent of mothers treated with IAP was higher in those who screened positive for GBS, but overall only 73% of those with GBS colonization received IAP. The proportion of mothers who received antibiotics increased with increasing duration between admission and delivery: <4 hours, 38%; 4-24 hours, 48%; >24

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

hours, 66%; p<0.001. Prophylaxis for GBS, suspected chorioamnionitis, and fever were the most common reasons for administration of antibiotics intrapartum. Ampicillin (36%), gentamicin (19%), erythromycin (11%), and penicillin (9%) were the most commonly administered antibiotics, Table 5.

The majority of infants with GBS were term (71%), while the majority of infants with *E. coli* were preterm (81%) (Table 6). Infants infected with GBS were more likely than infants with *E. coli* to be Black (51% vs 30%). Overall, only 55% of mothers whose infants developed EO GBS were screened for GBS (59% term, 46% preterm) and of those who were colonized, only 55% received IAP. In our cohort of infected infants, 78% of term and 25% of preterm infants with EO GBS had a negative maternal GBS colonization screen.

Among preterm infants, the proportion of mothers who had an elevated temperature, uterine or abdominal tenderness, and foul smelling vaginal discharge or amniotic fluid in the 72 hours prior to delivery was higher for mothers of infants infected with *E. coli* than for mothers of infants with GBS infections, although differences were statistically significant for maternal temperature only. Chorioamnionitis was more frequently documented in the medical record for mothers of infants with *E. coli* than with GBS (55% vs. 36% overall, adjusted p=0.054). After adjusting for GA group, no differences were found in the proportion of infants with GBS and *E. coli* whose mothers had placental pathology performed or histologic chorioamnionitis documented. Among women with chorioamnionitis recorded in the medical record, 77% had placental pathology performed. Of these, histologic chorioamnionitis was documented for 90%.
Mothers of early preterm infants were more likely to have placental pathology (84%) compared to mothers of late preterm (58%) or term (44%) infants. Histologic chorioamnionits was documented more frequently for mothers of early preterm infants (80%) than for mothers of late preterm (60%) or term (64%) infants.

Clinical Care and Outcome

Given that more infants with *E. coli* were preterm, it was expected that a higher proportion of infants with *E. coli* received intensive care (90%) compared to those with GBS (64%) or CoNS (67%) (Table 7). Among infants who received intensive/intermediate care, a greater proportion of those with *E. coli* infections had respiratory distress and apnea compared to infants with either GBS or CoNS; however, among preterm infants the proportion with respiratory distress was similar for infants with *E. coli* (95%) and GBS infections (94%) while for infants with CoNS the proportion was lower (76%). Blood pressure support was most likely to be given to infants with *E. coli* and least likely for infants with CoNS. A lower proportion of infants with CoNS had neutropenia (11%) than did infants with GBS (25%) or *E. coli* EOS (34%). Thrombocytopenia was most common among infants with *E. coli.*

While the vast majority of infants with EOS/EOM survived to discharge, 15% died. Mortality and timing of death varied by GA and BW, p<0.001 (Table 8). The proportion of infants who died <3 days of life was highest for infants born at the lowest GA and BW. More infants with *E. coli* EOS died (32%) compared to infants with GBS (11%) and CoNS (5%). However, among preterm infants, the proportion of infants with *E. coli* infection who died was closer to the proportion with GBS who died (37% vs. 31%).

DISCUSSION

The epidemiology of EOS is a changing landscape. Studies over time have demonstrated changes in the predominant organisms associated with infection.[7-9] National guidelines to prevent vertical transmission of GBS disease based on intrapartum antibiotic prophylaxis in at risk women (GBS screen positive or risk factors for GBS in non-screened women) have been a great success.[5,6,15] Our study confirms that in the era of intrapartum chemoprophylaxis, overall rates of EOS are low (1.13/1000 live births). GBS remains the most frequent EOS pathogen, especially for term infants. Missed opportunities for prevention of GBS continue, including failure to screen all women who deliver at term, unknown colonization status of many women who deliver preterm infants, false negative GBS screens among some women who deliver infants with GBS infection, and failure to treat all women who are known to be colonized with GBS. Creative strategies will be needed to increase adherence to prevention guidelines and further reduce EO GBS cases among term and preterm infants.

Several studies have documented increased rates of *E. coli* infection among preterm infants in recent years [8,9] This prospective surveillance study of over 300,000 live births confirms that *E. coli* has emerged as the most frequent EOS pathogen among preterm infants and that infants with *E. coli* infections are at highest risk of severe disease and death. Prevention strategies for early-onset *E. coli* disease need to be developed and tested. Similar to what has been done with GBS, analysis of risk factors associated with EO *E. coli* will be useful to identify high risk women to target for prevention.

Bacteremia is a known risk factor for neonatal meningitis.[16] In our cohort, only two thirds of infants with EOS had an LP performed. More term infants underwent an LP, in large part because VLBW preterm infants are often considered too unstable to tolerate an LP. Although most CSF cultures were negative, 74% infants had their LP performed after initiation of antibiotics, potentially sterilizing an infected CSF and making a diagnosis of meningitis more difficult. Although the number of infants with a positive CSF culture in the face of a negative blood culture was low, these cases are a reminder that meningitis will be missed in some infants if an LP is not part of the sepsis work-up.

The importance of CoNS as EOS pathogens remains unclear. In our cohort, over half of early blood cultures positive for CoNS were judged to be contaminants, with wide center variability in assessment of a single BC positive for CoNS. Although mortality was low among infants judged to have a "real" CoNS infection, 67% were treated in the intensive care unit. Prospective studies of the vaginal ecology of pregnant women, vertical transmission of CoNS, as well as continued surveillance for these organisms among newborn infants with EOS will help determine if CoNS are emerging as important EOS pathogens.

Rational choice of antibiotics requires review of antibiotic susceptibility of the predominant organisms causing disease at the local level.[17] Ampicillin and gentamicin continue to be the recommended empiric antibiotics for the infant at risk for EOS.[18] Our study supports this recommendation as all GBS isolates were sensitive to ampicillin and 95% of *E. coli* isolates were sensitive to gentamicin. That said, treatment of the specific infant must be guided by antibiotic susceptibility of the infecting organism and clinical course.

With current neonatal intensive care, the vast majority of infants with EOS survive. The most immature infants and those infected with *E. coli* remain at highest risk of death. Although improved treatment strategies may reduce the current 15% mortality, strategies to reduce the unacceptably high rates of preterm birth in the United States are more likely to reduce deaths associated with early-onset infections, as well as deaths related to other complications of prematurity.

Hi Rose,

Marie pointed out that is might be better to wait until after the 20th because that is the deadline we gave the sites to get data in and we would then need to process any transmissions the night of the 20th to get completely up to date data. Please let me know what you think.
Thanks,
Kris

Hi,

The data was updated last night and processing today; will check with Marie and Dr. Wallace about the date. Do we need the actual reports or in some cases pictures from the all sites to review; if so, it will likely take a week or two to request these, make copies and get them to the folks that are reviewing them, or, are we just talking about the Duke cases?

Thanks,
Kris

Kris
Are you and marie available on the afternoon of october 20 for a SUPPORT ROP call with Dale? If so, can you ask Dr. Wallace from Duke if he can join and we can decide about the cases with unknown outcome. If that day doesn't work, we can try later in the week.

Also, do you have the updated list of the 64 duke patients for them to certify the outcomes?

Thanks
Rose

Subject: RE: case question

ok....just so i'm straight then...if the after 55 weeks exam is the final outcome..should the answer to the question about final status at 55 weeks be 'yes' lost...and the answer to the question about final status determined at 18 months also be 'yes'?

(sorry to bug you about this...but I want to make sure that what we plug in is correct)

If the exam was done after discharge, the GDB outcome is undetermined. However, for SUPPORT, we can use the exam after 55 weeks for final outcome (we know that some of them become final as late as 7-8 months). Enter the date of the exam and the exam results as fully mature and this should suffice as a 'determined" SUPPORT outcome.

Thanks
Rose

Cc: Phelps, Dale; Ronald N Goldberg; Kimberley A Fisher; Zaterka-Baxter, Kristin; David K Wallace
Subject: RE: case question

Hi again Rose and team (including David Wallace this time)...another tough one to call (the last one re-reviewed actually of the 64 at Duke..)...case number 72421, another one with exam at 45 weeks pma, the 8th exam in a row of stage 2, zone 2 bilaterally.....again exam by David,,,,,next exam is scheduled for '1 year later' but is seen 4 months later (after 55 weeks), w/ stage 0, zone 4 fully vascularized....

would this one be a 'yes' to final status lost to followup at 55 weeks? I think it would be a yes....but again, David W's take on what's a favorable outcome (or definite enough at 45 weeks to allow a big window til next exam that then occurs after 55 weeks) is different from the listed outcomes in the MOP...

for reference here's David's response on the similar case:

"There are 4 reasons to stop screening, and this child had #3 and #4.

Here is the excerpt from the AAP/AAO screening guidelines paper:

(Embedded image moved to file: pic60036.gif)
I don't suggest changing an outcome, but there could be a clarification that any of these 4 meet criteria for "favorable status."

and the MOP:

15.2 Acute/final Status
An eye is 'acute/final" when it reaches one of the following points in time:
These can be a good outcome (favorable) as the ROP heals (regresses), or it can be the

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

primary outcome variable event (unfavorable).
Favorable
* Vessel growth if mature to the ora serrata in all clock hours
* Vessels in zone III for two sequential eye examinations
(i.e. two examinations in a row)
Unfavorable
* type I threshold ROP
* Laser (or cryo or both) surgery for acute ROP
* retinal detachment stage 5 retinal detachment stage 4b
Other
* Infant dies.

so it's confusing..because if ophthalmologists then scheduled visits well beyond 55 weeks and its w/in their standard of care to do so....not sure if a site (ours and maybe others???) can be at fault w/ a 'missing outcome' if the baby wasn't back in that 10 week window between 45 and 55 weeks....

Subject: NEOProm meta analysis of oximetry trials

Hi,

Lisa Askie, who is leading the prospective meta analysis of the oximetry trials for which we are participating from the SUPPORT Trial is asking for birth order and sibling match to be included in the final data set. We do have information on birth order and sibling match in our data; however, there is a question of whether we can share that information due to privacy issues. For example, if there is a set of quadruplets that might be a rare enough occurrence that sharing the information would make the infants identifiable. There is the additional complication that cases of multiple births in SUPPORT were randomized as a group (the pregnancy, not the infant, was the unit of randomization).

Please let me know if you are able to share this information on patients in the study of potentially triplets or even higher order multiples for the individual patient meta analysis. If you need to consult your IRB, please do so.

Please send me a response by October 23.

Thanks
Rose

ABSTRACT

Background

Non randomized studies suggest that the incidence of retinopathy decreases in premature infants with exposure oxygenation levels lower than previously maintained. However, the range of oxygen saturations that reduces retinopathy without increasing adverse outcomes is not known.

Methods

1316 infants of 24 to 27 weeks gestation born at 20 centers of the NICHD Neonatal Research Network were randomly assigned at birth to oxygen saturation targets of 85 to 89% or 91 to 95%. The primary outcome was a composite of threshold retinopathy of prematurity, eye surgery for retinopathy, and/or death. As part of the SUPPORT Trial, infants were also randomized to continuous positive end expiratory pressure with permissive hypercapnia or to intubation and surfactant.

Results

Conclusions

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

INTRODUCTION

Retinopathy of prematurity remains an important cause of blindness and other visual disabilities in prematurely born infants. The incidence of retinopathy of prematurity increased with exposure to unrestricted oxygen in premature infants in randomized controlled trials performed in the 1950s.[1] However, in subsequent years, the practice of restricting oxygen supplementation was estimated to result in an excess of 16 deaths per case of blindness prevented.[2] More recent data suggest that oxygen saturation levels previously thought to be in the upper limits of normal appear to also increase the risk of retinopathy of prematurity.[3-5] Oxygen toxicity may also increase the risk of mortality[6, 7], bronchopulmonary dysplasia[8-10], periventricular leukomalacia[11], cerebral palsy[12], and other morbidities. Although a multicenter study [13] could not determine an association between oxygen levels and retinopathy, a single center cohort study using transcutaneous oxygen monitoring supported the association of retinopathy with exposure to arterial oxygen levels $\geq$ 80 mmHg.[14]

Pulse oximetry allows clinicians to utilize continuous oxygen saturations to target oxygenation in infants receiving oxygen supplementation. A survey study of 144 neonatal intensive care units conducted in 2001 revealed that the average lower limit of target oxygen saturations was 90% and the upper limit was 96%.[5] In recent years, the use of high saturation targets has been associated with the increased risk for retinopathy. The rate of retinal ablation surgery was higher at neonatal intensive care units with maximal target oxygen saturation $\geq$ 92% (3.3 $\pm$ 0.3 versus 1.4 $\pm$ 0.2%) or $\geq$ 98% (5.6 $\pm$ 1.1 versus 3.1 $\pm$ 0.3%).[5] Oxygen saturation targeting from the first day after birth at levels lower than previously used may reduce the incidence of retinopathy.[3] In a retrospective study comparing outcomes at five neonatal intensive care units, the incidence of severe retinopathy requiring ablation therapy was 27% in units

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

where target saturations were 88 to 98% and only 6% in units where the target was 70 to 90%.[3] Rates of mortality and cerebral palsy did not differ in these units. In three other studies, a policy of oxygen saturation targeting of approximately 83 to 95% resulted in a substantial reduction in retinopathy.[4, 15, 16] However, actual oxygen saturations achieved were not reported. Pulse oximetry has become the standard technique for continuous monitoring of oxygenation. While data from recent prospective observational and retrospective studies[3, 4, 15-19] suggest that maintenance of oxygenation at ranges lower than previously used may decrease the incidence of retinopathy of prematurity, there is no conclusive evidence that these oxygenation levels do so without an increase in serious adverse effects, including the possibility of increased risk of death with lower oxygenation as previously reported.

We conducted a 2 x 2 factorial-design multicenter randomized trial of oxygen saturation targeting and ventilation strategy. The oxygen saturation arm tested the effect of a lower oxygen saturation target range (85-89%) compared to a higher oxygen saturation target range (91-95%) on the incidence of threshold retinopathy of prematurity, eye surgery for retinopathy, and/or death among infants of 24 to 27 weeks gestational age at birth. The ventilation arm of this factorial design trial also allowed us to simultaneously test the effect of prophylactic/early surfactant versus continuous positive airway pressure with a permissive ventilatory strategy on bronchopulmonary dysplasia or death at 36 weeks postmenstrual age (results to be reported separately). The factorial design of the trial effectively controlled for ventilator approaches in the oxygen saturation arm of this trial.

METHODS

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

The institutional review boards at all Neonatal Research Network clinical centers and at Research Triangle Institute International, the independent Data Coordinating Center for the NRN (data center) approved the trial. Written informed consent was obtained from the parent or guardian of each participant before delivery.

Patients

Infants of $24^{0/7}$ to $27^{6/7}$ weeks gestational age, without a decision to forego resuscitation were eligible for enrollment at birth. Exclusion criteria were outborn infants and major congenital anomalies. Multiple births were randomized to the same arm of the trial.

Enrollment and treatment

Deliveries were stratified by center and by gestational age ($24^{0/7}$ to $25^{6/7}$ weeks or $26^{0/7}$ to $27^{6/7}$ weeks). They were randomly assigned by means of double-sealed envelopes to oxygen saturation targeting of 85 to 89% or 91 to 95%. Deliveries were randomized as a unit; thus, multiples were randomized to the same arm of the trial. Masking was maintained using electronically-altered pulse oximeters with output display of 88 to 92% for these oxygen ranges, with an offset of 3% (Massimo Radical Set Pulse Oximeter, Irvine, CA) as previously used to separate oxygen saturations in premature infants.[20] The oxygen saturation values displayed reverted to actual values when less than 85% or higher than 95%, the levels of alarm setting recommendations by protocol. Oxygen saturation targeting with altered pulse oximetry was initiated within the first two hours after birth and was continued until 36 weeks post-menstrual age or until the infant remained on room air and off the ventilator/continuous positive airway pressure for more than 72 hours. Infants weaned to room air but who subsequently received oxygen supplementation before 36 weeks post-menstrual age were placed back on the assigned study pulse

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

oximetry. Adjustments in supplemental oxygen to maintain the target oxygen saturation between 88-92% were performed by the clinicians not by the research staff. For the ventilation arm of this 2 by 2 factorial design trial, participants were also randomly assigned to respiratory support using either prophylactic/early surfactant with conventional ventilation management or to continuous positive airway pressure with a permissive ventilatory strategy.

Assessments

Research nurses recorded all data using standardized definitions. Data were collected until discharge or 120 days postnatal age whichever occurred first. Threshold retinopathy of prematurity (New Type 1 threshold per Early Treatment of Retinopathy [ETROP] Cooperative Group[21]) was coded if any of the following four findings were present up to 55 weeks post-menstrual age:

If in zone 1: Stage 3 retinopathy of prematurity, even without plus disease

Plus disease with any stage retinopathy of prematurity

If in zone II: Plus disease with stage 2 retinopathy of prematurity

Plus disease with stage 3 retinopathy of prematurity

Surgical intervention included laser therapy, cryotherapy, laser/cryotherapy, scleral buckle, vitrectomy, and bevacizumab (Avastin). Outcomes included predefined clinical diagnoses and potential adverse events.

Statistical analysis

The primary analysis for the oxygen saturation arm of this factorial trial was a generalized estimating equation (GEE) model that used robust Poisson regression to produce adjusted relative risks comparing incidence rates for infants in each treatment group (lower versus higher oxygen saturations) who

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

developed the primary outcome. The model produces relative risk estimates adjusted for stratification by center and gestational age as well as for the familial clustering due to randomization of multiple births to the same treatment arm.

An absolute difference of 10% between the two treatment groups was considered clinically important. To detect this difference, we planned to enroll 1310 infants for 80% power to detect a 10% difference in outcome assuming a baseline estimated rate of 50% of death/threshold retinopathy/surgery. This sample size estimate included an increase by a factor of 1.12 to account for randomizing multiples to the same treatment group and on an increase by a factor of 1.17 to account for the expected attrition after discharge and before follow up. While these sample size calculations allowed for the testing of two co-primary outcomes for the two intervention arms (oxygenation and ventilation) of this 2 by 2 factorial trial, the trial was not powered to determine an interaction between the two interventions. Intention-to-treat analyses were performed. The denominator used to calculate the rate of each outcome was the number of infants for whom that outcome was known. All analyses were conducted at the data center. A two-sided P value of less than 0.05 was considered to be statistically significant. Analyses did not include adjustment for multiple comparisons. An independent data safety and monitoring committee appointed by the Director of the NICHD reviewed the primary outcomes, adverse events, and other interim results at ~25%, 50%, and 75% of planned enrollment. Lan-DeMets spending functions with Pocock (O'Brien-Fleming) boundaries were used to develop stopping rules for interim safety and efficacy monitoring. Safety outcomes monitored included death, pneumothorax, intraventricular hemorrhage and a combination of any of the above events.

RESULTS

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

1316 infants were enrolled between January 2004 and March 2009 (Figure 1). Enrollment was temporarily paused after evaluation by the Data Safety and Monitoring Committee (DSMC) and decision of the NICHD Director because of concerns regarding compliance with oxygen saturation targets. Separate analysis of the oximetry data while on room air versus while on oxygen supplementation resolved the concerns, and trial enrollment resumed upon approval by DSMC and NICHD Director decision. The baseline characteristics of the lower saturation group and the higher saturation group were similar (Table 1).

Major outcomes

The Data Safety and Monitoring Committee masked interim analyses for safety were made available to the investigators after initial data analyses (last infant reached 55 weeks corrected age). There had been a trend for increased mortality in one of the treatment groups that had not reached the stopping boundary. The principal investigators and the NICHD and data center staff performed a detailed analysis which uncovered clinically and statistically significant trends with respect to mortality. While acknowledging that the designated primary outcome for this trial is death or retinopathy of prematurity, it was decided not to wait for incoming retinopathy of prematurity outcome data (which will take substantially more time to collect and assess) and report the mortality findings to the practicing neonatal community while the retinopathy of prematurity data accumulate. Retinopathy and 18-22 month follow up outcomes will be reported later.

Mortality at any time during hospitalization occurred in 130 of the 655 (20%) of the infants in the lower oxygen saturation group versus in 106 of the 661 (16%) of the infants in the higher oxygen saturation group (RR 0.78, CI 0.62, 0.99, P=0.04). Comparable results were observed within both gestational age

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

groups used for stratification. Mortality in the first and second weeks after birth was comparable in the two treatment groups (Table 2). Other pre-specified major outcomes were comparable between the two treatment groups (Table 2).

The median oxygen saturation of both groups differed substantially but, as expected, there was some overlap (Figure 2). These data indicate that actual oxygen saturation levels are slightly higher than targets in both treatment groups. The duration of oxygen supplementation was shorter in the lower oxygen saturation group but the duration of mechanical ventilation, continuous positive airway pressure, and nasal synchronized intermittent mandatory ventilation did not differ (Table 3). Other measures of resource utilization did not differ as well.

DISCUSSION

The recommended ranges of oxygen saturation targeting for very preterm infants have been determined from nonrandomized studies and restriction of oxygen supplementation is becoming the standard practice.[3, 22] However, there was an increase in mortality when a restrictive oxygen supplementation was practiced in the 1950s and 1960s. Despite not being based on randomized controlled trials and limited evidence of safety, lower oxygen saturation targeting has been increasingly adopted by units and physicians who are desirous of decreasing significant retinopathy of prematurity. However, in the current trial, lower oxygen saturation targeting (actual 85-89%) resulted in an increased risk of mortality.

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

This trial was not powered for a difference in mortality only between the two oxygen saturation groups. However, this is the largest completed prospective multi-center randomized trial to test the effect of lower versus higher oxygen saturation targeting, and the results add to previous data raising the concern that oxygen restriction may increase mortality in very preterm infants. The infants in this trial were more immature than those of any previous trials of oxygen restriction and, thus, may have had a higher susceptibility to the effects of lower oxygen saturation targeting. In addition, aside from the decreased use of oxygen supplementation at 36 weeks, there were no other benefits from oxygen restriction among the outcomes evaluated. The previous data on the increased mortality from oxygen restriction were from studies with lower levels of evidence rather than from randomized controlled trials. It is interesting and worrisome that the combined risk difference observed in the trials from the1950s was a 4.9% increase in mortality in the oxygen restricted group, which is very similar to the 4% mortality increase in the lower targeted SpO2 group that was observed in our trial.[1]

Restriction of oxygenation in previous randomized controlled trials in preterm infants beyond the first weeks of life did not show trends for increased mortality in the lower saturation target groups.[17, 18] However, these trials aimed for saturations of 91 to 94% and 89 to 94% in the lower oxygen saturation group. Mortality in the current trial did not differ by 7 or 14 days. Therefore, we surmise that the lower target of oxygen saturations rather than the postnatal age of the intervention is related to the adverse outcome.

There are several ongoing trials across the world that address the same intervention tested in the current trial as well as a planned prospective meta-analysis.[1] At the present time, it is important that these trials continue and that the investigators and the data safety and monitoring committees of these trials are

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

aware of the results of the current trial so that appropriate decisions can be made regarding their interim analyses, completion of the trials, and dissemination of the data. The current trial raises the concern of adverse hospital outcomes due to oxygen saturation targeting in the 85 to 89% range. Further information from the ongoing randomized controlled trials that evaluate lower versus higher oxygen saturation targeting will become available in the next years but at the present time, caution should be exercised regarding oxygen targeting in the low range for extremely premature babies, such as those tested in the current trial.

Abstract

Background: The most appropriate initial and ongoing respiratory support for the extremely low birthweight infant (ELBW) has not been established by adequate prospective evidence. The current usual approaches include the early use of continuous positive airway pressure (CPAP) or the early administration of surfactant following endotracheal intubation.

Methods: The SUPPORT study was a randomized multicenter factorial trial that enrolled consented preterm infants of 24 0/7ths weeks to 27 6/7ths weeks by best obstetrical estimate within 2 prospective strata, 24 to 25 6/7ths weeks and 26 to 27 6/7th weeks. Infants were randomized to CPAP initiated in the delivery room and were subsequently treated using a permissive strategy allowing higher PaCO2s and extubation at higher ventilator settings. Infants randomized to surfactant were intubated and received surfactant within 60 min minutes of birth. All infants were also randomized to one of 2 ranges of SpO2 while in the NICU and receiving supplemental oxygen, a low target range of 85% to 89% and a high target range of 91% to 95% using specifically altered blinded oximeters.

Results: The study enrolled 1317 infants from January 1 2004 to March 1 2009. There were 565 infants enrolled in the lower gestational age strata, and 751 in the higher strata. In the delivery room, 66% of the CPAP infants received positive pressure ventilation compared with 93% of the surfactant infants, and surfactant was given to 14% of the CPAP versus 51% of the surfactant group (all p<0.001), and 67% of the CPAP infants received surfactant at any time during their hospitalization,. The primary outcome of death or BPD, defined as the need for supplemental oxygen at 36 weeks post conceptional age was 48% versus 54%, ($p < 0.05$, when adjusted for gestational age, center and familial clustering). There was a significantly lower mortality in the 24 to 25 weeks strata for the infants in the Surfactant arm, (24% vs 32%, p=0.03). There were no differences overall for death in the delivery room nor any differences in length of stay, or days of oxygen for survivors, and the need for oxygen at discharge. More CPAP infants were alive and off mechanical ventilation by day 7, (p=0.015). All infants in the Surfactant arm were intubated, compared with only 77% of the CPAP infants requiring intubation during their nursery course, (p<0.001). There were no differences between the groups for air leaks including pneumothoraces.

Conclusions: The use of early CPAP with a permissive ventilator strategy results in a decrease in death or BPD defined as the need for oxygen at 36 weeks post conceptional age compared with the use of surfactant within 1 hour of birth and a conventional mechanical ventilation approach. There were no increased adverse outcomes in the CPAP group, and the surviving infants will be followed for a complete neurodevelopmental assessment at 18 to 22 months.

Comment [AD1]: Should we rephrase this? Sounds like the infants themselves gave consent!

Comment [AD2]: I would provide the relative risk and 95% CI instead of, or in addition to the p value. Same goes for other CPAP vs surfactant outcome comparisons, both here and in the main text.

Early CPAP and the use of a permissive ventilator strategy is an evidence based approach for the initial respiratory support of the ELBW infant.

Introduction:

At the present time, there is no agreement as to the optimal approach to respiratory support for the extremely low birth weight (ELBW) infant following delivery. Positive End Expiratory Pressure (PEEP) has been shown to be of benefit in maintaining functional residual capacity (FRC), and continuous positive airway pressure appears beneficial during cardiopulmonary resuscitation[1]. Gregory et al in 1971 first demonstrated that the use of CPAP started at approximately 5.9 hours (+12.4hrs) for their infants < 1500 gm at birth, improved oxygenation[2] in newborn infants with respiratory distress; these observations were followed by prospective studies that demonstrated improved survival in premature infants treated with early CPAP[3]. A review of prospective studies evaluating early (not delivery room) CPAP in the pre-surfactant, pre-antenatal steroid era found that early CPAP improved survival overall and for infants greater than 1500 gm, and was associated with increased pneumothoraces.[4] A more recent review of prophylactic CPAP started in the delivery room reviewed only 2 available trials and found no significant difference between the CPAP and conventionally managed infants and noted a trend to increased adverse outcomes for the CPAP treated infants.[5]

There is substantial retrospective evidence suggesting a benefit for early CPAP in experiences from both the US and other countries.[67] These reports have documented a decrease in the need for mechanical ventilation among very preterm infants without an increase in morbidity following the initiation of early CPAP treatment.[8910]

The current available evidence demonstrates that prophylactic and early surfactant treatment at less than 2 hours of life significantly decreases mortality, air leak, and BPD in preterm infants.[1112] Overall surfactant has not been reported to significantly reduce BPD, but may do so for the most immature infants and has not been found to significantly reduce subsequent neurodevelopmental impairment (NDI). [13]

The recent COIN trial randomized 610 infants from 25 weeks 0 days to 28 weeks 6 days gestational age at birth, who were able to breathe at 5 minutes of age and had evidence of respiratory distress at that time. Infants were randomized to either intubation and ventilation

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

or CPAP at 8 cm H20. CPAP infants were intubated if they met failure criteria.[14] This study did not compare early CPAP to the early administration of surfactant, and surfactant use followed unit standard of care. There was a significant primary increase in the occurrence of pneumothoraces in the CPAP group (9.1% vs 3.0%, p=.001), most occurring within the first 2 days, consistent with the findings of an earlier meta analyses~~6~~, and a reduction in death or the need for oxygen at 28 days in the CPAP infants (odds ratio, 0.63; 95% CI, 0.46 to 0.88; P=0.006) with no difference in death or BPD at 36 weeks.

In view of the current interest in the use of early CPAP and the lack of prospective comparisons of this approach with the evidence based intervention of prophylactic or early surfactant, the SUPPORT study was designed to compare these approaches for the most preterm infants. We also randomized infants to 2 ranges of pulse oximetry targets during their exposure to oxygen using a factorial design, and the results for the oximetry study will be reported separately.

Methods

This was a randomized, factorial 2X2 design multi-center trial conducted by the NICHD Neonatal Research Network. This report describes the prospective comparison of CPAP and a permissive ventilatory strategy begun in the delivery room and continuing in the NICU with the early (< 1 hour) intratracheal administration of surfactant followed by conventional mechanical ventilation.

Infants were also randomized to a prospective comparison of a lower SpO2 range (85% to 89%) with a higher more conventional SpO2 range (91% to 95%) until the infant was no longer requiring ventilatory support or oxygen using purpose altered oximeters. These results will be separately reported.

The primary hypothesis of this trial was that relative to infants managed with prophylactic/early surfactant and conventional ventilation that the use of early CPAP and a permissive ventilatory strategy in infants of 24 to 28 weeks gestation with continuing CPAP in the NICU will result in an **increased survival without BPD** at 36 weeks.

Comment [AD3]: We should be consistent in either picking death or BPD, or survival without BPD.

Eligible infants were 24 0/7ths to 27 6/7th weeks at birth by best obstetrical estimate, born at a randomizing center, for which a decision had been made to provide full resuscitation, without known malformations, and for whom parental consent had been obtained. The infants were randomized within each center to 2 gestational age strata, 24 0/7ths to 25 6/7ths weeks, and 26 0/7ths-27 6/7ths weeks.

CPAP Arm - Delivery room management: A T-piece resuscitator, a neonatal ventilator, or an equivalent CPAP methodology was used at all sites for the delivery room administration of CPAP. CPAP or ventilation with PEEP both at a recommended 5 cm H_2O was utilized if the infant required positive pressure during resuscitation. CPAP was continued until admission to the NICU using the T-piece resuscitator or equivalent device and a face mask or nasal prongs. CPAP infants were not to be intubated for surfactant only in the DR, and CPAP infants who required intubation for resuscitation were to receive surfactant within 60 minutes of birth. Intubation for these infants was performed only for the standard NRP indications including failure to respond to positive pressure ventilation (PPV) with evidence of continuing cyanosis or bradycardia, the need for chest compressions, the need to administer intratracheal medications, or other situations in which the resuscitation team determined that surfactant is urgently required.

NICU management: Intubation was performed at any time for the occurrence of repetitive apnea requiring bag and mask ventilation, clinical shock, sepsis, and/or the need for surgery. While intubation was never required by protocol, CPAP infants could be intubated if they met any of the following criteria: an FiO_2 >.50 required to maintain an indicated SpO2 $\geq$ 88% for one hour, an arterial $PaCO_2$ > 65 torr documented on a single blood gas, or hemodynamic instability defined as a low blood pressure for gestational age and/or poor perfusion, requiring volume and/or pressor support for a period of 4 hours or more. If intubated within the first 48 hours of life infants were to receive surfactant.

Extubation for CPAP infants was to be attempted within 24 hours if all of the following criteria were met: a PaCO2 < 65 torr with a pH > 7.20, an SpO2 > 88% with an FiO2 < 50%, a mean airway pressure (MAP) < 10 cm H2O, ventilator rate < 15 bpm, an amplitude < 2X MAP if on high frequency ventilation (HFV), and hemodynamically stable, and without a clinically significant patent ductus arteriosus. Re-intubation criteria were the same as those for intubation. After 3 intubations CPAP infants were treated using NICU standard of care.

Surfactant Arm: All infants were to be intubated within 1 hour of life and receive surfactant, followed by continued ventilation. All infants were to be extubated within 24 hours of meeting all of the following criteria: $PaCO_2$ < 50 torr and pH > 7.30 An FiO2 $\leq$ 35 with a SpO2 > 88%, a mean airway pressure (MAP) < 8 cm H_2O, ventilator rate $\leq$ 15 bpm, an amplitude < 2X MAP if on high frequency ventilation (HFV), and be hemodynamically stable with no evidence of clinically significant PDA. Once extubated Surfactant infants were treated using NICU standard of care.

These criteria were in effect for the first 14 days of life, following which the infant was treated as per NICU standard of care. For both arms of the trial intubation could be performed at any

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

time for the occurrence of repetitive apnea requiring bag and mask ventilation, clinical shock, sepsis, and/or the need for surgery.

Randomization was stratified by center and gestational age group, utilizing specially prepared double-sealed envelopes. Deliveries were randomized as a unit, and thus multiples, were randomized to the same arm of the trial.

Hypothesis and sample size: We hypothesized that early CPAP would reduce the incidence of death or survival with BPD at 36 weeks, (using the NRN occurrence of death or survival with BPD of 67% using the year 2000 data), **and the occurrence of death or survival with neurodevelopmental impairment (NDI) at 18 to 22 months (using the NRN occurrence of NDI of 61% using year 2000 data) by 10%**. We increased the sample size by a factor of 1.12 to allow for multiples to be randomized to the same treatment as this introduced a clustering effect into the design, and increased the sample sizes by a further 17% to adjust for attrition after discharge and before follow-up. This resulted in a sample size of 1312 infants. This sample size was not large enough to determine an interaction effects between the 2 factorial arms.

Comment [AD4]: Since we are not reporting NDI here, and did not adjust our sample size for multiple outcomes, do we need to say this?

In addition there was a prospective decision to also evaluate the occurrence of BPD using the Physiologic Definition which required an attempt at oxygen withdrawal for infants who required < 30% oxygen at 36 weeks and assigned a diagnosis of BPD to any infant who required more than 30% oxygen at 36 weeks or who required positive pressure support. [1516]

Statistical analyses: Intention-to-treat analyses were performed. The denominator used to calculate the rate of each outcome was the number of infants for whom that outcome was known. The primary analyses focused on the percent of each Group who developed their respective outcome measure of survival without BPD at 36 weeks. Adjustment was performed as pre-specified for gestational age, center and familial clustering using robust Poisson regression implemented in a Generalized Estimating Equation (GEE) model to obtain adjusted relative risks. A two-sided P value of less than 0.05 was considered statistically significant. An independent data safety monitoring committee reviewed the interim safety and efficacy results, including those concerning adverse outcomes, four times. Lan-DeMets spending functions with Pocock (O'Brien-Fleming) boundaries were used to develop stopping rules for interim safety and efficacy monitoring. Safety outcomes monitored included death, pneumothorax, intraventricular hemorrhage and a combination of any of the above events.

Comment [AD5]: Let us make the statistical sections of both primary papers as similar as possible.

The study was approved by Human Subjects Committees at all participating sites and RTI, the NRN data center that managed and analyzed all the data, and parental consent for participation in the trial was required before delivery.

Results:

There were 1317 infants enrolled in this trial from Jan 1 2004 through to Mar 1 2009 . The trial was temporarily suspended by the DSMB because of concerns regarding the oximetry data in November 2005 but after a complete review the trial was continued in February 2006 with no protocol changes. The patient descriptive information for the CPAP versus Surfactant arms is shown in Table 1.There were 565 infants enrolled in the lower gestational age strata, and 751 in the higher strata. There were no significant differences for sex, birth weight, Apgar scores or race between the 2 treatment groups. The Surfactant group received significantly more epinephrine in the delivery room and had a trend for higher DR mortality which was not significant.

In the delivery room, 66% of the CPAP infants received positive pressure ventilation compared with 93% of the surfactant infants, and surfactant was given to 14% of the CPAP versus 51% of the surfactant group, and 67% of the CPAP infants received surfactant at any time during their hospitalization, (all $p<0.0001$). Intubation in the DR occurred in 34% of CPAP infants compared with 93% of surfactant infants, $p<0.0001$, Table 2.

The primary outcome of death or BPD, defined as the need for supplemental oxygen at 36 weeks post conceptional age was significantly lower for the CPAP group compared with the Surfactant group, 48% versus 54%, ($p < 0.05$, when adjusted for gestational age, center and familial clustering as prespecified). Death during the hospitalization was 4% lower for the CPAP group overall, and was significantly lower in the CPAP arm for the 24 to 25 week strata. There was a non-significant reduction in the occurrence of BPD using the need for supplemental oxygen, 40% vs 44%, $p=0.27$. Using the Physiologic Definition for BPD there was no decrease in the occurrence of BPD in the CPAP group (40% vs 41%, $p=0.96$), and a non-significant reduction in the occurrence of death or Physiologic BPD at 36 weeks in the CPAP group, (48% vs 51%, $p=0.32$).

There were no differences overall for death in the delivery room nor any differences in length of stay, or days of oxygen for survivors, and the need for oxygen at discharge. (Table 3). More CPAP infants were alive and off mechanical ventilation by day 7, ($p=0.01$). There were no differences between the groups in air leaks in the first 14 days, air leaks during the hospital stay, medical or surgical NEC, PDA requiring surgery, or severe IVH. All infants in the Surfactant arm were intubated, compared with 83% of the CPAP infants who required intubation during their nursery course, ($p<0.0001$). There was a significant reduction in the use of postnatal steroids for BPD in the CPAP infants compared with the Surfactant infants, 7% vs 13%, $p<.001$).

Strata Results: 24 – 25 weeks Gestation

Comment [AD6]: Do we need to preface some justification for looking within strata?

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

There were significantly more non-Hispanic black infants in the CPAP group compared with the Surfactant group. The differences are shown in Table 4 (24-25 wk Strata). CPAP infants had a significantly lower mortality 24% vs 32%, p=0.03. There was a significantly higher exposure to postnatal steroids for BPD, 21% vs 13%, p=0.02 for the Surfactant group, and there were more infants alive and off mechanical ventilation at 1 week in the CPAP infants in this strata.

26-27 weeks Gestation

There was no difference in mortality for the CPAP vs Surfactant groups, 10% vs 11%. The CPAP infants required fewer days of oxygen, 36.8 vs 46.5, p<0.01, lesser days of mechanical ventilation, 10.7 vs 14.2, p<0.01, and less postnatal steroids for BPD, 3% vs 8%, p<0.01.

Discussion:

The SUPPORT trial is the first multicenter trial to compare early CPAP with early surfactant given within an hour of life in ELBW infants. The current trial is the largest study reported to prospectively compare the use of early CPAP and early surfactant for the ELBW infant and the only study to include infants of 24 weeks gestation. In a preliminary study we found that 100% of infants of 23 weeks gestation required intubation in the DR, and thus decided that such infants would be unlikely to be successfully treated with CPAP alone following delivery.[17] Others have retrospectively reported that some of these infants can be successfully managed with early CPAP, but the majority of such infants require intubation.[18]

Our study differs from the recently reported COIN trial[1414] in that we randomized all eligible ELBW infants of consenting families irrespective of whether they demonstrated spontaneous breathing, included infants of 24 weeks gestation and compared the CPAP/permissively ventilated infants with infants who all received surfactant within 1 hour of birth. Our method of using early CPAP and a permissive ventilation strategy was a result of previous retrospective reviews of practice which demonstrated that the unit with the most success using CPAP also utilized a very permissive approach for intubation and the initiation of mechanical ventilation. **Error! Bookmark not defined.**~~8~~ We believed that testing this complete approach would provide a more relevant result as most units currently using early CPAP also tend to be permissive in their use of intubation.

Formatted: Font: 12 pt, Superscript

Our study has demonstrated that early CPAP and a permissive ventilator strategy when compared with surfactant given within 1 hour of birth is associated with a significant reduction in death or survival with BPD as defined by the need for oxygen at 36 weeks from 54% to 48%. We also noted a very significant 8% reduction in death in our 24 to 25 week strata, resulting in a number needed to treat of 12.5 for each additional survivor. The group of 565 infants in our 24 to 25 week strata to our knowledge represents the largest prospective group of such immature infants to be randomized in any neonatal trial evaluating respiratory interventions. We believe

that this lower incidence of death in these infants along with a reduction of BPD and decreased durations of ventilation and exposure to post natal steroids in the overall CPAP group represents a substantial clinical benefit compared with the initial use of early surfactant.

Our rates of BPD are higher than those reported for the COIN trial, 33.9% vs 38.9%, but the difference between the arms is very similar. The higher rates seen in our study no doubt reflect the inclusion of infants of 24 weeks gestation and the lack of inclusion of infants greater than 27 6/7ths weeks, as well as the requirement in the COIN trial that the infants demonstrate adequate spontaneous breathing at 5 minutes of life.

We prospectively identified a number of safety outcomes that we chose to follow as investigators. These included the need for compressions in the delivery room, the occurrence of severe IVH, and the incidence of airleaks, initially defined as pneumothoraces but later altered to include pulmonary interstitial emphysema, pneumomediastinum and pneumopericardium. We did not find an increase in airleaks with the use of early CPAP at 5 cm H2O compared to the use of early surfactant.

The SUPPORT study was designed as a factorial design with each infant randomly receiving 2 interventions, CPAP vs Surfactant, and a lower versus higher SpO2 target range. While the study was not powered to detect an interaction between the 2 interventions, we did prospectively agree to evaluate such interactions and none were found. Both arms of the study were adequately powered for both the outcomes at neonatal discharge and the occurrence of survival NDI at 18 to 22 months and these results will be presented after all survivors have been assessed.

Conclusions:

ELBW infants between 24 and 27 6/7ths weeks gestation at birth treated with CPAP and a permissive ventilator strategy compared with the use of surfactant within 1 hour of birth and conventional mechanical ventilation have a decreased incidence of death or survival with BPD based on the need for oxygen at 36 weeks PCA with no demonstrable increase in any adverse neonatal outcomes. Early CPAP with a permissive ventilator strategy is associated with a significant reduction in mortality in the most immature infants. Surviving infants will have a complete neurodevelopmental evaluation at 18 to 22 months and these results will be separately reported.

Subject: NEOProm meta analysis of oximetry trials

Hi,

Lisa Askie, who is leading the prospective meta analysis of the oximetry trials for which we are participating from the SUPPORT Trial is asking for birth order and sibling match to be included in the final data set. We do have information on birth order and sibling match in our data, however, there is a question of whether we can share that information due to privacy issues. For example, if there is a set of quadruplets that might be a rare enough occurrence that sharing the information would make the infants identifiable. There is the additional complication that cases of multiple births in SUPPORT were randomized as a group (the pregnancy, not the infant, was the unit of randomization).

Please let me know if you are able to share this information on patients in the study of potentially triplets or even higher order multiples for the individual patient meta analysis. If you need to consult your IRB, please do so.

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

Please send me a response by October 23.

Thanks
Rose

Subject: RE: SUPPORT Ventilation and Oximetry papers | Author list and boilerplates
Date: Tuesday, October 06, 2009 5:18:58 PM
Attachments: SUPPORT enrollment by center 06OCT09.doc

Numbers on infants enrolled and eligible by center are attached. Note that I calculated the numbers in two ways. First, I looked at infants who met the SUPPORT inclusion criteria (inborn, 24-27 weeks GA, to receive full resuscitation, and no known major congenital malformations). Second, I looked at those who were "eligible" by subtracting those who met exclusion criteria (born during a time when personnel and/or equipment were unavailable) from those who met inclusion criteria. (In 119 out of the 125 cases where exclusion criteria were met it was because personnel were not available.) The numbers are similar for most centers, but there is a difference for a few, most notably Brown. I will leave it to others to decide which set of numbers are more reasonable to use for authorship order.

Sent: Tue Oct 06 14:04:20 2009
Subject: RE: SUPPORT Ventilation and Oximetry papers | Author list and boilerplates

Rose,

The numbers in the spreadsheet appear to come from the latest monthly report where the number eligible is calculated as described in the footnote:

Eligible GDB patients are those keyed in the NG02 (inborn and GA of 24 0/6 & 27 6/7) with a birth date after the first Support patient keyed for sites at each Center and not born on or between dates of Support study suspension 11/23/2005 and 2/5/2006.

As we have discussed before, these numbers do not match the numbers of infants on the SUPP02 which was supposed to be completed for "all inborn infants with a gestational age of 24 0/7 to 27 6/7 weeks gestation by best obstetrical estimates and who are to receive full resuscitation" and which captures additional eligibility information. I would be inclined to use the SUPP02 numbers, but what do you think?

Subject: NEOProm meta analysis of oximetry trials

Hi,
Lisa Askie, who is leading the prospective meta analysis of the oximetry trials for which we are participating from the SUPPORT Trial is asking for birth order and sibling match to be included in the final data set. We do have information on birth order and sibling match in our data; however, there is a question of whether we can share that information due to privacy issues. For example, if there is a set of quadruplets that might be a rare enough occurrence that sharing the information would make the infants identifiable. There is the additional complication that cases of multiple births in SUPPORT were randomized as a group (the pregnancy, not the infant, was the unit of randomization).

Please let me know if you are able to share this information on patients in the study of potentially triplets or even higher order multiples for the individual patient meta analysis. If you need to consult your IRB, please do so.

Please send me a response by October 23.

Thanks
Rose

I agree with Michelle. Even quads are not that unusual anymore. I don't see why we would view this information differently than other clinical information that's de-identified to the extent feasible (ie, we include birth date only when we need it).

Kris,
I can answer that question. Alamance is a separate legal entity from DUHS and would require its own IRB oversight. That can be accomplished in 1 of 2 ways: (i) by separate contract with their own IRB: or (ii) by contract with Duke to have the DUHS IRB act as their IRB-of-Record for this specific study. For option (ii), I have a template IRB Authorization Agreement to be signed by Duke and the site that establishes the DUHS IRB as the IRB for an external site on a study-by-study basis.

Thank you. Let me know if you need the template to forward to an external site.
Jody

Hi Mike,

Would the health system wide approval include Alamance if you decide to recruit there or do they have a totally separate IRB?
Thanks,
Kris

Subject: Fw: eIRB: Notification of Approved Amendment

HI Rose,

please see below the confirmation of IRB approval of the amendment to allow
us to access charts at DRH for the SUPPORT trial. I met with Jody Power this morning (cc'd on the email), she's the executive director the Duke IRB. She clarified for me that the Duke IRB is health system wide, meaning
that DRH is part of the 'covered entity' and is covered by the Duke IRB Federal Wide Assurance. We still needed DRH internal administrative approval before getting the IRB final approval, as they need to know that
some research is happening there.....(we got that today).....Jody will be
helping to address IRB issues/concerns on the site visit report reply.

thanks
mc

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

The Duke University Health System Institutional Review Board for Clinical Investigations (DUHS IRB) has conducted the following activity on the study cited above:

Activity: Amendment

Type of Review: Expedited

Protocol Expiration Date: 4/7/2010

Review Date: 9/30/2009

Pediatric Risk Category: 45CFR46.404 and 21 CFR 50.51 as applicable

Date of Declared Concordance with federally funded grant, if applicable:

DUHS IRB approval encompasses the following specific components of the study cited above:

Protocol version/date:

Consent form reference date: 10/06/2009

Investigator Brochure version/date:

Summary version/date: 09/29/2009

Amendment version/date:

Amendment ID: Amd2_Pro00015378

Federal Funding Agency ID: HD-00-010 Other

The DUHS IRB has determined the specific components above to be in compliance with all applicable Health Insurance Portability and Accountability Act ("HIPAA") regulations.
No change to the protocol, consent form or other approved document may be implemented without first obtaining IRB approval of the change. Any proposed change must be submitted as an amendment. If necessary in a life-threatening situation, where time does not permit your prior consultation with the IRB, you may act contrary to the protocol if the action is in the best interest of the subject. You must notify the IRB of your action within five working days of the event.

This study expires at 12 AM on the Expiration Date. At that time, all study activity must cease. If you wish to continue specific study activities directly related to subject safety, you must immediately contact Dr. John Falletta or Jody Power. Continuing review submissions (renewals) must be received by the DUHS IRB office 60 to 45 days prior to the expiration date.

The Duke University Health System Institutional Review Board for Clinical Investigations (DUHS IRB), FWA 00009025, is duly constituted, fulfilling all requirements for diversity, and has written procedures for initial and continuing review of human research protocols. The DUHS IRB complies with all U.S. regulatory requirements related to the protection of human research participants. Specifically, the DUHS IRB complies with 45CFR46, 21CFR50, 21CFR56, 21CFR312, 21CFR812, and 45CFR164.508-514. In addition, the DUHS IRB complies with the Guidelines of the International Conference on Harmonization to the extent required by the U. S. Food and Drug Administration.

Subject: RE: case question

HI Rose and Dale,

another query....we have an exam that found 'plus' disease a couple of weeks after discharge to home. The current NGO3 outcome page for patient 73171 ROP says 'no plus disease'...but the SUPP10 will include it, as it was diagnosed after discharge at an outpatient exam. (This eventually regressed.)...my question is that I am anticipating a query as gdb outcome will disagree w/ SUPP10 outcome....(plus disease in SUPP, no plus disease at status in GDB).....will this be a data consistency problem?

I agree with Dale - try to find the ROP exam where the child was fully vascularized based on DC summary. I checked the GDB manual - it appears that this is "Undetermined" based on the following of ROP in ZONE II:
3= Undetermined ROP status in either eye (and neither had 'severe ROP")
EITHER eye met one of the following criteria:
* Immature vessels in zone I or zone II
* Immature vessels reaching zone III for only 1 consecutive examination
* Stage 1 or 2 ROP in zone III for only 1 consecutive examination
* Stage 3 ROP in zone III
* ROP in zone I or zone II
* plus disease

Subject: RE: case question

Hi Mike,

I agree with your interpretation.

For SUPPORT, this infant's official primary outcome criteria are not met. There are not two sequential examinations improving in zone III. (not even one)
It is a missing primary outcome.

The adjudication process of such cases may be able to assign a "probably favorable outcome" to this infant as a secondary outcome, but I'm not confident of that. We will not be able to complete that before the abstract submission.

What puzzles me is why an ophthalmologist would not do a follow up examination on a very sick baby with zone II stage 2 ROP, even though now regressing. This was probably not a stable baby (he died in first year). His ROP had gone from stage 1 to stage 2 on the last two eye examinations, even though the last examination showed signs of regression. It was only one examination. Statistically, it is unlikely that he progressed to threshold after 43 weeks, but not unheard of.
:-(

One puzzle: why did the discharge summary say 'fully vascularized'? Was there another examination that you've missed in the medical record? One way to 'easily' skim for this would be in the medication record, if you have one electronically recorded. Look for orders for the dilating drops for an eye examination. It is a good sign of a probable examination.

Subject: case question

Hi Kris and Dale...my review of primary ROP outcome for case 72501 generates a question:

this baby's last exam was at 45 weeks post menstrual age. THe exam results clearly state zone 2 stage 2 OU,,,but also cleary written by the ophthalmologist as 'regressing.' Also,,,at the bottom of the note where the ophthalmologist write the recommended follow up, the opthalmologist

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

wrote
"1 year".....The previous exam, at 43 weeks PMA was zone 2 stage 1 OU. This was the baby's last exam prior to the baby's death at about one year of chronologic age, about 4 months before his first scheduled outpatient eye exam. The NICU discharge summary says "fully vascularized"....but I'd go with the ophthalmologist's exam note as primary source.

per the ngo3 in gdb definition for 'favorable' rop outcome at status, the def includes "rop in zone II or III, but determined to be clearly regressing" (which I think this baby meets)....For SUPPORT in the Manual of Ops,,,this isn't a defintion of 'favorable'....the SUPPORT MOP says "favorable" is an exam w/ full maturation at all clock hours or two sequential exams to zone III...

my take on this is that on GDB NGO3 we code "favorable", but the SUPP10 should list the baby as: Final outcome lost to follow up at 55 weeks "YES",,,,and Final ROP outcome determined at 18 month followup "NO"..because we lack an exam between 43 weeks post menstrual age and 55 weeks that had full vascularization or two sequential w/ vessels in zone III...

is this a correct interpretation?

Good afternoon Rosemary,

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

I am trying to resolve the latest "batch" of SUPPORT BPD queries that were sent to Wade Rich and I keep getting the following programming error message when I try to correct and complete the NG07:

MCH_IsMissingCode has been called on a value that is not a String Type (Field 2).

I have never encountered this error code and any advice would be greatly appreciate. Thanks for your attention to this matter in advance.

Best Regards,

Subject:	SUPPORT Neuroimaging Cohort Extended Follow-Up Subcommittee Update
Date:	Monday, October 05, 2009 12:00:10 AM
Attachments:	FINAL_SchoolAgeFollowUpSUPPORTNeuroimaging.pdf FINAL_Grid_SUPPORTSchoolAge_visit.pdf

Dear SUPPORT Neuroimaging Cohort Extended Follow-Up Subcommittee:

Thank you for your continued work and help on this long-term project! This email will serve as a brief quarterly update of our study.

SUPPORT Neuroimaging Cohort Extended Follow-up Protocol

o Subsequent to the recommendations of our subcommittee, final discussion of the SUPPORT Extended Follow-up protocol took place at the Neonatal Research Network Steering Committee meeting in June 2009.

o The steering committee approved the recommended changes, which included moving follow-up window forward by 6 months to 6 1/2 to 7 1/2 years, and the final changes to the test/questionnaire grid.

o The protocol is now final and is attached. The visit battery grid is also attached.

Tracking for school-age follow-up

o 18-22 month follow-up is ongoing, with greater than 90% follow-up rate so far.

o SUPPORT Extended Follow-up status form for documenting contact with patient families at 3-4 years **is required for each child**.

o Successful completion of this status form is required for release of capitation funds from NICHD to Network site - so this is a powerful incentive for successful tracking contacts.

Manual and forms development

o The most up-to-date versions of all tests and questionnaires to be used in the school-age follow-up visit have ordered (or are being ordered) by RTI, with the help of Jane Hammond and Jamie Newman. Manual and forms development is our next important step.

o The 6 1/2 to 7 1/2 year window for the first enrolled child will open in November 2011 - but only 10 children have windows opening before September 2012.

o Therefore, training will be targeted for late fall 2011 (catching the early patients later in their windows).

o **Our plan is to have manual and forms ready by late fall or early winter 2010 - giving Network sites about a year to provide final feedback and get through their IRB's before school age follow-up visits begin.**

Neuroimaging update

o Neuroimaging cohort size: 548 patients with "complete" neuroimaging (per MRI

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

Master FU spreadsheet). **This cohort is even larger than we had anticipated or hoped for. It will certainly be the largest extremely preterm cohort worldwide with comprehensive neonatal neuroimaging including MRI and planned school age follow-up.**

o Cranial US readings: Central readings by two central readers (Dorothy Bulas, Tom Slovis) are nearly complete - final CUS readings will likely be done by end October. Data are being entered as central reader forms are completed. **The plan is for preliminary analysis of CUS findings in time for PAS Late Breaker deadline (end February).**

o MRI readings: Whole Body Hypothermia for HIE trial MRI readings are now complete (and analysis in progress) - therefore, SUPPORT MRI central readings have been back on track and are currently ongoing. These readings are complex and time intensive. The goal was originally for completion of readings in time to allow preliminary analysis for PAS Late Breaker - but this may not be possible. However, preliminary analysis may be ready by the time of the PAS meeting itself, and could potentially be presented in part at the State of the Art Symposium on Neuroimaging in Preterm infants (organized by Mike O'Shea and Laura Ment).

Also, as you are aware, the SUPPORT main trial (Neil Finer, et. al.) enrollment was completed in February 2009. Analyses of primary short-term outcomes of this extremely important trial (including BPD and ROP) are underway.

Thank you again for your ongoing help and support. I will definitely be contacting you for further help and guidance as we embark on manual and forms development.
Susan

I) INTRODUCTION:

The **Surfactant Positive Airway Pressure and Pulse Oximetry Trial (SUPPORT)** is a prospective, randomized, factorial 2x2 design multi-center trial conducted by the NICHD Neonatal Research Network (enrollment completed February 2009). The trial will evaluate if CPAP and a permissive ventilation strategy and lower SpO_2 targets (85-89% vs. 91-95%) will result in increased survival without bronchopulmonary dysplasia (BPD) and increased survival without retinopathy of prematurity (ROP) among 24-27+6/7 week EGA infants. **The SUPPORT Neuroimaging and Neurodevelopmental Outcomes Study** is a prospective secondary study to SUPPORT of cranial ultrasound (CUS) at 4-14 days ("early CUS") and 35-42 weeks postmenstrual age (PMA) ("late CUS"), and brain MRI at 35-42 weeks PMA among infants enrolled in SUPPORT. The study was launched in May 2005, and 16 NICHD NRN sites participated. This study will allow us to assess the comparative and combined capabilities of early and late CUS and brain MRI to predict neuromotor and neurodevelopmental outcome at 18-22 months corrected age. The SUPPORT Neuroimaging and Neurodevelopmental Outcome cohort will be the largest such cohort assembled to date.

Children born extremely prematurely continue to have significant neurodevelopmental challenges in later childhood, yet many subtle but significant cognitive and performance problems cannot be delineated until school age. Early and accurate prediction of neurodevelopmental outcome would be invaluable, but CUS and other early variables do not reliably predict outcomes. White matter (WM) injury has been strongly implicated in neuromotor and cognitive impairment, and a link between WM injury and gray matter developmental disruption appears to exist. MRI is better than CUS in identifying subtle and diffuse WM injury, as well as cerebellar and gray matter abnormalities. Previous studies of preterm infants have shown WM injury by MRI to be significantly associated with CP and adverse *neurosensory* outcome, independent of CUS abnormalities. An independent association with *cognitive* impairment in early childhood has not yet been demonstrated. However, subtle neonatal MRI abnormalities may predict cognitive problems in early school age that cannot yet be delineated at 18-24 months. In addition, higher rates of behavioral and executive function impairments in childhood have been reported among very preterm infants, and previous studies have suggested that WM injury seen on neonatal MRI may predict these impairments. **We therefore propose to follow the SUPPORT Neuroimaging cohort at 6½ - 7½ years to test the primary hypothesis that neonatal brain MRI is superior to neonatal CUS in predicting death after discharge or cognitive impairment (Wechsler Intelligence Scale for Children-IV (WISC-IV) IQ<70) at school age.** We will also test whether neonatal brain MRI is superior to CUS in predicting neuromotor impairment, disability, and less severe cognitive impairment. We will also assess whether injury severity on neonatal MRI is associated with longitudinal cognitive and disability level changes, examine cognitive impairment and disability between ventilatory and oxygenation saturation SUPPORT intervention groups, and determine whether neonatal MRI is superior to CUS in predicting adverse executive and behavioral outcomes.

The SUPPORT Neuroimaging cohort is valuable and unique among other preterm cohorts worldwide. By pursuing 6½ - 7½ year follow-up, the NICHD NRN is in an outstanding position to substantially contribute to our understanding of later extremely preterm outcomes and their prediction.

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

II) HYPOTHESES:

Among children enrolled in the SUPPORT Neuroimaging and Neurodevelopmental Outcome Secondary with complete neuroimaging and surviving to hospital discharge:

PRIMARY:

- Neonatal brain MRI will be superior to neonatal CUS in predicting death after discharge or cognitive impairment (WISC-IV IQ<70) at 6½ - 7½ years.

SECONDARY:

- Neonatal brain MRI will be superior to neonatal CUS in predicting cognitive impairment (WISC-IV IQ<70) at 6½ - 7½ years.
- Neonatal brain MRI will be superior to neonatal CUS in predicting death after discharge or disability, or disability among survivors, at 6½ - 7½ years.
- There will be insufficient evidence to reject the null hypothesis that no differences exist in the risks of cognitive impairment, disability, or neuromotor impairment including CP between ventilatory or oxygenation saturation SUPPORT intervention groups in this sub-cohort.
- Neonatal brain MRI will be superior to neonatal CUS in predicting mild cognitive impairment (WISC-IV IQ 1-2 SD below population mean) at 6½ - 7½ years.
- Neonatal brain MRI will be superior to neonatal CUS in predicting CP and neuromotor/movement impairment at 6½ - 7½ years.
- Moderate to severe white matter injury on neonatal neuroimaging will be associated with behavior and executive function impairments at 6½ - 7½ years.
    - Neonatal brain MRI will be superior to neonatal CUS in predicting behavioral and executive function impairments at 6½ - 7½ years.
- Severe developmental impairment and severe cerebral palsy at 18-22 months will be highly predictive of severe disability at school age, but mild or moderate impairment at 18-22 months will be poorly predictive of later outcome group.
- Injury severity and pattern on neonatal MRI will be associated with longitudinal cognitive and disability level changes (18-22 months corrected age → 6½ - 7½ years).
- Brain injury pattern and topography on neonatal MRI will be associated with anatomic and functional type of CP at school age.
- High rates of health-related quality of life challenges and chronic or disabling conditions will be observed.
    - These findings will be associated with moderate-severe brain injury on neonatal neuroimaging.
- Local readings of neonatal MRI will be less predictive of 6½ - 7½ year outcomes than central reading.

Specific Aims:

- To assess cognitive, neuromotor, functional and behavioral outcomes of the SUPPORT Neuroimaging cohort at 6½ - 7½ years of age
- To examine the independent associations of neonatal neuroimaging findings with neurodevelopmental outcomes
    - Assess the absolute and relative value of early and late neonatal CUS and neonatal MRI, alone and in combination with other risk factors, to predict normal and impaired outcomes

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

- To examine longitudinal changes in cognitive and overall impairment level from 18-22 month to 6½ - 7½ year exams, and assess relationship of neonatal neuroimaging abnormalities and other variables.
- To compare 6½ - 7½ year neurodevelopmental outcomes of ventilation and oxygenation SUPPORT randomized groups in this sub-cohort.

II) BACKGROUND AND SIGNIFICANCE:

Long-term neurodevelopmental outcomes of extremely preterm infants:

Despite advances in perinatal and neonatal management and improvement in survival, short-term neurodevelopmental outcomes of extremely preterm and extremely low birth weight (ELBW) infants remain guarded (Vohr, Hintz #1, Hintz #2, Costeloe). This high frequency of disability in very early childhood (18-24 months) makes longer-term neurodevelopmental outcome studies crucial. Evaluation at a later age allows identification and delineation of a broader range of problems, including cognitive delay, more subtle motor, movement, and coordination disabilities, and behavioral and executive function problems to be determined. It also allows for assessment of the strength of perinatal and neonatal variables as potential predictors of long-term outcomes, and for longitudinal analysis to determine the predictive value of early disability.

Later childhood follow-up studies have demonstrated that significant neurodevelopmental and cognitive impairment continue for extremely preterm infants. In the 206 ELBW infants followed at 5 years in the Finnish National Cohort (Mikkola), 20% had major disabilities, and 19% of those <27 weeks were diagnosed with cerebral palsy (CP). The EPICure Study Group (Marlow) reported on 241 <26 week survivors at 6 years; severe overall cognitive delay was present in 21% compared with test norms (41% compared with term controls), and disabling CP was diagnosed in 13%. In a study of 219 ELBW infants at 8 years (Hack #1), Hack, et. al. reported CP in 14%, severe cognitive impairment in 15%, moderate-severe cognitive impairment in 38%, and significant motor skills problems in 27%. Families reported substantial functional limitations, including emotional delay, trouble understanding or communicating, and need for medication or equipment. Needs for special services were significantly greater than for the normal birth weight (NBW) control group. Impairment in academic (32%) and adaptive skills (48%) have also been reported among ELBW children, and are significantly more frequent than in NBW controls (Taylor). In an ELBW or <28 week EGA cohort at 8 years (n=275), Anderson, et. al. reported significant impairment across all tested cognitive and educational abilities compared with NBW controls (Anderson #1). Although improvements in neurosensory impairment rates have reported over time with successive ELBW birth cohorts in VICS since the 1970's, neurologic disabilities continue to be substantially more common among ELBW children at school age than their normal birth weight peers (Doyle #1).

Summary: Children born extremely preterm or ELBW continue to have significant motor and cognitive disabilities in childhood, as well as more subtle functional and adaptive impairments. Delineation of some of these problems may not even be reasonably undertaken until 5-8 years of age. The true impact of these impairments may not be felt until later school age (Saigal).

Neonatal CUS and other variables to predict neurodevelopmental outcomes

CUS and short-term outcomes (18-24 months)

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

The association of severe neonatal CUS abnormalities and adverse short-term neurodevelopmental outcome has been reported in numerous studies (Vohr, Hack #2). But the strength of this association appears to be consistent primarily for combined developmental and neuromotor endpoints, or for CP or motor disability alone, but not for pure cognitive delay (deVries, Hack #2, Wood). In addition, severe CUS abnormalities are not uniformly predictive of adverse short-term outcome and normal CUS do not predict normal outcome in this high-risk population (deVries, Hack#2, Laptook, Ancel, Pinto-Martin). In fact, in a predictive modeling analysis, Ambalavanan found that severe grade of IVH explained only 8% of the variance in low MDI and 5% of the variance for major handicap at 18-22 months (Ambalavanan).

CUS and long-term outcome (5-8 years)

Reported associations of neonatal CUS findings and long-term outcomes are inconsistent. Sherlock, et. al. (Sherlock) reported that neurodevelopmental impairment at 8 years varied little with increasing severity of IVH; a trend for worse cognitive and neurosensory outcome with higher grade IVH in that study was explained solely by the outcomes of the small number of patients with parenchymal hemorrhage. The Neonatal Brain Hemorrhage Study (NBHS) showed that 88% of LBW patients with germinal matrix or IVH had normal cognitive outcomes (Whitaker) at 6 years.

Nevertheless, several analyses have reported abnormal neonatal CUS to be "significantly associated with" adverse long-term neurodevelopmental outcomes in ELBW cohorts. For instance, Mikkola found an association of abnormal CUS with CP and IQ at 5 years (Mikkola), and Taylor found an association of abnormal CUS with executive function and memory on the NEPSY (Taylor). However, the definition of CUS "abnormality" varies among studies, with some analyses including markers of white matter injury (PVL or ventricular enlargement (VE)) and others limiting only to IVH. In addition, a finding of association does not specifically address the independent *predictive* power of neonatal CUS, particularly with respect to cognitive outcome in later childhood. In fact, Hack, et. al. demonstrated that only 36% of those with a Mental Processing Composite (MPC) of <85 at 8 years had had an abnormal CUS, and only 45% of those with MPC<70 (Hack #3). In the 6-year follow-up of the NBHS cohort, only 12% of those with GM/IVH had borderline IQ or mental retardation (Whitaker). In that study, PVL/VE was separately assessed; this revealed a stronger 56.5% of those with PVL/VE had borderline IQ or mental retardation. This may be a clinical insight to the importance of white matter (WM) injury for longer-term adverse outcomes *including cognitive outcomes*. Nevertheless, more that 40% of patients with PVL/VE had normal intelligence at 6 years - a finding, which, in turn, may serve to underscore the inability of routine CUS to see anything more subtle than the most definitive WM injury.

Other potential predictors of long-term neurodevelopmental outcome:

Investigators have attempted to determine other, more reliable predictors of longer-term outcomes of preterm infants. Doyle reported on prediction of survival free of major disability at 5 years among the surviving VICS cohort on the basis of the *number of adverse neonatal variables* experienced by the child (Doyle #2). Although observed and predicted values were similar, the outcome was not specifically focused (i.e., combined neurologic/neurosensory/cognitive endpoint), the observed 95% CI range was broad for 2 and 3 variable groups, and the patient numbers were quite small. Others have assessed the predictive value of *earlier neurodevelopmental findings*. Marlow found that only severe

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

disability at 30 months was highly predictive of 6-year outcome; 38% of children defined as mild or moderately disabled and 24% with "no disabilities" had moderate or severe disabilities at 6 years. Hack (#3) found the positive predictive value of MDI<70 at 20 months for MPC<70 at 8 years to be extremely poor (PPV=0.37). However, some intriguing links between neonatal brain injury and longitudinal decline in cognitive ability have been reported. In follow-up to the I-IVHP trial, Ment found that cognitive scores declined from 36 to 96 months only in the subset of patients with early IVH coupled with PVL or VE (Ment). Also from the I-IVHP trial, the presence of spastic cerebral palsy at 3 years was more strongly predictive of IQ<70 at 8 years than was cognitive testing at 3 years (Pleacher). These findings are interesting, but perhaps not surprising, in light of the proposed mechanism linking white matter injury with reduced connectivity, gray matter loss, and cognitive delay (Boardman, Inder).

Summary: Aggregate abnormal findings on neonatal CUS do not reliably predict either short- or long-term neurodevelopmental outcomes, although markers of WM injury appear to be stronger links. Early cognitive measures also do not predict later cognitive outcome well in most circumstances. These findings emphasize the deficits of routine CUS to detect subtle injury, and also underscore the poor predictive validity of early cognitive measures for later cognitive outcomes (Aylward). These findings also suggest that better delineation of neonatal WM injury may enhance efforts to predict outcomes.

MRI: Delineation of injury and predicting outcomes

Imaging brain injury:

MRI provides a more complete and anatomically detailed evaluation of the neonatal brain. Studies comparing the relative capabilities of US with MRI to detect brain injury among preterm infants in the newborn period have shown that MRI detects white matter injury better than CUS (Maaloof, Childs), and provides additional information on brain development not noted by cranial US. Studies have also demonstrated that subtle and diffuse WM injury, not detectable by CUS, may be common among preterm infants at term (Counsell).

White matter injury and cognitive outcome:

Cognitive delay is a significant impairment and difficult to predict. Recent studies have demonstrated that WM injury in the preterm infant is associated with both reduced cortical gray matter volume, and with reduced deep gray matter volume by MRI at term equivalent age (Inder, Boardman). There are several potential mechanistic pathways, including via direct axonal or subplate neuron injury that may explain this finding. The common endpoint is reduced connectivity, limited neuronal differentiation, and poor cognitive outcome. In fact, recent research using MRI tractography in a series of former preterm infants at approximately 2 years of age has provided at least proof of concept for this theory of reduced cortical and thalamic connections after WM injury (#2 Counsell).

Brain and WM injury by MRI and executive and behavioral outcomes in preterm infants:

Extremely low birth weight and very preterm infants have been reported to be at greater risk for executive dysfunction, as well as emotional and behavioral problems at 2 years, 4 years and at school age (#2 Anderson, Woodward #1, Taylor). These problems are infrequently the focus of neurodevelopmental outcomes studies, and are considered by some to be less serious than cognitive impairment. However, impairments across these domains have substantial impact on academic achievement, follow-up needs, and family

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

interactions. Recent studies have suggested that these impairments may be associated with specific brain injury types and patterns among preterm children. In a brain diffusion tensor imaging (DTI) MRI study of preterm and term adolescents, Skranes, et. al. (Skranes) demonstrated that the preterm group were more likely to have attention deficit hyperactivity disorder (ADHD) and autism spectrum disorder (ASD) diagnoses or symptoms. Those with ADHD and ASD had lower fractional anisotropy (FA) in many WM areas, consistent with WM injury and impaired WM connectivity throughout the brain. Recent analyses have also demonstrated that WM injury on near-term MRI may predict executive and behavioral problems among preterm infant in early childhood. In a single center study, abnormal near-term MRI in VLBW infants was associated with positive M-CHAT screen in early childhood (Limperopoulos). Impaired working memory performance (Woodward #2) and self-regulation (Clark) at 2 years have both been associated with moderate-severe WM injury on near-term MRI. Specific regional injury patterns have furthermore been associated with working memory deficits.

MRI in preterm infants and early neurodevelopmental outcome

After early studies suggesting that MRI at near term was a more powerful predictive tool than CUS for short-term neurodevelopmental outcome (Valkama, Roelents-van-Rijn, Mirmiran), larger MRI studies were undertaken. Many have been single-center efforts, focused chiefly on the association of early neurodevelopmental outcomes with MRI findings in preterm infants at term and earlier, and without extensive comparison of the predictive validity of MRI and CUS. Among these, Miller, et. al. (UCSF, <34 weeks EGA, 86 survivors) and Dyet, et. al. (Hammersmith, <30 weeks EGA, 119 survivors) described MRI findings from birth through near-term and found that WM injury, particularly diffuse injury, was common and was associated with adverse neurodevelopmental outcomes. Recent evidence has also suggested that WM injury on neonatal MRI predicted motor developmental delays at 1 year corrected age with high specificity among very preterm infants (Spittle). Cerebellar injury, not easily seen with routine CUS, was also a prognostic indicator of poor outcome. Of importance, although MRI data were meticulously obtained, only 66% of the group had complete follow-up information.

However, other groups have preterm MRI cohorts, with research aims that include comparison of predictive capabilities of MRI and CUS.

- The 2-year neurodevelopmental outcomes of the New Zealand (NZ) cohort (Woodward #3) (<30 weeks EGA, 167 survivors) revealed that 1) presence of moderate-severe WM abnormalities on MRI was significantly associated severe motor delay and cerebral palsy, independent of CUS abnormalities and other risk factors; 2) a significant correlation between white and gray matter abnormalities; 3) although increasing severity of WM injury was associated with worse Bayley MDI scores, an independent association of moderate-severe WM injury with severe cognitive delay was not reached. Although sensitivity of moderate-severe WM to predict CP (65%), neurosensory impairment (82%) and severe cognitive delay (41%) was improved over abnormalities on CUS (18%, 16%, and 15%, respectively), the total number of the cohort with moderate (n=29) or severe (n=6) WM injury was small, and approximately half of those did not have neurodevelopmental impairment.
- The 2-year results of the Australian cohort (<1250 g or <30 weeks EGA, n=221) (Hunt) showed "major" white matter injury to be a more significant independent risk factor than PVL for CP. Major WM injury was found to be an independent risk factor for

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

neurosensory disability where PVL was not. IVH grade 4 was not found to be a significant risk factor for either outcome.

- **SUPPORT Neuroimaging and Neurodevelopmental Outcomes cohort:** The birth date of the first enrolled patient was 5/10/05. Enrollment was completed with SUPPORT main trial in February 2009, and follow-up at 18-22 months is ongoing.

SUPPORT Neuroimaging cohort: Unique and valuable

The SUPPORT Neuroimaging cohort, comprised of ~530 extremely preterm infants surviving to near-term with complete CUS and MRI neuroimaging will be the largest preterm brain MRI cohort worldwide with comprehensive early childhood follow-up. This cohort is also a higher-risk group than other cohorts, and thus targets one of the most important outcomes groups. The SUPPORT Neuroimaging cohort is inherently exceptional due to its development within a randomized controlled trial. Thus, the management profile of a crucial neonatal care component has been more carefully controlled and monitored than would otherwise be the case. This also allows for secondary analyses of the association of respiratory management strategies with subtle MRI findings and with outcomes. The SUPPORT Neuroimaging cohort also has a number of advantages over other preterm/MRI cohorts:

1) New Zealand (NZ) cohort:
    a. Setting: SUPPORT: Embedded in a randomized controlled trial within a multicenter network with focused neurodevelopmental follow-up priorities; NZ: two centers one in New Zealand another in Melbourne, Australia, with a primary focus on MRI imaging
    b. EGA/risk profile:
        i. SUPPORT: <28 weeks EGA; NZ cohort: <30 weeks. In the NZ cohort, only 87/167 were <1000 g BW, and 95/167 were <28 weeks.
    c. Cohort size: SUPPORT: ~530 survivors to near-term; NZ: 167 survivors at 2 years.
    d. Timing/interpretation of CUS:
        i. SUPPORT: Two CUS required by the study protocol at specific times (4-14 days and near-term); NZ: number and timing of CUS not required as part of study protocol, but reported CUS usually obtained within 2 days, 5-7 days, 4-6 weeks; if "abnormality" detected, more frequently performed.
        ii. SUPPORT: central reader, detailed data collection; NZ: No central reader. "Worst" CUS findings recorded only related respect to PVL/echolucency, grade 3 or 4 IVH
    e. Timing/interpretation of MRI:
        i. BOTH: Near-term
        ii. BOTH: Central reader
        iii. SUPPORT: detailed MRI central reader data collection form; NZ: central reader data collection instrument not known, but MRI abnormality categories broad.
    f. Non-imaging data collection:
        i. SUPPORT: extensive, including detailed respiratory data; NZ: less detailed
2) Australia cohort:
    a. Setting: Single center in Melbourne, Australia

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

b. EGA/risk profile:
    i. <30 weeks, <1250 g.
c. Cohort size: 221 survivors at 2 years.
d. Timing/interpretation of CUS:
    i. Not required, retrospectively gathered data (communication, Rod Hunt).
    ii. "Worst" CUS findings gathered - PVL, grade 4 IVH
e. Timing/interpretation of MRI:
    i. Near-term
    ii. Central reader
f. Non-imaging data collection:
    i. Routine

3) Hammersmith cohort:
    a. Setting: Single center
    b. EGA/risk profile:
        i. <30 weeks.
    c. Cohort size: 119 survivors at 2 years. **Note: complete follow-up data were available for only 66% of the group**
    d. Timing/interpretation of CUS:
        i. CUS not focus – studies thus far report MRI
    e. Timing/interpretation of MRI:
        i. MRI serial – from birth to near-term
        ii. Central reader
    f. Non-imaging data collection:
        i. Routine
4) UCSF:
    a. Small, single center
    b. <34 weeks
    c. 86 survivors at 2 years
    d. CUS not focus – MRI's serial from birth to near-term
    e. Non-imaging data routine

Summary: MRI is better than CUS in identifying subtle and diffuse white matter injury, which is relatively common among preterm infants at term, as well as cerebellar, and gray matter abnormalities. Early small and single-center studies suggested that MRI better predicts adverse neuromotor outcome than CUS. Two-year results of the NZ cohort have shown WM injury by MRI to be significantly associated with CP and adverse neurosensory outcome independent of CUS abnormalities, but not with adverse cognitive outcome. The extent to which these findings will be enhanced and clarified, and how or when MRI should be applied in routine clinical practice, awaits the 18-22 month follow-up results of the larger, higher-risk SUPPORT Neuroimaging cohort. However, a biologic mechanism exists for the link between WM injury and cognitive impairment. Early neurodevelopmental findings are poor predictors of later challenges, but subtle neonatal WM abnormalities by MRI may predict cognitive, behavioral, and executive function impairments at school-age that cannot be delineated at 18-22 months.

Later outcomes: Need for SUPPORT Neuroimaging extended follow-up

Evidence for altered brain development: Corroboration of need for long-term follow-up

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

Short-term neurodevelopmental outcomes are only a tiny window into the future of a former preterm child. Difficulties in cognition, performance, verbal/language skills, attention and behavior may not be delineated until later ages. There are also data to support the concept that even minor, undiagnosed brain injury sustained preterm infant is associated with disordered brain development. Rademaker, et. al. found that even minor differences in lesion severity on MRI performed at 8 years of age in <32 week EGA appeared more accurate in prediction of IQ and total impairment score than neonatal CUS (Rademaker). These findings may suggest that subtle injury could have been seen on *neonatal* MRI, which in turn, could have aided in prediction. In a DTI and volumetric MRI study, Yung demonstrated that *neurologically normal* LBW preterm infants at 8-12 years had significantly reduced WM volumes than term controls, and that this was significantly related to reduced IQ (Yung). This finding again suggests that early WM injury leading to reduced volume may have been identifiable on neonatal MRI. Kesler, et. al. described high-resolution MRI results from 73 preterm and 33 term infants at 7-11 years of age; preterm infants had disorganized cortical development, potentially involving disrupted neural migration (Kesler).

Importance of SUPPORT Neuroimaging secondary long-term follow-up

- Our current ability to predict later childhood outcomes from perinatal and neonatal variables is limited. The prognostic validity of neonatal CUS findings is limited, particularly for cognitive outcomes. Even early childhood neurodevelopmental outcome, apart from severe impairment, do not accurately predict later childhood neurocognitive outcome. MRI holds promise as a better predictive modality, but neonatal MRI has not been evaluated on a large scale with respect to long-term, school-age outcomes.
- Performance skills are different at 18-22 months than 6½ - 7½ years. Assessments at the later age may uncover subtle, yet significant problems, including attention/behavior problems, language and verbal delays, and academic impairment, which may be predicted by neonatal WM brain injury seen by MRI.
- The SUPPORT Neuroimaging and Neurodevelopmental Outcomes secondary was designed with MRI/CUS predictive comparison in mind.
- 18-22 month follow-up is already part of this secondary study. Thus, there is a crucial and rare opportunity to evaluate longitudinal neurodevelopmental changes, and importantly, how neonatal brain injury patterns and other variables may be associated with changes in cognitive or functional outcomes over time.
- This is a prospectively enrolled secondary cohort, embedded within SUPPORT RCT. These patients have therefore had a more consistent respiratory management approach, and comprehensive respiratory data collection. This provides a unique opportunity for analyses of randomized ventilation/oxygenation arms of Neuroimaging cohort outcomes at 6½ - 7½ years.
- Neurodevelopmental follow-up is already a focused objective of the NICHD NRN, and extended 6-7 year follow-up has recently been undertaken for a previous trial (Shankaran). In developing this SUPPORT Neuroimaging school-age follow-up protocol, we have been able to utilize experience gained from the challenges faced during the previous extended follow-up project.
- Other preterm/MRI cohorts, notably the NZ cohort, already have moved forward with longer-term follow-up (Clark, Woodward #1).

III) STUDY DESIGN:

Objective: This is a prospective, extended follow-up study of 6½ - 7½ year neurodevelopmental outcomes of the SUPPORT Neuroimaging Secondary cohort. We will evaluate and compare the capabilities of *neonatal neuroimaging* - CUS and near-term MRI – to predict cognitive impairment, disability, and neuromotor impairment at 6½ - 7½ years. We will evaluate longitudinal changes in neurodevelopmental outcome, and assess associated neuroimaging findings and other variables. We will also determine if ventilatory or oxygenation saturation SUPPORT interventions are associated with differences in 6½ - 7½ year neurodevelopmental outcomes.

Outcomes:

- Primary:
  - IQ by WISC-IV<70 or death after discharge
- Secondary:
  - IQ score (continuous) by WISC-IV among survivors
  - Disability
    - Severe: Any of: WISC-IV>3 SD below mean, severely impaired neuromotor/functional outcome (non-ambulatory, GMFCS level 4-5), profound hearing loss or blindness (not functionally correctable),
    - Moderate: Any of: WISC-IV2-3 SD below mean, moderately impaired neuromotor/functional outcome
    - Mild: Any of: WISC-IV1-2 SD below mean, mildly impaired neuromotor/functional outcome (abnormal neurologic exam, but walking independently, GMFCS level 1-2)
  - Neuromotor, movement
    - Cerebral palsy, classified anatomically and functionally according to Definition and Classification of Cerebral Palsy, February 2007 guidelines (Baxter) ; Motor and coordination impairment, as determined by administration of the Movement Assessment Battery for Children, version 2 (M-ABC-2) (Burns, Smits-Engelsman).
  - Mild-moderate cognitive impairment (WISC-IV 1-2 SD below mean), severe cognitive impairment (WISC-IV 2-3 SD below mean), and profound cognitive impairment (WISC-IV>3 SD below mean)
  - Executive function and achievement delays (evaluated by NEPSY-II subtests; Behavior Rating Inventory of Executive Function (BRIEF, parent form) (Roze); Woodcock-Johnson III subtests (Taylor))
  - Behavioral and attention deficits (evaluated by Strengths and Difficulties Questionnaire (SDQ) (Goodman, Muris); Conners' Rating Scale (ADHD short form only); Social Communication Questionnaire (SCQ) (Chandler, Eaves))
  - Chronic conditions and health-related quality of life concerns (evaluated by the Questionnaire for Identifying Children with Chronic Conditions – revised (QUICCC-R) (Stein); the Pediatric Quality of Life Inventory (Peds QL) (Majnemer))

Study population:

- The study population (SUPPORT Neuroimaging cohort) will be comprised of the SUPPORT Neuroimaging and Neurodevelopmental Outcome Secondary enrollees

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

who survived to discharge, with complete neuroimaging. **It is estimated that approximately 530 patients meet these criteria.**

- As described in the SUPPORT Neuroimaging and Neurodevelopmental outcome secondary, these patients will have had two CUS (early: 4-14 days of age; late: 35-42 weeks and within 5 days of MRI) and a brain MRI at 35-42 weeks.
    - The CUS with the most severe abnormalities (the "worst" CUS) will be used in comparative analyses
- Estimated cohort size at the time of neurodevelopmental follow-up
    - Follow-up at 18-22 months (ongoing)
        - Estimate 3% death after discharge, 10% loss to F-U:
            - **Cohort=~460 patients**
    - Follow-up at 6½ - 7½ years
        - Estimate additional 20% loss to follow-up:
            - **Cohort = 370 patients**

Design:

- This study is a long-term cognitive, neuromotor, functional, executive function, behavioral assessment of the SUPPORT Neuroimaging cohort at school age (6 ½ - 7 ½ years). **No further neuroimaging is being proposed**.
- Visit at 6½ - 7½ years:
    - The visit battery was assembled and revised after extensive discussions with Protocol Review Subcommittee, Extended SUPPORT Neuroimaging and Neurodevelopmental Outcomes Subcommittee, external advisory reviewers, NRN Follow-up PI group, NRN site psychologists, and evaluation of the challenges and successes of the Extended Hypothermia Follow-up study. The following issues were particularly addressed:
        - Length of visit: Tests and questionnaires were chosen to balance the need for robust neurodevelopmental evaluation, but remain within the confines of a reasonable academic study visit period.
        - Age at visit: Due to differences in age at school start across the U.S., as well as the fact that the WISC-IV "floor" is at 6 years 0 months, there was strong concern that a 6-7 year window would be suboptimal. Therefore, the follow-up window for this study is 6 ½ - 7 ½ years, which will hopefully ameliorate the potential for insufficient sensitivity of WISC-IV for low functioning children at very young ages, and allow for more consistent school exposure across the cohort.
        - Language for tests and questionnaires: There was consensus that tests and questionnaires should be available and normed in Spanish, particularly the instrument used for the cognitive evaluation (primary outcome). It is noted that the NEPSY-II is not available in Spanish. However, site "credit" for a visit will not be linked to attempt of the NEPSY-II in the case of Spanish-speaking children. Furthermore, the BRIEF (parent questionnaire) is available in Spanish, providing some input on the child's executive function.
    - Following is the test and questionnaire grid; note that the child testing and parent questionnaires can be administered simultaneously. Furthermore, the "Break" as presented is a suggested timing. It is understood that each child is an individual, and the NRN site psychologist will determine timing and number of breaks throughout the visit for that particular child's needs.

Statistical considerations:

Analyses:

- Since we are concerned with the relative diagnostic power of the MRI versus the CUS, an appropriate statistical methodology is an ROC analysis. This analysis is based on the sensitivity and specificity and compares the diagnostic power over the entire range of the diagnostic variable(s) and thus negates the need to select "cut points". The analysis related to the primary hypothesis will compare the ROC curves for a predictive model based on the MRI data versus a predictive model based on the CUS data. The WISC-IV < 70 or death after discharge will be the primary outcome variable. The WISC-IV < 70 among survivors will also be evaluated as an outcome variable.
    - We will conduct the ROC analysis with WISC-IV <70 (or death after discharge) as the outcome when either MRI or CUS data are in the predictive model and will compare the ROCs for the two models for statistical significance. Since MRI and CUS are done on the same subjects, it will not be necessary to adjust for risk factors in comparing the two tools.
        - In separate analyses, NRN center may be entered as a variable to assess the confounding effects of site. Although CUS and MRI are

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

centrally-read, and significant attempts to ensure reliability and consistency of WPPSI evaluation across sites will be made, unanticipated and unmeasurable differences between sites in quality of neuroimaging or in WISC-IV administration *may* confound analyses;

- We will conduct the ROC analysis with WISC-IV <70 (or death after discharge) as the outcome when only "traditional variables" (non-neuroimaging variables) are the only variables in the model;
- We will also do the ROC analysis that compares the contribution of MRI and CUS to the prediction of outcome above and beyond that of the traditional clinical variables.
- Will also do the ROC analysis that compares the incremental value of adding MRI to the prediction of outcome above and beyond that of traditional clinical variables plus CUS
- Logistic regression analysis will be used to compare 6½ - 7½ year neurodevelopmental outcomes (or death after discharge) between oxygenation and ventilation SUPPORT randomized groups. These analyses will be adjusted for baseline risk variables.
  - The baseline risk variables pre-specified for adjustment in the main SUPPORT trial are the stratification variables (NRN site and GA group). In comparing 6½ - 7½ year outcomes between SUPPORT randomized groups, we plan to adjust only for these variables in our initial approach. However, since the Neuroimaging cohort may not be representative of the originally randomized study cohort, we will investigate differences between the 6½ - 7½ year follow-up groups and consider a subsequent level analysis adding other factors if there is an indication of systematic differences.
- Local vs. central neuroimaging secondary analyses: As recommended by the Protocol Review Subcommittee, secondary analyses including evaluation of local MRI reading will be undertaken.
  - Local CUS readings are already collected in the SUPPORT or GDB database; local MRI readings (print-out of final local read with study ID and center written on the document, but patient identifiers removed or blacked out) will be collected.
  - Accuracy of local compared with central neuroimaging interpretation will be performed by sensitivity and specificity analyses (Hintz #3).
  - Additional analyses will compare capability of local MRI read and central MRI read to predict 6½ - 7½ year outcomes by ROC analysis.

- "Traditional non-neuroimaging variables": Based on previous investigations assessing the associations of demographic, socioeconomic, perinatal, and neonatal factors with school-age outcomes (Taylor, Doyle #2), we propose the following non-neuroimaging variables will be used in model development; other variables may be considered.
  - Center
  - Gestational age
  - Race
  - Gender
  - Multiple gestation
  - Maternal education level (at baseline)

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

- [SUPPORT treatment group]
- Sepsis or meningitis
- NEC
- BPD
- Postnatal steroids
- ROP stage III or more severe
- Length of initial hospital stay (EGA adjusted, i.e., PCA at discharge)
- Any surgery during initial hospitalization

Sample size and power analysis (Primary Hypothesis):

- The sample sizes in the table below are based on formulae for two correlated ROCs (e.g. two ROCs based on the same sample). According to the discussion in the protocol above, we assume that around 370 infants will be available for the 6½ - 7½ year IQ evaluation, assuming ~20% loss to follow-up between 18-22 months and school-age. For a two-tailed test at the 0.05 level of significance and assuming the lowest area under the ROC curve (AUC) for the MRI and the CUS is 75%, an even more conservative estimate of 350 children would produce the powers in the table below for an array of detectable increases in the AUC and prevalence of outcome.

POWER FOR SELECTED INCREASES FROM 75% IN THE AUC OF THE ROC AND PREVALENCES OF THE PRIMARY OUTCOME:
SAMPLE SIZE = 350

AUC Inc. / Outcome P	5%	6%	7%	8%	9%	10%
20%	31%	43%	55%	67%	77%	86%
25%	37%	50%	64%	76%	85%	92%
30%	42%	56%	70%	81%	90%	95%

Hence, if the prevalence of the primary outcome is as low as 20% a conservative sample size of 350 would identify an AUC increase of 10% with reasonable power (86%); if the prevalence is 30%, the detectable increase would be 8% (with power 80%).

Budget: The costs of this proposed follow-up study would span over several years. The first enrolled patient will reach the 6th birthday on 05/10/2011, thus the first window will open 11/10/2011. **It is estimated that 6½ - 7½ year follow-up windows will extend from November 2011 to late 2016.** A range of costs for some subcategories has been provided for loss to follow-up rates between 18-22 months to 6 ½ - 7 ½ years of 10% - 20%.

- Tracking: Similar to the Extended Follow-up of the Hypothermia Trial, tracking will be critical to ensure the best possible follow-up. **Tracking tools and forms have already been developed and launched. RTI is sending tracking reminders to sites.** Because of the importance robust school-age follow-up rates, considerable

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

funds have been budgeted for tracking contacts. The following are suggested contact schedules, although each site will implement specific tracking and contacts appropriate for their patients:
  - Between 18-22 month and 3-4 years: <u>at least</u> 2 phone or other family contacts/ tracking events
  - Between 3-4 years and 6½ - 7½ years: <u>at least</u> 4 phone or other family contacts/ tracking events
  - **$420 per child has been budgeted for tracking.** Release of tracking funds will be contingent on completion of the SEF01 form (tracking form for 18-22 month to 3-4 year contacts).
  - **Total**: **$155,400 – $174,300**
- <u>Consents</u>: Consent to contact families for possible 6½ - 7½ year follow-up is currently being sought at the 18-22 month visit. Tracking will then commence as noted above. Formal signed consent will be obtained for the majority of the cohort at the time of the 6½ - 7½ year follow-up visit. It is expected that the consent process will take ~1/2 hour (@$35/hour).
  - 14 patients had already been seen in 18-22 month follow-up prior to Dr. Higgins' announcement to NRN site PI's and Follow-up PI's to request to maintain contact. These patients will require some additional time for tracking/consent. We expect that the consent process will take ~1 hour in these cases (@$35/hour).
  - **Total: $6475-$7263**
- <u>Local MRI read:</u> We estimate that relatively little time (~1/2 hour per MRI x $35/hour) will be required to print out/copy final local MRI report, black out patient identifiers, and write in Center number and subject number. These documents will then be sent to RTI.
  - **Total: $9275**
- <u>Training and assuring reliability:</u> The first enrolled SUPPORT Neuroimaging cohort patient will reach the extended follow-up window opening in November 2011. However, there are just 10 patients in the first "wave" with the majority of patient windows not opening until February 2012. Furthermore, given the length of the SUPPORT trial, the final enrolled patients will have 6½ - 7½ year follow-up windows that extend to late 2016. Thus, the total cohort follow-up period will span approximately 5 years. To ensure ongoing training and achieve the best possible reliability for the primary outcome measure (WISC-IV), the following training and reliability assessments have been determined:
  - Training sessions: We propose adding another WISC-IV training session for all sites midway through the follow-up (late 2013 or early 2014). As with the Extended Hypothermia Follow-up, these training sessions will also include training in other components of the follow-up exam, including the NEPSY-II and PEDI. 15 sites are participating in the SUPPORT Neuroimaging secondary, but the 15th site (Emory) will not have patients reaching the 6th birthday until after 2013. We have also added incrementally to the cost per site in 2013 to adjust for inflation.
    - First training session (Fall 2011): $3200 x 14 sites =$44,800
    - Second training session (late 2013): $3400 x 15 sites =$51,000
  - Reliability assessment: In response to Protocol Review Subcommittee comments, we propose ongoing routine exam taping to be sent from

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

participating sites to one of two GOLD STANDARD WISC-IV psychologists. After training and subsequent certification by one taped exam on a non-study patient, the first 3 exams from each site be taped and sent for review and comment, then approximately every 10th exam. This approach will necessitate a DVD recorder to be purchased by each site. We estimate that 3 hours will be required to review and comment upon each WISC-IV exam at $60/hour. Gold standard psychologists will assure that turn-around for comments on these exams be rapid so that sites can incorporate feedback in subsequent scheduled patients' visits. Thus, the budget would reflect the following:

- DVD recorders for each site: $350 x 15 sites = $5250
- Review and comment on certification exam =
  - 1 x 15 sites x 3 hours x $60/hr = $2700
- Review 1st 3 exams from each site =
  - 3x15 site x 3 hrs x $60/hr = $8100
- Review of every 10th exam: Dependent on follow-up numbers:
  - Approximately 30 additional exams x 3 hrs x $60/hr = $5400

- **Total = $117,250**

- 6½ - 7½ year visit costs:
  - $1200 per child has been budgeted for the study visit
  - **Total = $444,000-$498,000**

TOTAL BUDGET ESTIMATE: $732,400 - $806,088 *plus RTI costs*

From: Stevens, Timothy
To: Higgins, Rosemary (NIH/NICHD) [E]
Subject: RE: Pulmonary outcomes at 6-7 years
Date: Monday, October 05, 2009 11:30:10 AM

Hi Rose,

Yes, I am writing it. I just received comments back from Richard and will get it to you soon. Is there a timeline that I should follow?

Bill asked whether this is the sort of study that could be submitted as an RO1 to offset network costs and provide investigator support for me. Is that a viable option (depending on its fundability of course).

Thanks

Tim

To: 'Richard Ehrenkranz'; Stevens, Timothy
Subject: Pulmonary outcomes at 6-7 years

Hi,
Were you still planning on submitting a proposal to the Network for pulmonary outcomes (concept approved) for SUPPORT at school age?

let me know

Thanks
Rose

From: Phelps, Dale
To: Higgins, Rosemary (NIH/NICHD) [E]
Subject: RE: SUPPORT Ophthalmology
Date: Monday, October 05, 2009 10:59:01 AM

Hi Rose,
Oct. 20 would be fine. Let me know what time, (not before 10:30am Eastern time please)

I will send a message to Dr. Wallace about the adjudication and communication to come from you or RTI. Actually, who should I say?

I would like to remain involved in how this is set up and done. It that possible? I did have quite the experience with this when EMMES Corp. set it up for the STOP-ROP study.

Dale

Subject: SUPPORT Ophthalmology

Dale
Can we set up a call for ophthalmology exam adjudication for the SUPPORT study (October 20 would be good if you are available). Also – Can we correspond directly with Dr. Wallace at Duke?
Thanks
Rose

Hi,
Didn't know how separate you needed the tables so in the zip file they are separated by site and protocol and the adobe files have all protocols by center.
Thanks,
Kris

NICHD NRN Duke Site Visit
September 29, 2009

NICHD: Dr. Rosemay Higgins
Data Coordinating Center: Kristin Zaterka-Baxter, Carolyn Huitema
Duke University: Drs. Ronald Goldberg, Michael Cotten, Kimberly Fisher

Minutes

Regulatory Review

New to the review process at Duke is the Site Base Research Unit (SBRU) related to billing and budget. The intent is to insure that a billing grid is developed and used for billing tracking with respect to research and clinical costs covered by insurance. Standard of care medical items and procedures must also be included in this billing grid. The billing grid with color coding for a protocol must be done before the protocol can be submitted for departmental and IRB review. The Duke NRN group will have to go back and develop a billing grid for each active study as the IRB yearly approvals come up. The SBRU does not charge for their review but the amount of time unit or research staff spends preparing for this review is substantial. Time includes finding CPT codes and working with the PRMO (pricing oversight office).

Once the SBRU approves the protocol then the NRN staff at Duke may submit the protocol through the following series of review:

1) Departmental Review (Dr. Cotten serves on this board). This can take a turnaround time of 1-4 weeks
2) Department Chair to assign pediatric risk level. Turnaround time is 1-3 days.
3) IRB medical writer reviews application with a turnaround of 1-2 weeks. They mainly look at the wording of the consent form.
4) Then, the protocol moves to IRB review.

Currently there are 8 IRBs at Duke, 4 chairs and 8 vice chairs. If assigned a low risk, the protocol is usually expedited. If higher risk, the protocol goes to Full Board. A primary reviewer is assigned and usually approves the protocol with minor changes. The water mark consent does not get released by Office of Research Assistants (ORA) until the SBRU grid is approved after any final additional changes. This appears to be a burdensome process. The Duke NRN site IRB approvals take longer than many to most NRN site IRB approvals.

Dr. Fisher usually takes care of the IRB and SBRU process and can call on others to help as needed.

Renewal announcements are sent 2-3 months before the deadline however, the Duke NRN staff tracks the renewals. They can only submit a renewal 60-45 days from deadline.

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

Duke has a current indirect rate of 57%. This may require renegotiation to compensate for the extensive reviews. A new Vice Dean of Clinical Research has just been appointed.

Dr. Fisher suggested that UNC-CH submit at the same time to prevent a gap in the approvals. UNC-CH usually receives IRB approval prior to Duke. The UNC site cannot recruit until the Duke primary NRN site has IRB approval as the data is entered through the NRN computer at Duke.
Current status of upcoming trials:

- INS2 has gone through departmental review. Now that the doses are assigned, it is moving to Full Board review
- NEST is in the SBRU process

Other Study Sites

Durham Regional Hospital (DRH)
The Duke NRN staff has access to the discharge summaries at DRH from which GDB data are collected. For the SUPPORT Trail, the Duke site decided not to recruit at DRH due to the issue of keeping track of the Masimo study oximeters. It was decided by the Duke staff to try not to transfer children in the SUPPORT Trial on study oximeters to DRH since it would be very difficult to manage them on the study and rarely do they transfer children on oxygen to DRH. and they tended to hold onto infants who were enrolled in SUPPORT. Infants born at DRH were not enrolled in SUPPORT though mothers at risk for extreme preterm deliveries were usually transferred to Duke. but they did try to move mothers who might delivery eligible infants. The Duke NRN staff were unsure if they had permission to collect SUPPORT data elements from DRH. The Duke NRN staff were unsure if they needed DRH IRB approval or if DRH is part of the Duke University Healthcare System and therefore one approval from the Duke IRB is needed. Dr. Cotton learned that DRH does accept Duke IRB approval but that DRH must administratively approve the study. DRH no longer has a separate IRB. Dr. Cotton submitted and amendment to the Duke Support Trial submission to include DRH. Since DRH is listed in the Duke NRN grant application as a population available for clinical trials, NICHD requests that the Duke site insure that they can collect research data from DRH.

Comment [k1]: This sounds like they are keeping kids in house longer than medically necessary because they are enrolled in a research study; would delete this text

Comment [k2]: This too; sounds like they are transferring kids to Duke just because of the study; not because all high risk pregnancies get transferred to Duke; would also delete

There was confusion regarding the determination of status for Support study patient transferred to DRH due to the uncertainty of IRB approval status at that site., Seven study infants who were transferred to DRH were coded with a status of transferred in the Support trial data and coded as discharged to home in the GDB data (because these infants were discharged to home from DRH). Additionally, if the infant was transferred prior to 36 weeks PMA to DRH, the Support Trial data collection was halted at time of transfer. Ultimately, it was determined that Duke would gain the regulatory and administrative approval from Duke and DHR respectively in order to collect and amend the necessary research data.

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

Alamance Regional Medical Center:
Alamance has a low census and separate IRB. They currently do not participate in the NRN studies. The census may increase since they are working with public health clinics. If this is the case; Duke will recruit infants to study with local IRB approval. If the census does not improve, a modification of the Duke NRN grant application listing Alamance Regional as part of the population base for research studies may be requested.

Comment [k3]: Rose; not sure this is correct about the grant app)

Duke Health-Raleigh:
This site has closed since the grant application was filed.

Moore Regional Hospital:
Clarification is requested regarding whether Moore Regional is a participating Duke site for the recruitment and enrollment of NRN study infants.

University of North Carolina at Chapel Hill (UNC-CH)
This site was added in November 2008. Since, they have obtained IRB approval to conduct GDB data collection and 2 NRN research studies. Enrollment and data collection seem to be going well (Duke has been asked to send all UNC IRB approvals and approved informed consents where applicable to RTI fro their records). Since UNC staffs their research office separately from it was suggested that Duke, as the primary site, plan to monitor data collected by UNC with source documents as a matter of QA/QC.

Study Consent
A consent/data entry issue was discussed regarding a case where parent(s) gave consent for SUPPORT but declined GDB. The parent(s) were re-approached for GDB consent during their infants 18M follow up visit. Consent was granted at that time however the Support data was held until GDB approval was granted. This resulted in a SUPPORT enrollment post completion of study recruitment.

Guidelines should be put place for research studies requiring GDB data a part of the interventional study to insure all research data are obtainable and in an appropriate timeframe. This is a site issue and the site needs to insure that patients enrolled in trials will have the necessary research data available for collection.

Embedding the GBD consent to collect data into the clinical research trial consent was proposed as a possible solution. Drs. Cotton and Goldberg will investigate this possibility however have indicated that in the past, their IRB was very much against the approach of 'bundling' studies into one consent. The possibility of complete de-identification of GDB study data was discussed as a possible avenue for requesting waiver of consent for GDB, however, Duke regulatory guidelines indicated that any link to a study subjects identification, including study logs kept in house, render that subject as identifiable and thus requires the potential subject's consent to participate (parental consent).

Performance
Dr. Higgins presented the most recent NRN snapshot of performance (June 2009) at all NRN centers. This sheet will be distributed to the study section for peer review when the

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

network is reviewed in fall 2010. Duke was falling behind at 68% ROP outcome for SUPPORT at end of June.

To resolve this issue Duke recently developed a plan to obtain a copy of all in-house and out-patient return visit ROP exam reports and maintain a copy of these reports in the research files. Until recently there was significant difficulty in obtaining a copy of the ophthalmology report from the Duke Eye Center. When this was ultimately brought to Dr. Goldberg's attention in the last month or so, a phone call from Dr. Goldberg improved this process. When the study infants are discharged, Duke NRN staff calls the outside ophthalmologist to get a copy of the exam (with an acceptable form of authorization, i.e., signed medical release form or copy on the study informed consent)

There were11 patients in the NRN DMS as of 9/25/09 that did not have final outcome for ROP. This was corrected on site at the time of this review.

Meetings

There are two weekly meetings. The first meeting is a larger pediatric research meeting with all research staff including the Duke NRN staff and other investigators. The second meeting includes NRN research nurses and data entry and is headed by Dr. Fisher.

Going forward, NICHD requests that a weekly meeting be held with Drs. Cotton, Goldberg, Fisher, NRN research nurses and staff, follow up and data entry staff. This will facilitate communication and hopefully prevent delays in issues being addressed such as delays with the eye exams that were previously encountered at the site. Duke has taken steps in planning for these meetings.

Protocol Communication

The protocol is received by NRN (passed concept stage and initial protocol review). The process initial review process begins at Duke with protocol review by PI, Alt PI and FU PI as well as select faculty for specific expertise/interest for input. The study PI compiles responses from faculty and hopefully identifies a study champion among faculty with interest/expertise. After, the protocol is more generally presented to faculty, fellow, NNPs. NRN staff also begins IRB preparation with consideration of protocol development timeline within the NRN. Once Network approved, the NRN staff work on the regulatory documents for Departmental review. NRN staff responds to Department recommendations and once approved at this level, ultimately submit for IRB/IRB chair review. Once final IRB approval has been granted, NRN staff plan in-service(s) for the NICU clinical team.

Staffing/Hiring

The Human Resources (HR) department at Duke seems to be an obstacle in hiring appropriate staff in a timely manner. There is a need for several staff (research nurses/study coordinators) in the NICU research department and there are several positions posted which are seemingly difficult, at best, to fill. The salary for these positions is set by the Duke HR department, regardless of the available NIH grant funding for NICHD projects. The salary listed on the grant is not the salary used in the

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

Duke system to advertise the job. A lower salary is used, perhaps limiting the applicant pool and generating less qualified applicants. It is not clear to NICHD how guidelines are used to set the salaries if a key personnel position at a requested salary level has been listed in the grant application. Once the candidate is identified, the process for a job offer takes approximately 1 month. Dr. Goldberg stated that qualified candidates were lost because they took other positions which were offered in a timelier manner. Given the essential and critical role of the research coordinator at the NRN sites, efficient recruitment for this position is necessary. The current coordinator, Gloria Siaw, began work in mid-March 2009, the previous coordinator resigned with an effective date of December 31 leaving the research coordinator position vacant for over 2 months.

Enrollment

NRN research coordinators and nurses as well as neonatal fellows and faculty participate in enrollment of infants to study. Dr. Cotten, Goldberg, Goldstein and Fisher primarily discuss the NRN studies with patent(s) of potential infants and seek written consent. Dr. Cotten is primarily responsible for SUPPORT and the 6-24 Hour Hypothermia consent process and Dr. Goldstein facilitates the Preemie aEEG consenting process. Dr. Goldberg assists where necessary.

In addition to the NRN studies, there are about 42 active trials (industry and grant funded). The only foreseeable conflict for enrollment is with an on-going anti-fungal medication study (Fluconozole) with the upcoming Inositol Multi-dose Pk study and they are both conducted under IND.

Data Collection

NRN Staff may need to approach parent(s) for consent several times if necessary prior to consent being granted. Dr Goldberg or Cotton may also approach parent(s) for further discussion of study participation. Follow Up consent is now typically obtained just before discharge. GDB data is collected in real time on Monday, Wednesday and Fridays primarily by the research coordinator and research nurse with assistance of the clinical research director where necessary. For interventional studies, data is collected daily. There are recent operating procedures in place that allow source documentation to be readily available in the patient research record.

Forms are completed and sent to the Data Entry person (presently Charles Vajdl) for keying data into the NRN DMS computer located at his desk. If he has data questions, he flags the forms and asks the Research Coordinator (presently Gloria Siaw), the Research Nurse (presently Stephanie Crosby) or the Director of Clinical Research (presently Dr. Kim Fischer) for assistance. The later three staff also assist in data entry when required. All NRN staff have been trained and certified to enter data in the NRN DMS to ensure cross coverage.

Currently there are no formal quality checks on UNC-CH data. Duke and UNC research staff meet on a monthly and this would provide good forum to review data and research processes. Regulatory information is kept in a single location at UNC-CH. All IRB

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

approvals and approved consent forms must be sent to RTI for both Duke as well as UNC.

Procedure for Queries, Edits and Data Quality

The data entry person prints off edits and works with the research coordinator and director to resolve them. Duke had the highest rate of missing forms for the Support trial (just under 50% of the total forms outstanding cross NRN centers) as of September 3, 2009. A written plan for procedures and process for dealing with and resolving queries and edits is required from Duke.

Dr. Higgins sends missing primary outcome data to all sites on a monthly (or more frequent interval depending on the state of a trial) basis to all NRN sites. Drs. Goldberg, Cotton, Fischer, and Ms. Siaw receive the list. If there are follow up outcomes, Dr. Goldstein is also notified. Dr. Goldberg forwards to Drs. Cotten and Fisher and Ms. Siaw. It is not clear who has the responsibility for resolving the queries and edits; staff need to be identified and responsibilities outlined in detail for resolution of missing forms, batched edits and queried. Dr. Fisher is now in the process of resolving outstanding in light of several staffing issues.

Cross checks with GDB and SUPPORT have been generated by RTI. It is of great concern that 5 infants in SUPPORT had grade III or IV IVH reported on SUPP09, but no IVH on the NG03 status form. Both forms are using the same definitions for IVH. The data need to be consistent on individual infants and the site is requested to insure consistency and accurate data collection. A plan for cross checking data should be put into place at the site.

Action items requiring a response to NICHD by October 15, 2009:

1. The collection of research data at DRH needs to be addressed and resolved so that source document can be obtained on infants in observational studies and trials can have complete data in the DMS.
2. A written plan for the process and resolution of edits and queries needs to be formulated and instituted at the Duke site detailing responsibility for staff completing the entry to RTI. This must be sent to NICHD.
    a. All SUPPORT missing forms, batch edits, queries and action items listed below must be resolved immediately.
3. Duke is required to have all SUPPORT study primary outcomes for all 64 cases verified and the Primary Outcomes Report signed by Dr. Goldberg and/or Dr. Cotton to ensure the integrity of the data.
    a. In addition, it is imperative that all data and neuro-images be sent to RTI immediately for the Support Neurodevelopmental Secondary Study. There are currently 2 infants with missing MRI images (72101; 72051)
4. A Weekly meeting for the NRN research staff (PI, alternate PI, Follow Up PI, clinical research director, research coordinator, research staff and data entry staff) is strongly encouraged to facilitate communication, resolution of current

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

outstanding data, and ongoing protocol updates as well as other items relevant to NRN research.

5. The establishment of a communication plan for the Rochester site conducting the SUPPORT Secondary Breathing Outcomes interviews is requested. Ms. Zaterka-Baxter will Assist Dr. Fisher and send the necessary information to establish this process. THE Breathing Outcomes FU windows for all patients are posted to the private NRN gateway.

Recommendations

1. The inclusion of frequent transfer sites (NHMH; Rex Hospital) in NRN study informed consented to allow collection of required study data was suggested but it is understood that is the prevue of the Duke IRB.
2. The Duke site appears to have an arduous IRB process as well as challenges with hiring and retaining coordinators for the NRN activities. It is suggested that the PI work with the appropriate individuals at the institution to facilitate these two areas that have been a bit challenging for the NRN at Duke.

Full Case Review

(b) (6)

Support Trial Outcome Data:

ROP outcome data reviewed against source documents (ophthalmologic reports);

Action Items:

None

BPD outcome data reviewed against source documents (medical records)

Action Items:

None

Follow up #1271

Action Items:

1. Follow Up Consent was not available in the study folder; please copy and submit to RTI. Noted was a signed North Carolina Infant Toddler Authorization to disclose health information.
2. No CRFs were included in the study folder though NF09A was verified using remote data; please update study files

(b) (6)

Support Trial Outcome Data

ROP outcome data reviewed against source documents (ophthalmologic reports);

Action Items:

1. Amend and verify data for exam date (b) (6); per source documentation, it does not appear the infant had threshold disease in the left eye.
2. Per chart review on 09/01/09; please verify and enter exams for the following data in the DMS:
   (b) (6)

BPD outcome data reviewed against source documents (medical records)

Action Items:

1. Post Duke IRB approval to collect pulmonary data at DRH; please enter all data to 36 weeks /status on the NG07 and Supp11

Follow up #1278

Action Items:

1. Not all CRFs were included in the study folder (NF01 and NF09A were reviewed); please update study files

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

(b) (6)
Support Trial Outcome Data

ROP outcome data reviewed against source documents (ophthalmologic reports);
Action Items:
1. Final ROP status missing; resolve or amend data

BPD outcome data reviewed against source documents (medical records)
Action Items:
1. Data inconsistent with source documentation in the supp11 for date (b) (6) @ 0600 time point – should be CPAP (4) not CV (2). Please amend data

Follow up # 1342
Action Items:
1. Follow Up Consent was not available in the study folder; please copy and submit to RTI
2. No CRFs were included in the study folder though NF09A was verified using remote data; please update study files

(b) (6)
Support Trial Outcome Data
ROP outcome data reviewed against source documents (ophthalmologic reports);
Action Items:
1. Source documentation is inconsistent with data entered in DMS; dates of exams appear to be inconsistent with reported findings ((b) (6) {fully vascularized}); please review and amend data. Please copy all eye exam reports and send to RTI once data are amended for further review.

BPD outcome data reviewed against source documents (medical records)
Action Items:
1. No action items but noted that infant transferred to REX at 33 wks PCA (b) (6) on RA at 36wks.

Follow up # 1438
Action Items:
1. None; follow up window not yet open

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

(b) (6)

Support Trial Outcome Data

ROP outcome data reviewed against source documents (ophthalmologic reports);

Action Items:

1. Source documentation is inconsistent with data entered in DMS;
2. No SUPP09 in DMS; please key and transmit data
3. SUPP10-missing eye exams
    a. Missing exam in DMS on (b) (6) source documents indicate infant had Left eye-surgery on this date; please amend data
    b. No source document for ROP exam on (b) (6); DMS indicated data for right eye-surgery on this date; please verify
    c. Source documents indicate infant has plus disease; documented on GDB NG03 Q.H.1.a.1 and NO; please verify and amend data. Please send missing eye exam reports to RTI for further review

BPD outcome data reviewed against source documents (medical records)

Action Items:

None

Follow up # (none assigned at this time); Follow up window not open

Action Items:

1. Please verify if infant was consented at discharge; if so, provide a copy of the informed consent to RTI

(b) (6)

Support Trial Outcome Data

ROP outcome data reviewed against source documents (ophthalmologic reports);

Action Items:

1. Source documentation is inconsistent with data entered in DMS; the last to ROP exam reports are not entered in the DSM; please update system and send reports to RTI for further review.

BPD outcome data reviewed against source documents (medical records)

Action Items:

1. Infant transferred to DRH prior to 36 weeks; please amend correct all missing data on Supp11 and NG07 with local IRB approval and submit data to RTI.

Follow Up #1471

Action Item:

1. Follow Up Consent was not available in the study folder; please copy and submit to RTI
2. No CRFs were included in the study folder though NF09A was verified using remote data; please update study files

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

(b) (6)
Physician removed infant from study due to unblinding of the oximetry arm; the infant was not withdrawn as documented in the data. The Supp06 PD from will be amended and all data with be entered in DMS with approved consent from parents.

Support Trial Outcome Data

ROP outcome data reviewed against source documents (ophthalmologic reports);
Action Items:

1. Source documentation inconsistent with entered data; final ROP outcomes of laser surgery in both eyes documented per source on (b) (6) but reported in DMS as occurring on (b) (6); please amend data

BPD outcome data reviewed against source documents (medical records)
Action Items:

1. In light of resolution of infants status (not withdrawn), please update all data and transmit to RTI. SUPP11 need to complete forms

Follow up # (none assigned at this time); Follow up window not open
Action Item:

2. Please verify if infant was consented at discharge; if so, provide a copy of the informed consent to RTI

BPD Phys Def vs. BPD 02 Cases

(b) (6)
Findings and Action items:

1. NG07 v 1.1.06 question 8, 36 wk snapshot = YES (NC). SUPP11 is coded as NC all day at 36 wks but PHY01 is coded as nasal CPAP YES and did not answer NC question. Question 8 circled as YES at 36 wk snapshot (form in file, yes to vent, CPAP or NC and RA). Please verify data and verify whether infant was eligible for the physiologic challenge for BPD.
2. Question B.4 on the PHY01 is coded as YES for vent or CPAP; if data are correct above on the NG07, amend data in Q.B.4 and B.7 and transmit to RTI.

(b)
Findings and Action items:

1. Refer to above case. Fixed in DMS on-site

(b)
Findings and Action items:

1. Noted that the 36 week date on the Supp11 was incorrect; this is noted for the sites use, this data is not keyed. No action required.

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

(b) (6)
Findings and Action items:
1. Verfiy oxygen use at transfer. SUPP11 (coded as using oxygen) on day of transfer which does not match NG07 at Status (RA at status).

(b) (6)
Findings and Action items:
NG07 36 wk BPD data verified vent or CPAP and RA. No action required

(b) (6)
Findings and Action items:
Refer to above.

Transferred Cases

NG07 data were deleted because Duke changed status from discharged to home (form DRH) to transfer (from Duke). It was unclear whether DRH was a participating ancillary site of Duke and under appropriate IRB review. Duke will clarify whether DRH fall under the Duke University Health System regulatory prevue. With IRB approval, Duke will amend the NG03, NG07, Supp09, Supp10 and Supp11 data (where applicable) for the infants listed below.

Additional Findings upon brief review requiring attention:

(b) (6) No threshold disease per source documents but coded in the DMS as such; please verify
(b) (6) NC v. CPAP at36wk; please verify
(b) (6) 11/3/09 oxygen=4, updated and fixed in DMS on 9/27/09
(b) (6) No additional comments
(b) (6) RA vs oxygen at 36 weeks; please verify data
(b) (6) Transferred at 33 weeks to Rex Hospital on oxygen however 36 week data per NG07 is coded as on RA; please verify data and amend.
(b) (6) Incomplete Supp10 data; right eye exam on (b) (6) is not entered in the DMS
(b) (6) No additional comments

Other Items

New Queries generated 9/29/2009 and should be completed immediately

Rose
I have completed the queries listed in the the text as follows

(b) (6) - I spoke to Kris about this and we had it keyed incorrectly so it has been corrected and transmitted tonight
(b) (6) are both subjects that were transferred to (b) (6) but the 36 week info has now been re-keyed and has been transmitted

The attachment titled "Infants Missing ROP Outcomes at Center 19" with 5 infants listed has been completed and transmitted. I spoke with Kris aobut this and had to make one other correction which has been done.

I will work on the BPD attachment tomorrow.

Thanks for all your help!

Rose and I were talking earlier and thought that we should also send out the ROP queries (about data inconsistencies) we had discussed at the Rockville meeting and a few others Rose has suggested (for example, comparing surgery on the NG03 and SUPP10). I will get those together ASAP to send to the centers.

Subject: SUPPORT missing data updates

Attached are the following:

1) A zipped file containing documents for each center with unresolved BPD queries. (Centers without a document have no outstanding queries.) Queries that have potential to change the BPD outcomes are highlighted in yellow. Other queries address missing forms (like the SUPP11) and other data inconsistencies that will not necessarily affect whether the infant is classified as having BPD or not.
2) A zipped file containing documents for each center with infants who are missing final ROP status. (Centers without a document have no outstanding ROP outcomes.) Note that these documents list all infants without a ROP final outcome, including those whom the centers have coded on the SUPP10 as having the acute ROP outcome missing at 55 weeks PMA and/or having not obtained final ROP status at the 18 month FU visit.
3) An Excel file with the usual missing data reminders for ROP, BPD and FU.

We are currently missing ROP on 104 infants: 4 have been withdrawn from the study, 1 with vessels in zone 1 at last exam, 47 with vessels in zone 2 at last exam, and 52 with vessels in zone 3 at last exam. However, the 104 also includes three infants who were found at follow-up to have died after discharge, two at about 7 months old, and one at about a year old. Thus, we are missing ROP outcomes for a total of 97 infants who have not died and who have not been withdrawn from the study.

Subject: RE: SUPPORT missing data updates
Date: Friday, October 02, 2009 2:57:34 PM

Hi Rose, I know we just spoke on the phone, but here is the response I was writing. There was one other question I meant to ask you, which was whether you are alright with Neil's response that we will use the strict definition of supplemental oxygen for the "traditional" BPD outcome (leaving kids on room air by vent or CPAP to be classified as BPD=No)?

RESPONSE TO EMAIL BELOW:
Right now all infants but one currently have a classification for the BPD/death outcome. The one with a missing BPD outcome is one of the Duke infants who had some data deleted that will hopefully be restored soon. However, there are 7 cases where resolution of the BPD queries could change the BPD classification for the physiologic definition, and 18 cases where query resolution could change the outcome for BPD by the supplemental O2 definition. Those are the queries that I have highlighted in the documents I just sent you.

How many final BPD outcomes are unresolved?

From: Gantz, Marie [mailto:mgantz@rti.org]
Sent: Friday, October 02, 2009 2:34 PM
To: Higgins, Rosemary (NIH/NICHD) [E]
Cc: Finer, Neil; Wally Carlo; Rich, Wade; Das, Abhik; Zaterka-Baxter, Kristin
Subject: SUPPORT missing data updates

Attached are the following:

1) A zipped file containing documents for each center with unresolved BPD queries. (Centers without a document have no outstanding queries.) Queries that have potential to change the BPD outcomes are highlighted in yellow. Other queries address missing forms (like the SUPP11) and other data inconsistencies that will not necessarily affect whether the infant is classified as having BPD or not.
2) A zipped file containing documents for each center with infants who are missing final ROP status. (Centers without a document have no outstanding ROP outcomes.) Note that these documents list all infants without a ROP final outcome, including those whom the centers have coded on the SUPP10 as having the acute ROP outcome missing at 55 weeks PMA and/or having not obtained final ROP status at the 18 month FU visit.
3) An Excel file with the usual missing data reminders for ROP, BPD and FU.

We are currently missing ROP on 104 infants: 4 have been withdrawn from the study, 1 with vessels in

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

zone 1 at last exam, 47 with vessels in zone 2 at last exam, and 52 with vessels in zone 3 at last exam. However, the 104 also includes three infants who were found at follow-up to have died after discharge, two at about 7 months old, and one at about a year old. Thus, we are missing ROP outcomes for a total of 97 infants who have not died and who have not been withdrawn from the study.

Hi Rose
I would suggest that for the CPAP-Surf paper the authors be Finer, Carlo followed by the order you suggest and that for the SpO2 paper the authors be Carlo, Finer and the order that you suggest. I would like Wade and Marie in the first 5 or 6 authors for each paper.
Well in fact the truth be told, I would prefer NO AUTHORS - but I won't go there!!

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

Wade has played a key role in these trials. He and I essentially designed the offset oximeters, and he has also has been involved in looking at all the data and has been an effective author, reviewing all the results and each and every revision in detail.

The Boiler plate etc should be the same for both papers
Neil

Neil and Wally
We need to develop the authorship order for SUPPORT. The subcommittee members are listed following you as the first author for each paper. Generally, the more involved folks on the subcommittee are ordered to the front of the list. After the subcommittee, the sites are listed (usually in recruitment order). The statistician(s) can be listed where ever you feel the effort dictates. Let me know if the two of you would like to discuss (we probably should have discussed this on Monday on our call), or we can do it by email. Stephanie can generate a title page with order and author affiliations.

Thanks

On 10/1/09 1:53 PM, "Wally Carlo" <wcarlo@peds.uab.edu> wrote:

Dear Rose, Neil, Abhik, and Marie:

Enclosed is the draft 5.0 of the O2 saturation paper. Thank you very much for getting your comments to me. I have heard from everyone in the group. I have made changes, essentially accepting every suggestion.

There are several remaining issues at this stage.

1. The saturation cut off of the monitors. I have stated that at less than 85% and higher than 95% displayed values return to actual values as this happens at 84% saturation and at 96% saturation. Thus, I thought it would be easier to state less than 85% and higher than 95% as these numbers are used clinically. We may want to instead use the symbols < or >. One person suggested to use less than or equal to 84% and greater than or equal to 96%. I am concerned that these numbers may be

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

different to what most clinicians use in practice. I have reviewed the information we have from Massimo and the values less than 85% or higher than 95% may be the easier way for our readers to understand what we did.

2. There is a statement about safety outcomes monitored by DSMC. I am not sure what outcomes were monitored besides mortality, pneumothorax, and IVH. If there are others I can add them. Abhik: Were there other major outcomes monitored by the DSMB?
3. Figure 2 still needs the final numbers. I have not changed the figure. I have also not changed the tables or the numbers in the text, pending the final updated data.

Obviously once we get more data, some of the wording (particularly the results and discussion) will change. However, I think we should try to have as near a final manuscript as soon as possible, pending final data.

Thanks

Subject: BPD edits and other issues

Thanks for the manuscript, Neil.

I have checked all the BPD queries we sent in July, and there are still 74 infants with issues that need to be cleared up. The good news is that most centers have 5 or fewer. I count a total of 8 queries that could impact the infant's classification of BPD by the physiologic definition and 17 that could impact the outcome of BPD by supplemental O2 use. In addition, there are 27 cases where we are missing SUPP11 forms and BPD is currently being set based on NG07 data. This is important because I have been checking the NG07 against the SUPP11 for consistency and in these 27 cases I have not been able to do those checks. Thus, once the SUPP11s are entered we could find that there are additional inconsistencies that need to be cleared up. Note that some of the 74 queries mentioned above are actually new queries that arose because additional SUPP11s were entered as a result of the previous round of queries and they were found to conflict with the NG07 data.

Do you want RTI to send out the new BPD queries/reminders or do you want

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

Rose to send them again? I can highlight the queries that I know might change the BPD outcome so that the centers can address them with high priority.

As you all know, Michele Walsh and I were on a call this week regarding code being developed at RTI for the consensus definition of BPD. A couple of issues arose during the call that also impact the BPD outcomes for SUPPORT. One was the issue of how babies on RA by vent or CPAP should be classified (for the traditional BPD outcome) which Rose also brought up this week (there are 18 such cases in the SUPPORT data). Michele suggested that if we had an adjudication committee these babies could be part of the group that the committee would review. Another group of concern was those who qualified for the room air challenge but were not challenged due to 'instability' (N=2) or for 'other' reasons (N=25). Some of those 'other' reasons were things like 'personnel not available' but some were more informative. Long ago I had sent Neil a spreadsheet listing those 'other' reasons, but if there is an adjudication committee perhaps those infants should be included in the group that are reviewed. Another group that the committee might look at is those who were on vent for surgery - I have identified 3 such cases from the PHY01 reasons challenge not done and F5s on the NG07.

Finally, the other thing I need to look at are the cross-form queries to address inconsistencies such as IVH reported on one form but not another. We have received responses from 11 of the centers for these queries that were sent out in early September. I will look at these responses and outstanding queries and let you know what the status is.

Wade, I will try to re-run your analyses next week.

Marie
Weekly reports would be terrific.

Can you generate a list of ALL missing ROP final outcomes for one more chance at the sites (in case they can find a late exam). Please indicate if the site has reported these infants as "lost" on the ROP outcome.

I think we need to generate the report weekly for the next three weeks in hopes of getting the stragglers. (If not too much to ask)

Thanks
Rose

To: Higgins, Rosemary (NIH/NICHD) [E]
Subject: RE: SUPPORT!

Rose,

As of this weeks' data we are missing final ROP status on 96 infants who have not died or been withdrawn from the study, and 38 of them have been coded by the centers on the SUPP10 as having the acute outcome lost to FU at 55 weeks and/or having not obtained the final ROP status at the 18 month FU visit. Thus, ROP missing data reminders are not generated for those 38 infants when I run the report every 2 weeks. For the request below, I have looked at Case's data and they only have the one lost to FU infant without a ROP outcome (which is terrific, and I will send them an email to confirm that's the only missing case). But, for the other centers, do you want me to generate a list of *all* infants who are missing the ROP outcome, or just continue to send reminders for those who have *not* been coded as lost?

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

Also, you mentioned on Monday's phone call that you would like me to generate the missing outcomes report this week. That is fine, but I wanted to double-check that was what you wanted since the reports were generated last week (and generally we do them every 2 weeks).

Thanks,
Marie

Subject: RE: NeoProM Data query
Date: Thursday, October 01, 2009 1:06:52 PM

Was this part of the original data request? I don't remember whether we discussed this before; perhaps we need direction from the steering committee. However, since multiple births are design variables for our study, I don't see how they can do any analysis without that information.

Thanks

Abhik

Subject: RE: NeoProM Data query

Kylie,

We do have information on birth order and sibling match in our data; however, there is a question of whether we can share that information due to privacy issues. For example, if there is a set of quadruplets that might be a rare enough occurrence that sharing the information would make the infants identifiable. There is the additional complication that cases of multiple births in SUPPORT were randomized as a group (the pregnancy, not the infant, was the unit of randomization). Thus, family is one of our design variables that we control for in our analyses. Abhik is currently out of the office, but when he returns we will try to resolve this issue and figure out what information we can and cannot share.

Thanks,
Marie

To: Das, Abhik
Subject: NeoProM Data query

Dear Abhik,

I have taken over from Charlene Thornton at the NHMRC CTC in assisting Lisa Askie with NeoProM. I have been reviewing a spreadsheet mapping data items (attached), and there is a note for me to double check some details of the SUPPORT trial with Marie Gantz. However, we don't seem to have Marie's email address on record. If you could please provide us with this address and forward her this email that would be great thank you.

The query relates to two Enrolment characteristics:

1) Birth order; and
2) Sibling match.

The spreadsheet indicates that this data is not available in the SUPPORT trial, however, Lisa has asked me to clarify this with Marie.

If you could please review the attached spreadsheet and clarify this, that would be very helpful.

Thank you and kind regards,

Kylie Hunter (on behalf of Lisa Askie)

Subject: Re: BPD edits and other issues
Date: Thursday, October 01, 2009 12:40:46 PM

Hi Marie
We will use the BPD definition - non-physiologic- as the need for oxygen at 36 weeks. We can later separately report if we like in a subsequent paper the number of infants on vents/CPAP and room air but we will not use this for the BPD assessment. We have already discussed that some of these infants were on vents/CPAP because of recent surgery etc and this will only lead to confusion. We need to be mindful of the ability to compare our results with other studies like COIN and the we should use the commonly accepted definitions for now.
We do need clarity on the true numbers for oxygen at 36 weeks and so for me, these are the primary concerns.
In addition we should clean up as well as possible the physiologic definition and allocations as well as we can. You and I had looked at the Physiologic Infants and we had agreed on their allocation. However, I am OK if others want to have another go at this
To get the best response I would suggest that you and Rose send these out together.
Thanks
Neil

Subject: RE: SUPPORT Subcommittee Meeting
Date: Thursday, October 01, 2009 3:08:00 AM

Hi Neil,

This is not a simple answer: but if you insist, 'not very comfortable.'

Question: "If an infant has a single Zone 3 exam and did not reach previous threshold or Stage 3 and did not have surgery, how comfortable would you be to say that this infant did not have significant ROP?"
Premise: one examination in zone III, not previously threshold (you imply there were other previous exams)
1a. If there never was ROP before, then adjudication may give this infant a secondary outcome of 'never threshold' (but not a primary outcome). The findings in zone III would influence this. For example, if there were stage 3 in zone III, I doubt any adjudication could be 'favorable'.

1b. If there were significant previous ROP (even stage 2) and it is now regressing and into zone III for the first time, but infant was never seen again, there is no primary outcome. Adjudication may given this infant a secondary outcome of "not serious ROP", or may give an outcome of "We'll never know."

We found that infants with some ROP or even no ROP that had zone III diagnosed, subsequently had zone II ROP diagnosed on the next examination 12% of the time. That is why we require zone III for two SEQUENTIAL examinations before we consider the infant to be 'home free'.

Hi Dale
We are looking at the data and making a final push to get the most recent information One question - If an infant has a single Zone 3 exam and did not reach previous threshold or Stage 3 and did not have surgery, how comfortable would you ne to say that this infant did not have significant ROP?
Many thanks for your willingness to be involved I can only say that for any future study, these eye outcomes will need additional thought as it relates to obtaining a final exam available to the site/study center.
Be well
Neil

Yes! The definition of BPD is oxygen and/or resp support at 36 weeks.
Thus, it is my belief that they are on respiratory support
And thus should be counted as BPD. This was the subject of
Our working group conference call yesterday.
From our work with the consensus definition and Physiologic Def,
There is some risk that babes who are in RA and cpap/vent with strictly
airway issues could Be misclassified as BPD, but this was only 3 out of
about 3400 babes in the Bench trial, and thus seems an acceptable
tradeoff to me to avoid missing those with true BPD. WE refined the
algorithm for
Diagnosis yesterday in our conference call.

I can get this set up - do we need an ophthalmologist(s) and if so, how many?

Also - one more item that has come up -

Infants who are on CPAP or some type of vent support at 36 weeks (When NG07 gets filled out for BPD)but are on room air or 21% oxygen? Should they be in the BPD group (not eligible for physio challenge because they are "too sick", but if one uses "oxygen at 36 weeks" as BPD definition, they are classified as "no BPD.")

On 9/29/09 12:52 PM, "Walsh, Michele" <Michele.Walsh@UHhospitals.org> wrote:

Hi All: Marie and I were on a conference call today regarding the algorithm for the Consensus definition and physiologic definitions of BPD.
As we talked, it became clear that there would be some cases (?? <3%) that would be special cases that are unlikely to be clearly Classified by a computer algorithm. I would propose that the SUPPORT Subcommittee form an adjudication committee to deal with those unusual cases
In the same way that Hypothermia had an adjudication committee to assign Neurodevelopmental outcomes. To provide the most integrity to the trial,
The adjudication committee would need to have the following prespecified Characteristics:

1. an odd number of members (so that ties can not occur)
2. Independent review of cases and assignment of outcomes by each

Member using an agreed upon hierarchy of data. Clear definition of When available data are insufficient to assign outcome and thus outcome Is assigned as "Lost".

3. Written submission of the outcomes to RTI by each member.

1. Assignment of the outcome by majority of the committee.
2. in cases where no clear majority outcome assignment, conference

call and discussion until outcome clearly assigned.
If the SUPPORT subcommittee decides to go forward with such a process, I would be pleased to be part of the BPD adjudication committee.

I agree that it may also be helpful to
Have an ROP adjudication committee. For example,
We have one pt who had exams up to 49 weeks
Without any ROP. Without a committee, the computer
Would see this pt as missing an outcome. There is real information
Available that can yield an outcome assessment... and thus
More information for the trial. So long as they are tracked and reported
Clearly, my thought is more information is better.

Hi Marie
Please find attached the revised manuscript which has all of Wally's changes
Please use this one when you correct the numbers etc
Thanks
If we are going to be delayed for the ROP outcomes, I think that we should consider getting this paper to NEJM first - they may have an issue receiving both of them and then we can relax as we await the ROP data
Your thoughts
Also Marie - when will Wades data be ready so that we can submit that manuscript
Thanks
Neil

Abstract

Background: The most appropriate initial and ongoing respiratory support for the extremely low birthweight infant (ELBW) has not been established by adequate prospective evidence. The current usual approaches include the early use of continuous positive airway pressure (CPAP) or the early administration of surfactant following endotracheal intubation.

Methods: The SUPPORT study was a randomized multicenter factorial trial that enrolled consented preterm infants of 24 0/7ths weeks to 27 6/7ths weeks by best obstetrical estimate within 2 prospective strata, 24 to 25 6/7ths weeks and 26 to 27 6/7th weeks. Infants were randomized to CPAP initiated in the delivery room and were subsequently treated using a permissive strategy allowing higher PaCO2s and extubation at higher ventilator settings. Infants randomized to surfactant were intubated and received surfactant within 60 min minutes of birth. All infants were also randomized to one of 2 ranges of SpO2 while in the NICU and receiving supplemental oxygen, a low target range of 85% to 89% and a high target range of 91% to 95% using specifically altered blinded oximeters.

Results: The study enrolled 1317 infants from January 1 2004 to March 1 2009. There were 565 infants enrolled in the lower gestational age strata, and 751 in the higher strata. In the delivery room, 66% of the CPAP infants received positive pressure ventilation compared with 93% of the surfactant infants, and surfactant was given to 14% of the CPAP versus 51% of the surfactant group, and 67% of the CPAP infants received surfactant at any time during their hospitalization, (all $p<0.001$). The primary outcome of death or BPD, defined as the need for supplemental oxygen at 36 weeks post conceptional age was 48% versus 54%, ($p < 0.05$, when adjusted for gestational age, center and familial clustering). There was a significantly lower mortality in the 24 to 25 weeks strata for the infants in the Surfactant arm, (24% vs 32%, $p=0.03$). There were no differences overall for death in the delivery room nor any differences in length of stay, or days of oxygen for survivors, and the need for oxygen at discharge. More CPAP infants were alive and off mechanical ventilation by day 7, ($p=0.015$). All infants in the Surfactant arm were intubated, compared with only 77% of the CPAP infants required intubation during their nursery course, ($p<0.001$). There were no differences between the groups for airleaks including pneumothoraces.

Conclusions: The use of early CPAP with a permissive ventilator strategy results in a decrease in death or BPD defined as the need for oxygen at 36 weeks post conceptional age compared with the use of surfactant within 1 hour of birth and a conventional mechanical ventilation approach. There were no increased adverse outcomes in the CPAP group, and the surviving infants will be followed for a complete neurodevelopmental assessment at 18 to 22 months.

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

Early CPAP and the use of a permissive ventilator strategy is an evidence based approach for the initial respiratory support of the ELBW infant.

Introduction:

At the present time, there is no agreement as to the optimal approach to respiratory support for the extremely low birth weight (ELBW) infant following delivery. Positive End Expiratory Pressure (PEEP) has been shown to be of benefit in maintaining functional residual capacity (FRC), and continuous positive airway pressure appears beneficial during cardiopulmonary resuscitation[1]. Gregory et al in 1971 first demonstrated that the use of CPAP started at approximately 5.9 hours (+12.4hrs) for their infants < 1500 gm at birth, improved oxygenation[2] in newborn infants with respiratory distress; these observations were followed by prospective studies that demonstrated improved survival in premature infants treated with early CPAP[3]. A review of prospective studies evaluating early (not delivery room) CPAP in the pre-surfactant, pre-antenatal steroid era found that early CPAP improved survival overall and for infants greater than 1500 gm, and was associated with increased pneumothoraces.[4] A more recent review of prophylactic CPAP started in the delivery room reviewed only 2 available trials and found no significant difference between the CPAP and conventionally managed infants and noted a trend to increased adverse outcomes for the CPAP treated infants.[5]

There is substantial retrospective evidence suggesting a benefit for early CPAP in experiences from both the US and other countries.[67] These reports have documented a decrease in the need for mechanical ventilation among very preterm infants without an increase in morbidity following the initiation of early CPAP treatment.[8910]

The current available evidence demonstrates that prophylactic and early surfactant treatment at less than 2 hours of life significantly decreases mortality, air leak, and BPD in preterm infants.[1112] Overall surfactant has not been reported to significantly reduce BPD, but may do so for the most immature infants and has not been found to significantly reduce subsequent neurodevelopmental impairment (NDI).[13]

The recent COIN trial randomized 610 infants from 25 weeks 0 days to 28 weeks 6 days gestational age at birth, who were able to breathe at 5 minutes of age and had evidence of respiratory distress at that time. Infants were randomized to either intubation and ventilation

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

or CPAP at 8 cm H20. CPAP infants were intubated if they met failure criteria.[14] This study did not compare early CPAP to the early administration of surfactant, and surfactant use followed unit standard of care. There was a significant primary increase in the occurrence of pneumothoraces in the CPAP group (9.1% vs 3.0%, p=.001), most occurring within the first 2 days, consistent with the findings of an earlier meta analyses~~4~~6, and a reduction in death or the need for oxygen at 28 days in the CPAP infants (odds ratio, 0.63; 95% CI, 0.46 to 0.88; P=0.006) with no difference in death or BPD at 36 weeks.

In view of the current interest in the use of early CPAP and the lack of prospective comparisons of this approach with the evidence based intervention of prophylactic or early surfactant, the SUPPORT study was designed to compare these approaches for the most preterm infants. We also randomized infants to 2 ranges of pulse oximetry targets during their exposure to oxygen using a factorial design, and the results for the oximetry study will be reported separately.

Methods

This was a randomized, factorial 2X2 design multi-center trial conducted by the NICHD Neonatal Research Network. This report describes the prospective comparison of CPAP and a permissive ventilatory strategy begun in the delivery room and continuing in the NICU with the early (< 1 hour) intratracheal administration of surfactant followed by conventional mechanical ventilation.

Infants were also randomized to a prospective comparison of a lower SpO2 range (85% to 89%) with a higher more conventional SpO2 range (91% to 95%) until the infant was no longer requiring ventilatory support or oxygen using purpose altered oximeters. These results will be separately reported.

The primary hypothesis of this trial was that relative to infants managed with prophylactic/early surfactant and conventional ventilation that the use of early CPAP and a permissive ventilatory strategy in infants of 24 to 28 weeks gestation with continuing CPAP in the NICU will result in an increased survival without BPD at 36 weeks.

Eligible infants were 24 0/7ths to 27 6/7th weeks at birth by best obstetrical estimate, born at a randomizing center, for which a decision had been made to provide full resuscitation, without known malformations, and for whom parental consent had been obtained. The infants were randomized to 2 gestational age strata, 24 0/7ths to 25 6/7ths weeks, and 26 0/7ths-27 6/7ths weeks.

CPAP Arm - Delivery room management: A T-piece resuscitator, a neonatal ventilator, or an equivalent CPAP methodology was used at all sites for the delivery room administration of CPAP. CPAP or ventilation with PEEP both at a recommended 5 cm H_2O was utilized if the infant required positive pressure during resuscitation. CPAP was continued until admission to the NICU using the T-piece resuscitator or equivalent device and a face mask or nasal prongs. CPAP infants were not to be intubated for surfactant only in the DR, and CPAP infants who required intubation for resuscitation were to receive surfactant within 60 minutes of birth. Intubation for these infants was performed only for the standard NRP indications including failure to respond to positive pressure ventilation (PPV) with evidence of continuing cyanosis or bradycardia, the need for chest compressions, the need to administer intratracheal medications, or other situations in which the resuscitation team determined that surfactant is urgently required.

NICU management: Intubation was performed at any time for the occurrence of repetitive apnea requiring bag and mask ventilation, clinical shock, sepsis, and/or the need for surgery. While intubation was never required by protocol, CPAP infants could be intubated if they met any of the following criteria: an FiO_2 >.50 required to maintain an indicated SpO2 $\geq$ 88% for one hour, an arterial $PaCO_2$ > 65 torr documented on a single blood gas, or hemodynamic instability defined as a low blood pressure for gestational age and/or poor perfusion, requiring volume and/or pressor support for a period of 4 hours or more. If intubated within the first 48 hours of life infants were to receive surfactant.

Extubation for CPAP infants was to be attempted within 24 hours if all of the following criteria were met: a PaCO2 < 65 torr with a pH > 7.20, an SpO2 > 88% with an FiO2 < 50%, a mean airway pressure (MAP) < 10 cm H2O, ventilator rate < 15 bpm, an amplitude < 2X MAP if on high frequency ventilation (HFV), and hemodynamically stable, and without a clinically significant patent ductus arteriosus. Re-intubation criteria were the same as those for intubation. After 3 intubations CPAP infants were treated using NICU standard of care.

Surfactant Arm: All infants were to be intubated within 1 hour of life and receive surfactant, followed by continued ventilation. All infants were to be extubated within 24 hours of meeting all of the following criteria: $PaCO_2$ < 50 torr and pH > 7.30 An FiO2 $\leq$ 35 with a SpO2 > 88%, a mean airway pressure (MAP) < 8 cm H_2O, ventilator rate $\leq$ 15 bpm, an amplitude < 2X MAP if on high frequency ventilation (HFV), and be hemodynamically stable with no evidence of clinically significant PDA. Once extubated Surfactant infants were treated using NICU standard of care.

These criteria were in effect for the first 14 days of life, following which the infant was treated as per NICU standard of care. For both arms of the trial intubation could be performed at any

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

time for the occurrence of repetitive apnea requiring bag and mask ventilation, clinical shock, sepsis, and/or the need for surgery.

Randomization was stratified by gestational age group, utilizing specially prepared double-sealed envelopes. Deliveries were randomized as a unit, and thus multiples, were randomized to the same arm of the trial.

Hypothesis and sample size: We hypothesized that early CPAP would reduce the incidence of death or survival with BPD at 36 weeks, (using the NRN occurrence of death or survival with BPD of 67% using the year 2000 data), and the occurrence of death or survival with neurodevelopmental impairment (NDI) at 18 to 22 months (using the NRN occurrence of NDI of 61% using year 2000 data) by 10%. We increased the sample size by a factor of 1.12 to allow for multiples to be randomized to the same treatment as this introduced a clustering effect into the design, and increased the sample sizes by 17% to adjust for attrition after discharge and before follow-up. This resulted in a sample size of 1312 infants. This sample size was not large enough to determine an interaction effects between the 2 factorial arms.

In addition there was a prospective decision to also evaluate the occurrence of BPD using the Physiologic Definition which required an attempt at oxygen withdrawal for infants who required < 30% oxygen at 36 weeks and assigned a diagnosis of BPD to any infant who required more than 30% oxygen at 36 weeks or who required positive pressure support. [1516]

Statistical analyses: Intention-to-treat analyses were performed. The denominator used to calculate the rate of each outcome was the number of infants for whom that outcome was known. The primary analyses was a logistic regression analysis of the percent of each Group who developed their respective outcome measure of survival without BPD at 36 weeks and on the percent infants who survive without neurodevelopmental sequelae at 2 years. Adjustment was performed as pre-specified for gestational age, center and familial clustering. A two-sided P value of less than 0.05 was considered to statistically significant. An independent data safety monitoring committee reviewed the interim results, including those concerning adverse outcomes, four times. Pocock boundaries were used to develop stopping rules for interim safety monitoring.

The study was approved by Human Subjects Committees at all participating sites and RTI, the data center, and parental consent was required before delivery.

Results:

There were 1317 infants enrolled in this trial from Jan 1 2004 through to Mar 1 2009 . The trial was temporarily suspended by the DSMB because of concerns regarding the oximetry data in November 2005 but after a complete review the trial was continued in February 2006 with no protocol changes. The patient descriptive information for the CPAP versus Surfactant arms is shown in Table 1.There were 565 infants enrolled in the lower gestational age strata, and 751 in the higher strata. There were no significant differences for sex, birth weight, Apgar scores or race between the 2 groups. The Surfactant group received significantly more epinephrine in the delivery room and had a trend for higher DR mortality which was not significant.

In the delivery room, 66% of the CPAP infants received positive pressure ventilation compared with 93% of the surfactant infants, and surfactant was given to 14% of the CPAP versus 51% of the surfactant group, and 67% of the CPAP infants received surfactant at any time during their hospitalization, (all $p<0.0001$). Intubation in the DR occurred in 34% of CPAP infants compared with 93% of surfactant infants, $p<0.0001$, Table 2.

The primary outcome of death or BPD, defined as the need for supplemental oxygen at 36 weeks post conceptional age was significantly lower for the CPAP group compared with the Surfactant group, 48% versus 54%, ($p < 0.05$, when adjusted for gestational age, center and familial clustering as prespecified). Death during the hospitalization was 4% lower for the CPAP group overall, and was significantly lower in the CPAP arm for the 24 to 25 week strata. There was a non-significant reduction in the occurrence of BPD using the need for supplemental oxygen, 40% vs 44%, $p=0.27$. Using the Physiologic Definition for BPD there was no decrease in the occurrence of BPD in the CPAP group (40% vs 41%, $p=0.96$), and a non-significant reduction in the occurrence of death or Physiologic BPD at 36 weeks in the CPAP group, (48% vs 51%, $p=0.32$).

There were no differences overall for death in the delivery room nor any differences in length of stay, or days of oxygen for survivors, and the need for oxygen at discharge. (Table 3). More CPAP infants were alive and off mechanical ventilation by day 7, ($p=0.01$). There were no differences between the groups in air leaks in the first 14 days, airleaks during the hospital stay, medical or surgical NEC, PDA requiring surgery, or severe IVH. All infants in the Surfactant arm were intubated, compared with 83% of the CPAP infants who required intubation during their nursery course, ($p<0.0001$). There was a significant reduction in the use of postnatal steroids for BPD in the CPAP infants compared with the Surfactant infants, 7% vs 13%, $p<.001$).

Strata Results: 24 – 25 weeks Gestation

There were significantly more non-Hispanic black infants in the CPAP group compared with the Surfactant group. The differences are shown in Table 4 (24-25 wk Strata). CPAP infants had a significantly lower mortality 24% vs 32%, $p=0.03$. There was a significantly higher exposure to

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

postnatal steroids for BPD, 21% vs 13%, p=0.02 for the Surfactant group, and there were more infants alive and off mechanical ventilation at 1 week in the CPAP infants in this strata.

26-27 weeks Gestation

There was no difference in mortality for the CPAP vs Surfactant groups, 10% vs 11%. The CPAP infants required fewer days of oxygen, 36.8 vs 46.5, p<0.01, lesser days of mechanical ventilation, 10.7 vs 14.2, p<0.01, and less postnatal steroids for BPD, 3% vs 8%, p<0.01.

Discussion:

The SUPPORT trial is the first multicenter trial to compare early CPAP with early surfactant given within an hour of life in ELBW infants. The current trial is the largest study reported to prospectively compare the use of early CPAP and early surfactant for the ELBW infant and the only study to include infants of 24 weeks gestation. In a preliminary study we found that 100% of infants of 23 weeks gestation required intubation in the DR, and thus decided that such infants would be unlikely to be successfully treated with CPAP alone following delivery.[17] Others have retrospectively reported that some of these infants can be successfully managed with early CPAP, but the majority of such infants require intubation.[18]

Our study differs from the recently reported COIN trial[14][14] in that we randomized all eligible ELBW infants of consenting families irrespective of whether they demonstrated spontaneous breathing, included infants of 24 weeks gestation and compared the CPAP/permissively ventilated infants with infants who all received surfactant within 1 hour of birth. Our method of using early CPAP and a permissive ventilation strategy was a result of previous retrospective reviews of practice which demonstrated that the unit with the most success using CPAP also utilized a very permissive approach for intubation and the initiation of mechanical ventilation. **Error! Bookmark not defined.**[8] We believed that testing this complete approach would provide a more relevant result as most units currently using early CPAP also tend to be permissive in their use of intubation.

Formatted: Font: 12 pt, Superscript

Our study has demonstrated that early CPAP and a permissive ventilator strategy when compared with surfactant given within 1 hour of birth is associated with a significant reduction in death or survival with BPD as defined by the need for oxygen at 36 weeks from 54% to 48%. We also noted a very significant 8% reduction in death in our 24 to 25 week strata, resulting in a number needed to treat of 12.5 for each additional survivor. The group of 565 infants in our 24 to 25 week strata to our knowledge represents the largest prospective group of such immature infants to be randomized in any neonatal trial evaluating respiratory interventions. We believe that this lower incidence of death in these infants along with a reduction of BPD and decreased durations of ventilation and exposure to post natal steroids in the overall CPAP group represents a substantial clinical benefit compared with the initial use of early surfactant.

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

Our rates of BPD are higher than those reported for the COIN trial, 33.9% vs 38.9%, but the difference between the arms is very similar. The higher rates seen in our study no doubt reflect the inclusion of infants of 24 weeks gestation and the lack of inclusion of infants greater than 27 6/7ths weeks, as well as the requirement in the COIN trial that the infants demonstrate adequate spontaneous breathing at 5 minutes of life.

We prospectively identified a number of safety outcomes that we chose to follow as investigators. These included the need for compressions in the delivery room, the occurrence of severe IVH, and the incidence of airleaks, initially defined as pneumothoraces but later altered to include pulmonary interstitial emphysema, pneumomediastinum and pneumopericardium. We did not find an increase in airleaks with the use of early CPAP at 5 cm H2O compared to the use of early surfactant.

The SUPPORT study was designed as a factorial design with each infant randomly receiving 2 interventions, CPAP vs Surfactant, and a lower versus higher SpO2 target range. While the study was not powered to detect an interaction between the 2 interventions, we did prospectively agree to evaluate such interactions and none were found. Both arms of the study were adequately powered for both the outcomes at neonatal discharge and the occurrence of survival NDI at 18 to 22 months and these results will be presented after all survivors have been assessed.

Conclusions:

ELBW infants between 24 and 27 6/7ths weeks gestation at birth treated with CPAP and a permissive ventilator strategy compared with the use of surfactant within 1 hour of birth and conventional mechanical ventilation have a decreased incidence of death or survival with BPD based on the need for oxygen at 36 weeks PCA with no demonstrable increase in any adverse neonatal outcomes. Early CPAP with a permissive ventilator strategy is associated with a significant reduction in mortality in the most immature infants. Surviving infants will have a complete neurodevelopmental evaluation at 18 to 22 months and these results will be separately reported.

Wally
I looked this over and have to admit it is hard writing not knowing what the data will shiow.
Comments -
Page 4 - second paragraph - pulse ox's have been in NICUs more than 20 years (remove "recent").
Page 6 - patients - change "decision to forgo "support" to "resuscitation"
Page 6 - ok to say we used Masimo oximeters (and location of purchase).
Sat alarm ranges (less than or equal to 84 and greater than or equal to 96, right?)
ROP assessments - don't we need a minimum number of clock hours of disease?
Avastin was,kt a predefined outcome, bt we did collect the data.
Page 8 power analysis - do Marie's comments mirror the protocol?
For results, we can say the enrollemnt was temporarily paused after evaluation by DSMC and decision of NICHD director (the language on clintrials.gov is good). Again for restarting the trial (nichd director).
How is pvl data determined (this is impt as we will separately want to report the neuroimaging and would like consistency).
Thanks - more to come once we have data!!
Rose

Hi Neil:

Enclosed are my tracked suggestions.

In addition a few comments:

1. I think the abstract is a bit long.
2. The use of decimals in the p values is usually restricted to 3 (e.g. $P < 0.001$ not $P < 0.0001$).
3. You may want to change from "need of O2" to "on O2".

Way to go!
wally

Abstract

Background: The most appropriate initial and ongoing respiratory support for the extremely low birthweight infant (ELBW) has not been established by adequate prospective evidence. The current usual approaches include the early use of continuous positive airway pressure (CPAP) or the early administration of surfactant following endotracheal intubation.

Methods: The SUPPORT study was a randomized multicenter factorial trial that enrolled consented preterm infants of 24 0/7ths weeks to 27 6/7ths weeks by best obstetrical estimate within 2 prospective strata, 24 to 25 6/7ths weeks, and 26 to 27 6/7th weeks. Infants randomized to CPAP ~~were treated with CPAP~~ initiated in the delivery room and were subsequently treated using a permissive strategy allowing higher PaCO2s and extubation at higher ventilator settings. Infants randomized to surfactant were intubated and received surfactant within 60 min minutes of birth. All infants were also randomized to one of 2 ranges of SpO2 while in the NICU and receiving supplemental oxygen, a -low target range of 85% to 89% and a high target range of 91% to 95% using specifically altered blinded oximeters.

Results: The study enrolled 1317 infants from February 2005 to February 2009. There were 565 infants enrolled in the lower gestational age strata, and 751 in the higher strata. In the delivery room, 66% of the CPAP infants received positive pressure ventilation compared with 93% of the surfactant infants, and surfactant was given to 14% of the CPAP versus 51% of the surfactant group, and 67% of the CPAP infants received surfactant at any time during their hospitalization, (all p<0.001). The primary outcome of death or BPD, defined as the need for supplemental oxygen at 36 weeks post conceptional age was 48% versus 54%, (p < 0.05, when adjusted for gestational age, center and familial clustering). There was a significantly lower mortality in the 24 to 25 weeks strata for the infants in the Surfactant arm, (24% vs 32%, p=0.03). There were no differences overall for death in the delivery room nor any differences in length of stay, or days of oxygen for survivors, and the need for oxygen at discharge. More CPAP infants were alive and off mechanical ventilation by day 7, (p=0.015). All infants in the Surfactant arm were intubated, compared with only 77% of the CPAP infants required intubation during their nursery course, (p<0.001). There were no differences between the groups for airleaks including pneenumothoraces.

~~The primary outcome of death or BPD, defined as the need for supplemental oxygen at 36 weeks post conceptional age was 48% versus 54%, (p < 0.05, when adjusted for gestational age, center and familial clustering). There was a significantly lower mortality in the 24 to 25 weeks strata for the infants in the Surfactant arm, (24% vs 32%, p=0.03).~~

Conclusions: The use of early CPAP with a permissive ventilator strategy results in a decrease in death or ~~survival with~~ BPD defined as the need for oxygen at 36 weeks post conceptional age compared with the use of surfactant within 1 hour of birth and a conventional mechanical ventilation approach. There were no increased adverse outcomes in the CPAP group, and the surviving infants will be followed for a complete neurodevelopmental assessment at 18 to 22 months. Early CPAP and the use of a permissive ventilator strategy is an evidence based approach for the initial respiratory support of the ELBW infant.~~,~~

Neil:

I think the abstract is a bit long but it can be shortened later if needed.

Introduction:

At the present time, there is no agreement as to the optimal approach to respiratory support for the extremely low birth weight (ELBW) infant following delivery. Positive End Expiratory Pressure (PEEP) has been shown to be of benefit in maintaining functional residual capacity (FRC), and continuous positive airway pressure appears beneficial during cardiopulmonary resuscitation[1]. Gregory et al in 1971 first demonstrated that the use of CPAP started at approximately 5.9 hours (+12.4hrs) for their infants < 1500 gm at birth, improved oxygenation[2] in newborn infants with respiratory distress; these observations were followed by prospective studies that demonstrated improved survival in premature infants treated with early CPAP[3]. A review of prospective studies evaluating early (not delivery room) CPAP in the pre-surfactant, pre-antenatal steroid era found that early CPAP improved survival overall and for infants greater than 1500 gm, and was associated with increased pneumothoraces.[4] A more recent review of prophylactic CPAP started in the delivery room reviewed only 2 available trials and found no significant difference between the CPAP and conventionally managed infants and noted a trend to increased adverse outcomes for the CPAP treated infants.[5]

There is substantial retrospective evidence suggesting a benefit for early CPAP in experiences from both the US and other countries.[6,7] These reports have documented a decrease in the need for mechanical ventilation among very preterm infants without an increase in morbidity following the initiation of early CPAP treatment.[8,9,10]

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

The current available evidence demonstrates that prophylactic and early surfactant treatment at less than 2 hours of life significantly decreases mortality, air leak, and BPD in preterm infants.[1112] Overall surfactant has not been reported to significantly reduce BPD, but may do so for the most immature infants and has not been found to significantly reduce subsequent neurodevelopmental impairment (NDI).[13]

The recent COIN trial randomized 610 infants from 25 weeks 0 days to 28 weeks 6 days gestational age at birth, who were able to breathe at 5 minutes of age~~,~~ and had evidence of respiratory distress at that time. Infants were randomized to either intubation and ventilation or CPAP at~~received~~ 8 cm H20. CPAP infants were intubated if they met failure criteria.[14] This study did not compare early CPAP to the early administration of surfactant, and surfactant use followed unit standard of care. There was a significant primary increase in the occurrence of pneumothoraces in the CPAP group~~, most occurring within the first 2 days~~ (9.1% vs 3.0%, p=.001), most occurring within the first 2 days, consistent with the findings of an earlier meta analyses~~46~~ , and a reduction in death or the need for oxygen at 28 days in the CPAP infants (odds ratio, 0.63; 95% CI, 0.46 to 0.88; P=0.006) with no difference in death or BPD at 36 weeks.

In view of the current interest in the use of early CPAP and the lack of prospective comparisons of this approach with the evidence based intervention of prophylactic or early surfactant, the SUPPORT study was designed to compare these approaches for the most preterm infants. We also randomized infants to 2 ranges of pulse oximetry targets during their exposure to oxygen using a factorial design, and the results for the oximetry study will be reported separately.

Methods

This was a ~~prospective,~~ randomized, factorial 2X2 design multi-center trial conducted by the NICHD Neonatal Research Network. This report describes the prospective comparison of CPAP and a permissive ventilatory strategy begun in the delivery room and continuing in the NICU with the early (< 1 hour) intratracheal administration of surfactant followed by conventional mechanical ventilation.

Infants were also randomized to a prospective comparison of a lower SpO2 range (85% to 89%) with a higher more conventional SpO2 range (91% to 95%) until the infant was no longer requiring ventilatory support or oxygen -using purpose altered oximeters. These results will be separately reported.

The primary hypothesis of this trial~~study~~ was that relative to infants managed with prophylactic/early surfactant and conventional ventilation that the use of early CPAP and a

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

permissive ventilatory strategy in infants of 24 to ~~less than~~ 28 weeks gestation with continuing CPAP in the NICU will result in an increased survival without BPD at 36 weeks.

Eligible infants were ~~-~~24 0/7ths to 27 6/7th weeks at birth by best obstetrical estimate, born at a randomizing center, for which a decision has ~~-~~ been made to provide full resuscitation, without known malformations, and for whom parental consent had been obtained. The infants were randomized to ~~-~~2 gestational age strata, 24 0/7ths to 25 6/7ths weeks, and 26 0/7ths~~-~~27 6/7ths weeks.

CPAP Arm - Delivery room management: A T-piece resuscitator, a neonatal ventilator, or an equivalent CPAP methodology was used at all sites for the delivery room administration of CPAP. CPAP or ventilation with PEEP both at a recommended 5 cm H_2O was utilized if the infant required positive pressure during resuscitation. CPAP was continued until admission to the NICU using the ~~Neopuff~~ T-piece resuscitator or equivalent device and a face mask or nasal prongs. CPAP infants were not to be intubated for surfactant only in the DR, and CPAP infants who required intubation for resuscitation were to receive surfactant within 60 minutes of birth. Intubation for these infants was performed only for the standard NRP indications including failure to respond to positive pressure ventilation (PPV) with evidence of continuing cyanosis or bradycardia, the need for chest compressions, the need to administer intratracheal medications, or other situations in which the resuscitation team determined that surfactant is urgently required.

NICU management: Intubation was performed at any time for the occurrence of repetitive apnea requiring bag and mask ventilation, clinical shock, sepsis, and/or the need for surgery~~-~~. While intubation was never required by protocol, CPAP infants could be intubated if they met any of the following criteria: an FiO_2 >.50 required to maintain an indicated SpO2 $\geq$ 88% for one hour, ~~-~~an arterial $PaCO_2$ > 65 torr documented on a single blood gas, or hemodynamic instability defined as a low blood pressure for gestational age and/or poor perfusion, requiring volume and/or pressor support for a period of 4 hours or more. If intubated within the first 48 hours of life infants were to receive surfactant.

Extubation for CPAP infants was to be attempted within 24 hours if all of the following criteria were met: a PaCO2 < 65 torr with a pH > 7.20, an SpO2 > 88% with an FiO2 < 50%~~-~~, a mean airway pressure (MAP) < 10 cm H2O, ventilator rate < 15 bpm, an amplitude < 2X MAP if on high frequency ventilation (HFV), and hemodynamically stable, and without a clinically significant patent ductus arteriosus. Re-intubation criteria were the same as those for i~~I~~ntubation ~~for the CPAP infants~~. After 3 intubations CPAP infants were treated using NICU standard of care.

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

Surfactant Arm: All infants were to be intubated within 1 hour of life and receive surfactant, followed by continued ventilation. All infants were to be extubated within 24 hours of meeting all of the following criteria: $PaCO_2 < 50$ torr and pH > 7.30 An FiO2 ≤ 35 with a SpO2 > 88%, a mean airway pressure (MAP) < 8 cm H_2O, ventilator rate ≤ 15 bpm, an amplitude < 2X MAP if on high frequency ventilation (HFV), and be hemodynamically stable with no evidence of clinically significant PDA. Once extubated Surfactant infants were treated using NICU standard of care.

These criteria were in effect for the first 14 days of life, following which the infant was treated as per NICU standard of care. For both arms of the trial intubation could be performed at any time for the occurrence of repetitive apnea requiring bag and mask ventilation, clinical shock, sepsis, and/or the need for surgery.

Randomization was stratified by gestational age group, utilizing specially prepared double-sealed envelopes. Deliveries were randomized as a unit, and thus multiples, were randomized to the same arm of the trial.

Hypothesis and sample size: We hypothesized that early CPAP would reduce the incidence of death or survival with BPD at 36 weeks, (using the NRN occurrence of death or survival with BPD of 67% using the year 2000 data), and the occurrence of death or survival with neurodevelopmental impairment (NDI) at 18 to 22 months (using the NRN occurrence of NDI of 61% using year 2000 data) by 10%. We increased the sample size by a factor of 1.12 to allow for multiples to be randomized to the same treatment as this introduced a clustering effect into the design, and increased the sample sizes by 17% to adjust for attrition after discharge and before follow-up. This resulted in a sample size of 1312 infants. This sample size was not large enough to determine an interaction effects between the 2 factorial arms.

In addition there was a prospective decision to also evaluate the occurrence of BPD using the Physiologic Definition which required an attempt at oxygen withdrawal for infants who required < 30% oxygen at 36 weeks and assigned a diagnosis of BPD to any infant who required more than 30% oxygen at 36 weeks or who required positive pressure support. [1516]

Statistical analyses: Intention-to-treat analyses were performed. The denominator used to calculate the rate of each outcome was the number of infants for whom that outcome was known. The primary analyses was a logistic regression analysis of the percent of each Group who developed their respective outcome measure of survival without BPD at 36 weeks and on the percent infants who survive without neurodevelopmental sequelae at 2 years. Adjustment was performed as pre-specified for gestational age, center and familial clustering. A two-sided P value of less than 0.05 was considered to statistically significant. An independent data safety monitoring committee reviewed the interim results, including those concerning adverse

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

outcomes, four times. Pocock boundaries were used to develop stopping rules for interim safety monitoring.

The study was approved by Human Subjects Committees at all participating sites and RTI, the data center, and parental consent was required before delivery.

Results:

There were 1317 infants enrolled in this trial from Jan 1 2004 through to Mar 1 2009 (you use different dates than the abstract). The trial was temporarily suspended by the DSMB because of concerns regarding the oximetry data in November 2005 but after a complete review the trial was continued in February 2006 with no protocol changes. The patient descriptive information for the CPAP versus ~~Early~~ Surfactant arms is shown in Table 1.There were 565 infants enrolled in the lower gestational age strata, and 751 in the higher strata. There were no significant differences for sex, birth weight, Apgar scores or race between the 2 groups~~, although there were more boys in the CPAP arm, p=.056~~. The Surfactant group received significantly more epinephrine in the delivery room and had a trend for higher DR mortality which was not significant.

In the delivery room, 66% of the CPAP infants received positive pressure ventilation compared with 93% of the surfactant infants, and surfactant was given to 14% of the CPAP versus 51% of the surfactant group, and 67% of the CPAP infants received surfactant at any time during their hospitalization, (all $p<0.0001$). Intubation in the DR occurred in 34% of CPAP infants compared with 93% of surfactant infants, $p<0.0001$, Table 2.

The primary outcome of death or BPD, defined as the need for supplemental oxygen at 36 weeks post conceptional age was significantly lower for the CPAP group compared with the Surfactant group, 48% versus 54%, ($p < 0.05$, when adjusted for gestational age, center and familial clustering as prespecified). Death during the hospitalization was 4% lower for the CPAP group overall, and was significantly lower in the CPAP arm the 24 to 25 week strata even after adjustment which included gender. There was a non-significant reduction in the occurrence of BPD using the need for supplemental oxygen, 40% vs 44%, p=0.27. Using the Physiologic Definition for BPD there was no~~a non significant~~ decrease in the occurrence of BPD in the CPAP group (-40% vs 41%, p=0.96), and a non-significant reduction in the occurrence of death or Physiologic BPD at 36 weeks in the CPAP group, (48% vs 51%, p=0.32).

There were no differences overall for death in the delivery room nor any differences in length of stay, or days of oxygen for survivors, and the need for oxygen at discharge. (Table 3). More CPAP infants were alive and off mechanical ventilation by day 7, (p=0.0149). ~~We prospectively~~

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

~~recorded~~ T~~air leaks in the first 14 days and t~~here were no differences between the groups~~, and no differences~~ in~~for~~ air leaks in the first 14 days, airleaks during the hospital stay, medical or surgical NEC, PDA requiring surgery, or severe IVH~~ or airleaks during the hospital stay~~. All infants in the Surfactant arm were intubated, compared with 83% of the CPAP infants who required intubation during their nursery course, ($p<0.0001$). There was a significant reduction in the use of postnatal steroids for BPD in the CPAP infants compared with the Surfactant infants, 7% vs 13%, $p=0.0004$).

~~Death during the hospitalization was 4% lower for the CPAP group overall, and was significantly lower in the CPAP arm the 24 to 25 week strata even after adjustment which included gender.~~

Strata Results: 24 – 25 weeks Gestation

There were significantly more non-Hispanic black infants in the CPAP group compared with the Surfactant group. The differences are shown in Table 4 (24-25 wk Strata). CPAP infants had a significantly lower mortality 24% vs 32%, $p=0.03$. There was a significantly higher exposure to postnatal steroids for BPD, 21% vs 13%, $p=0.02$ for the Surfactant group, and there were more infants alive and off mechanical ventilation at 1 week in the CPAP infants in this strata.

26-27 weeks Gestation

There was no difference in mortality for the CPAP vs Surfactant groups, 10% vs 11%. The CPAP infants required fewer days of oxygen, 36.8 vs 46.5, $p<0.01$, lesser days of mechanical ventilation, 10.7 vs 14.2, $p<0.01$, and less postnatal steroids for BPD, 3% vs 8%, $p<0.01$.

Discussion:

The SUPPORT trial is the first ~~large~~ multicenter trial~~study~~ to ~~prospectively~~ compare early CPAP~~,~~ with early surfactant given within an hour of life in ~~to a large group of~~ ELBW infants. The current trial is the largest study reported to prospectively compare the use of early CPAP and early surfactant for the ELBW infant and the only study to include infants of 24 weeks gestation. In a preliminary study we found that 100% of infants of 23 weeks gestation required intubation in the DR, and thus decided that such infants would be unlikely to be successfully treated with CPAP alone following delivery.[17] Others have retrospectively reported that some of these infants can be successfully managed with early CPAP, but the majority of such infants require intubation.[18]

Our study differs from the recently reported COIN trial[14~~14~~] in that we randomized all eligible ELBW infants of consenting families irrespective of whether they demonstrated spontaneous breathing, included infants of 24 weeks gestation~~,~~ and compared the CPAP/permissively ventilated infants with infants who all received surfactant within 1 hour of birth. Our

methodology of using early CPAP and a permissive ventilation strategy was a result of previous retrospective reviews of practice which demonstrated that the unit with the most success using CPAP also utilized a very permissive approach for intubation and the initiation of mechanical ventilation. **Error! Bookmark not defined.**8 We believed that testing this complete approach would be provide a more relevant result as most units currently using early CPAP also tend to be permissive in their use of intubation.

Our study has demonstrated that early CPAP and a permissive ventilator strategy when compared with surfactant given within 1 hour of birth is associated with a reduction in death or survival with BPD as defined by the need for oxygen at 36 weeks from 54% to 48%. As with any prospective randomized trial differences may exist in baseline characteristics and we noted more males in our Surfactant arm although this difference failed to reach significance. We believed that the clinical significance of this difference was relevant and chose to further adjust our results for gender which resulted in a loss of significance for our primary outcome variable using the definition of BPD as requiring oxygen at 36 weeks age. However we also noted a very significant 8% reduction in death in our 24 to 25 week strata, resulting in a number needed to treat of 12.5 for each additional survivor. The group of 565 infants in our 24 to 25 week strata to our knowledge represents the largest prospective group of such immature infants to be randomized in any neonatal trial evaluating respiratory interventions. We believe that this lower incidence of death in these infants along with a reduction of BPD and decreased durations of ventilation and exposure to post natal steroids in the overall CPAP group represents a substantial clinical benefit compared with the initial use of early surfactant.

Our rates of BPD are higher than those reported for the COIN trial, 33.9% vs 38.9%, but the difference between the arms is very similar. The higher rates seen in our study no doubt reflect the inclusion of infants of 24 weeks gestation and the lack of inclusion of infants greater than 27 6/7ths weeks, as well as the requirement in the COIN trial that the infants demonstrate adequate spontaneous breathing at 5 minutes of life.

We prospectively identified a number of safety outcomes that we chose to follow as investigators. These included the need for compressions in the delivery room, the occurrence of severe IVH, and the incidence of airleaks, initially defined as pneumothoraces but later altered to include pulmonary interstitial emphysema, pneumomediastinum and pneumopericardium. We did not find an increase in airleaks with the use of early CPAP at 5 cm H2O compared to the use of early surfactant.

The SUPPORT study was designed as a factorial design with each infant randomly receiving 2 interventions, CPAP vs Surfactant, and a lower versus higher SpO2 target range. While the study was not powered to detect an interaction between the 2 interventions, we did prospectively agree to evaluate such interactions and none were found. Both arms of the study were

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

adequately powered for both the outcomes at neonatal discharge and the occurrence of survival NDI at 18 to 22 months and these results will be presented after all survivors have been assessed.

Conclusions:

ELBW infants between 24 and 27 6/7ths weeks gestation at birth treated with CPAP and a permissive ventilator strategy compared with the use of surfactant within 1 hour of birth and conventional mechanical ventilation have a decreased incidence of death or survival with BPD based on the need for oxygen at 36 weeks PCA with no demonstrable increase in any adverse neonatal outcomes. Early CPAP with~~and~~ a permissive ventilator strategy is associated with a significant reduction in mortality in the most immature infants. Surviving infants will have a complete neurodevelopmental evaluation at 18 to 22 months and these results will be separately reported.

Abstract

Background: The most appropriate initial and ongoing respiratory support for the extremely low birthweight infant (ELBW) has not been established by adequate prospective evidence. The current usual approaches include the early use of continuous positive airway pressure (CPAP) or the early administration of surfactant following endotracheal intubation.

Methods: The SUPPORT study was a randomized multicenter factorial trial that enrolled consented preterm infants of 24 0/7ths weeks to 27 6/7ths weeks by best obstetrical estimate within 2 prospective strata, 24 to 25 6/7ths weeks, and 26 to 27 6/7th weeks. Infants randomized to CPAP were treated with CPAP initiated in the delivery room and were subsequently treated using a permissive strategy allowing higher PaCO2s and extubation at higher ventilator settings. Infants randomized to surfactant were intubated and received surfactant within 60 min minutes of birth. All infants were also randomized to one of 2 ranges of SpO2 while in the NICU and receiving supplemental oxygen, a low target range of 85% to 89% and a high target range of 91% to 95% using specifically altered blinded oximeters.

Results: The study enrolled 1317 infants from February 2005 to February 2009. There were 565 infants enrolled in the lower gestational age strata, and 751 in the higher strata. In the delivery room, 66% of the CPAP infants received positive pressure ventilation compared with 93% of the surfactant infants, and surfactant was given to 14% of the CPAP versus 51% of the surfactant group, and 67% of the CPAP infants received surfactant at any time during their hospitalization, (all $p<0.001$). There were no differences overall for death in the delivery room nor any differences in length of stay, or days of oxygen for survivors, and the need for oxygen at discharge. More CPAP infants were alive and off mechanical ventilation by day 7, ($p=0.015$). All infants in the Surfactant arm were intubated, compared with only 77% of the CPAP infants required intubation during their nursery course, ($p<0.001$). There were no differences between the groups for airleaks including penumothoraces. The primary outcome of death or BPD, defined as the need for supplemental oxygen at 36 weeks post conceptional age was 48% versus 54%, ($p < 0.05$, when adjusted for gestational age, center and familial clustering). There was a significantly lower mortality in the 24 to 25 weeks strata for the infants in the Surfactant arm, (24% vs 32%, $p=0.03$).

Conclusions: The use of early CPAP with a permissive ventilator strategy results in a decrease in death or survival with BPD defined as the need for oxygen at 36 weeks post conceptional age compared with the use of surfactant within 1 hour of birth and a conventional mechanical ventilation approach. There were no increased adverse outcomes in the CPAP group, and the surviving infants will be followed for a complete neurodevelopmental assessment at 18 to 22

months. Early CPAP and the use of a permissive ventilator strategy is an evidence based approach for the initial respiratory support of the ELBW infant.

Introduction:

At the present time, there is no agreement as to the optimal approach for the extremely low birth weight (ELBW) infant following delivery. Positive End Expiratory Pressure (PEEP) has been shown to be of benefit in maintaining functional residual capacity (FRC) and continuous positive airway pressure appears beneficial during cardiopulmonary resuscitation[1]. Gregory et al in 1971 first demonstrated that the use of CPAP started at approximately 5.9hours (+12.4hrs) for their infants < 1500 gm at birth, improved oxygenation[2] in newborn infants with respiratory distress; these observations were followed by prospective studies that demonstrated improved survival in premature infants treated with early CPAP[3]. A review of prospective studies evaluating early (not delivery room) CPAP in the pre-surfactant, pre-antenatal steroid era found that early CPAP improved survival overall and for infants greater than 1500 gm, and was associated with increased pneumothoraces.[4] A more recent review of prophylactic CPAP started in the delivery room reviewed only 2 available trials and found no significant difference between the CPAP and conventionally managed infants and noted a trend to increased adverse outcomes for the CPAP treated infants.[5]

There is substantial retrospective evidence suggesting a benefit for early CPAP in experiences from both the US and other countries.[67] These reports have documented a decrease in the need for mechanical ventilation among very preterm infants without an increase in morbidity following the initiation of early CPAP treatment.[8910]

The current available evidence demonstrates that prophylactic and early surfactant treatment at less than 2 hours of life significantly decreases mortality, air leak, and BPD in preterm infants.[1112] Overall surfactant has not been reported to significantly reduce BPD, but may do so for the most immature infants and has not been found to significantly reduce subsequent neurodevelopmental impairment (NDI).[13]

The recent COIN trial randomized 610 infants from 25 weeks 0 days to 28 weeks 6 days gestational age at birth, who were able to breathe at 5 minutes of age, and had evidence of respiratory distress at that time. Infants were randomized to either intubation and ventilation

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

or CPAP received 8 cm H20. CPAP infants were intubated if they met failure criteria.[14] This study did not compare early CPAP to the early administration of surfactant, and surfactant use followed unit standard of care. There was a significant primary increase in the occurrence of pneumothoraces in the CPAP group, most occurring within the first 2 days (9.1% vs 3.0%, p=.001), consistent with the findings of an earlier meta analyses4 and a reduction in death or the need for oxygen at 28 days in the CPAP infants (odds ratio, 0.63; 95% CI, 0.46 to 0.88; P=0.006) with no difference in death or BPD at 36 weeks.

In view of the current interest in the use of early CPAP and the lack of prospective comparisons of this approach with the evidence based intervention of prophylactic or early surfactant, the SUPPORT study was designed to compare these approaches for the most preterm infants. We also randomized infants to 2 ranges of pulse oximetry targets during their exposure to oxygen using a factorial design, and the results for the oximetry study will be reported separately.

Methods

This was a prospective, randomized, factorial 2X2 design multi-center trial conducted by the NICHD Neonatal Research Network. This report describes the prospective comparison of CPAP and a permissive ventilatory strategy begun in the delivery room and continuing in the NICU with the early (< 1 hour) intratracheal administration of surfactant followed by conventional mechanical ventilation.

Infants were also randomized to a prospective comparison of a lower SpO2 range (85% to 89%) with a higher more conventional SpO2 range (91% to 95%) until the infant was no longer requiring ventilatory support or oxygen using purpose altered oximeters. These results will be separately reported.

The primary hypothesis of this study was that relative to infants managed with prophylactic/early surfactant and conventional ventilation that the use of early CPAP and a permissive ventilatory strategy in infants of less than 28 weeks gestation with continuing CPAP in the NICU will result in an increased survival without BPD at 36 weeks.

Eligible infants were 24 0/7ths to 27 6/7th weeks at birth by best obstetrical estimate, born at a randomizing center, for which a decision has been made to provide full resuscitation without known malformations, and for whom parental consent had been obtained. The infants were randomized to 2 gestational age strata, 24 0/7ths to 25 6/7ths weeks, and 26 0/7ths-27 6/7ths weeks.

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

CPAP Arm - Delivery room management: A T-piece resuscitator, a neonatal ventilator, or an equivalent CPAP methodology was used at all sites for the delivery room administration of CPAP. CPAP or ventilation with PEEP both at a recommended 5 cm H_2O was utilized if the infant required positive pressure during resuscitation. CPAP was continued until admission to the NICU using the Neopuff or equivalent device and a face mask or nasal prongs. CPAP infants were not to be intubated for surfactant only in the DR, and CPAP infants who required intubation for resuscitation were to receive surfactant within 60 minutes of birth. Intubation for these infants was performed only for the standard NRP indications including failure to respond to positive pressure ventilation (PPV) with evidence of continuing cyanosis or bradycardia, the need for chest compressions, the need to administer intratracheal medications, or other situations in which the resuscitation team determined that surfactant is urgently required.

NICU management: Intubation was performed at any time for the occurrence of repetitive apnea requiring bag and mask ventilation, clinical shock, sepsis, and/or the need for surgery . While intubation was never required by protocol, CPAP infants could be intubated if they met any of the following criteria: an FiO_2 >.50 required to maintain an indicated SpO2 $\geq$ 88% for one hour, an arterial $PaCO_2$ > 65 torr documented on a single blood gas, or hemodynamic instability defined as a low blood pressure for gestational age and/or poor perfusion, requiring volume and/or pressor support for a period of 4 hours or more. If intubated within the first 48 hours of life infants were to receive surfactant.

Extubation for CPAP infants was to be attempted within 24 hours if all of the following criteria were met: a PaCO2 < 65 torr with a pH > 7.20, an SpO2 > 88% with an FiO2 < 50% , a mean airway pressure (MAP) < 10 cm H2O, ventilator rate < 15 bpm, an amplitude < 2X MAP if on high frequency ventilation (HFV), and hemodynamically stable, and without a clinically significant patent ductus arteriosus. Re-intubation criteria were the same as those for Intubation for the CPAP infants. After 3 intubations CPAP infants were treated using NICU standard of care.

Surfactant Arm: All infants were to be intubated within 1 hour of life and receive surfactant, followed by continued ventilation. All infants were to be extubated within 24 hours of meeting all of the following criteria: $PaCO_2$ < 50 torr and pH > 7.30 An FiO2 $\leq$ 35 with a SpO2 > 88%, a mean airway pressure (MAP) < 8 cm H_2O, ventilator rate $\leq$ 15 bpm, an amplitude < 2X MAP if on high frequency ventilation (HFV), and be hemodynamically stable with no evidence of clinically significant PDA. Once extubated Surfactant infants were treated using NICU standard of care.

These criteria were in effect for the first 14 days of life, following which the infant was treated as per NICU standard of care. For both arms of the trial intubation could be performed at any

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

time for the occurrence of repetitive apnea requiring bag and mask ventilation, clinical shock, sepsis, and/or the need for surgery.

Randomization was stratified by gestational age group, utilizing specially prepared double-sealed envelopes. Deliveries were randomized as a unit, and thus multiples, were randomized to the same arm of the trial.

Hypothesis and sample size: We hypothesized that early CPAP would reduce the incidence of death or survival with BPD at 36 weeks, (using the NRN occurrence of death or survival with BPD of 67% using the year 2000 data), and the occurrence of death or survival with neurodevelopmental impairment (NDI) at 18 to 22 months (using the NRN occurrence of NDI of 61% using year 2000 data) by 10%. We increased the sample size by a factor of 1.12 to allow for multiples to be randomized to the same treatment as this introduced a clustering effect into the design, and increased the sample sizes by 17% to adjust for attrition after discharge and before follow-up. This resulted in a sample size of 1312 infants. This sample size was not large enough to determine an interaction effects between the 2 factorial arms.

In addition there was a prospective decision to also evaluate the occurrence of BPD using the Physiologic Definition which required an attempt at oxygen withdrawal for infants who required < 30% oxygen at 36 weeks and assigned a diagnosis of BPD to any infant who required more than 30% oxygen at 36 weeks or who required positive pressure support. [1516]

Statistical analyses: Intention-to-treat analyses were performed. The denominator used to calculate the rate of each outcome was the number of infants for whom that outcome was known. The primary analyses was a logistic regression analysis of the percent of each Group who developed their respective outcome measure of survival without BPD at 36 weeks and on the percent infants who survive without neurodevelopmental sequelae at 2 years. Adjustment was performed as pre-specified for gestational age, center and familial clustering. A two-sided P value of less than 0.05 was considered to statistically significant. An independent data safety monitoring committee reviewed the interim results, including those concerning adverse outcomes, four times. Pocock boundaries were used to develop stopping rules for interim safety monitoring.

The study was approved by Human Subjects Committees at all participating sites and RTI, the data center, and parental consent was required before delivery.

There were 1317 infants enrolled in this trial from Jan 1 2004 through to Mar 1 2009. The trial was temporarily suspended by the DSMB because of concerns regarding the oximetry data in November 2005 but after a complete review the trial was continued in February 2006 with no protocol changes. The patient descriptive information for the CPAP versus Early Surfactant arms is shown in Table 1.There were 565 infants enrolled in the lower gestational age strata, and 751 in the higher strata. There were no significant differences for sex, birth weight Apgar scores or race between the 2 groups, although there were more boys in the CPAP arm, p=.056. The Surfactant group received significantly more epinephrine in the delivery room and had a higher DR mortality which was not significant.

In the delivery room, 66% of the CPAP infants received positive pressure ventilation compared with 93% of the surfactant infants, and surfactant was given to 14% of the CPAP versus 51% of the surfactant group, and 67% of the CPAP infants received surfactant at any time during their hospitalization, (all $p<0.0001$). Intubation in the DR occurred in 34% of CPAP infants compared with 93% of surfactant infants, $p<0.0001$, Table 2.

The primary outcome of death or BPD, defined as the need for supplemental oxygen at 36 weeks post conceptional age was significantly lower for the CPAP group compared with the Surfactant group, 48% versus 54%, ($p < 0.05$, when adjusted for gestational age, center and familial clustering as prespecified). There was a non-significant reduction in the occurrence of BPD using the need for supplemental oxygen, 40% vs 44%, p=.27. Using the Physiologic Definition for BPD there was a non-significant decrease in the occurrence of BPD in the CPAP group (40% vs 41%, p=.96), and a non-significant reduction in the occurrence of death or Physiologic BPD at 36 weeks in the CPAP group, (48% vs 51%, p=.32).

There were no differences overall for death in the delivery room nor any differences in length of stay, or days of oxygen for survivors, and the need for oxygen at discharge. (Table 3). More CPAP infants were alive and off mechanical ventilation by day 7, (p=0.0149). We prospectively recorded air leaks in the first 14 days and there were no differences between the groups, and no differences for medical or surgical NEC, PDA requiring surgery, severe IVH or airleaks during the hospital stay. All infants in the Surfactant arm were intubated, compared with 83% of the CPAP infants who required intubation during their nursery course, ($p<0.0001$). There was a significant reduction in the use of postnatal steroids for BPD in the CPAP infants compared with the Surfactant infants, 7% vs13%, p=0.0004). Death during the hospitalization was 4% lower for the CPAP group overall, and was significantly lower in the CPAP arm the 24 to 25 week strata even after adjustment which included gender.

Strata Results: 24 – 25 weeks Gestation

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

There were significantly more non-Hispanic black infants in the CPAP group compared with the Surfactant group. The differences are shown in Table 4 (24-25 wk Strata). CPAP infants had a significantly lower mortality 24% vs 32%, p=0.03. There was a significantly higher exposure to postnatal steroids for BPD, 21% vs 13%, p=0.02 for the Surfactant group, and there were more infants alive and off mechanical ventilation at 1 week in the CPAP infants in this strata.

26-27 weeks Gestation

There was no difference in mortality for the CPAP vs Surfactant groups, 10% vs 11%. The CPAP infants required fewer days of oxygen, 36.8 vs 46.5, p<0.01, lesser days of mechanical ventilation, 10.7 vs 14.2, p<0.01, and less postnatal steroids for BPD, 3% vs 8%, p<0.01.

Discussion:

The SUPPORT trial is the first large multicenter study to prospectively compare early CPAP, with early surfactant given within an hour of life to a large group of ELBW infants. The current trial is the largest study reported to prospectively compare the use of early CPAP and early surfactant for the ELBW infant and the only study to include infants of 24 weeks gestation. In a preliminary study we found that 100% of infants of 23 weeks gestation required intubation in the DR, and thus decided that such infants would be unlikely to be successfully treated with CPAP alone following delivery.[17] Others have retrospectively reported that some of these infants can be successfully managed with early CPAP, but the majority of such infants require intubation.[18]

Our study differs from the recently reported COIN trial[14] in that we randomized all eligible ELBW infants of consenting families irrespective of whether they demonstrated spontaneous breathing, included infants of 24 weeks gestation, and compared the CPAP/permissively ventilated infants with infants who all received surfactant within 1 hour of birth. Our methodology of using early CPAP and a permissive ventilation strategy was a result of previous retrospective reviews of practice which demonstrated that the unit with the most success using CPAP also utilized a very permissive approach for intubation and the initiation of mechanical ventilation. **Error! Bookmark not defined.** We believed that testing this complete approach would be provide a more relevant result as most units currently using early CPAP also tend to be permissive in their use of intubation.

Our study has demonstrated that early CPAP and a permissive ventilator strategy when compared with surfactant given within 1 hour of birth is associated with a reduction in death or survival with BPD as defined by the need for oxygen at 36 weeks from 54% to 48%. As with any prospective randomized trial differences may exist in baseline characteristics and we noted more males in our Surfactant arm although this difference failed to reach significance. We believed that the clinical significance of this difference was relevant and chose to further adjust our results for gender which resulted in a loss of significance for our primary outcome variable

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

using the definition of BPD as requiring oxygen at 36 weeks age. However we also noted a very significant 8% reduction in death in our 24 to 25 week strata, resulting in a number needed to treat of 12.5 for each additional survivor. The 565 infants in our 24 to 25 week strata to our knowledge represents the largest prospective group of such immature infants to be randomized in any neonatal trial evaluating respiratory interventions. We believe that this lower incidence of death in these infants along with a reduction of BPD and decreased durations of ventilation and exposure to post natal steroids in the overall CPAP group represents a substantial clinical benefit compared with the initial use of early surfactant.

Our rates of BPD are higher than those reported for the COIN trial, 33.9% vs 38.9%, but the difference between the arms is very similar. The higher rates seen in our study no doubt reflect the inclusion of infants of 24 weeks gestation and the lack of inclusion of infants greater than 27 6/7ths weeks, as well as the requirement in the COIN trial that the infants demonstrate adequate spontaneous breathing at 5 minutes of life.

We prospectively identified a number of safety outcomes that we chose to follow as investigators. These included the need for compressions in the delivery room, the occurrence of severe IVH, and the incidence of airleaks, initially defined as pneumothoraces but later altered to include pulmonary interstitial emphysema, pneumomediastinum and pneumopericardium. We did not find an increase in airleaks with the use of early CPAP at 5 cm H2O compared to the use of early surfactant.

The SUPPORT study was designed as a factorial design with each infant randomly receiving 2 interventions, CPAP vs Surfactant, and a lower versus higher SpO2 target range. While the study was not powered to detect an interaction between the 2 interventions, we did prospectively agree to evaluate such interactions and none were found. Both arms of the study were adequately powered for both the outcomes at neonatal discharge and the occurrence of survival NDI at 18 to 22 months and these results will be presented after all survivors have been assessed.

Conclusions:

ELBW infants between 24 and 27 6/7ths weeks gestation at birth treated with CPAP and a permissive ventilator strategy compared with the use of surfactant within 1 hour of birth and conventional mechanical ventilation have a decreased incidence of death or survival with BPD based on the need for oxygen at 36 weeks PCA with no demonstrable increase in any adverse neonatal outcomes. Early CPAP and a permissive ventilator strategy is associated with a significant reduction in mortality in the most immature infants. Surviving infants will have a complete neurodevelopmental evaluation at 18 to 22 months and these results will be separately reported.

Hi Marie
Remind me from our past conversations as to how many of the infants with incomplete eye diagnoses have been seen in follow-up, or more importantly lost to follow-up
For how many infants did follow-up provide additional data for the eye outcome?
Of the 57 infants with the last exam in Zone 1 or 2, for those who have not yet been seen at follow-up can we call these families regarding whether they had any further eye exams- Have we done this??
Thanks
Neil

Attached is the list of Duke BPD queries with my comments. Some cases have been resolved and some have not. In cases where there are still inconsistencies, I have highlighted my comments in yellow. Note that there are a few cases where the infant's status on the NG03 and SUPP09 are inconsistent with each other in terms of whether the infant was transferred.

Hi,
We are getting close to having final outcomes for SUPPORT. Thanks for all your hard work. I have attached the BPD queries and an explanation for the queries to the email. In addition, we are missing the following primary outcomes for SUPPORT listed below.

Again, thanks so much for all the hard work and effort!!
Regards,
Rose

SUPPORT!!!

There are 109 infants without an ROP outcome in the SUPPORT trial (n=1317).
We need to finalize and lock the ROP data so that the analysis can proceed.
The final date for Data Entry for SUPPORT ROP is OCTOBER 20. Please insure that you have the outcomes for your infants entered by October 20!!!

Subject: RE: Oxygen saturation targeting paper

Hi all,

Thanks for your patience while I was away. I have made few edits and comments to the latest version of Wally's paper. Wally, you had mentioned that you were missing some outcomes (like IVH/death) and I believe those were included in tables I sent on Sept. 3 (T2S Major Outcomes - PRELIMINARY 03SEP09.doc) – let me know if you need me to resend them.

Regarding the earlier question about the numbers in figure 1 differing from the monthly report, in the monthly report "*Eligible GDB patients are those keyed in the NG02 (inborn and GA of 24 0/6 & 27 6/7) with a birth date after the first Support patient keyed for sites at each Center and not born on or between dates of Support study suspension 11/23/2005 and 2/5/2006*" while the 3546 in figure 1 are those infants who were entered on the SUPP01 screening log. I'm not sure what to do about the difference unless we add them to the number who were "eligible but consent not sought." We should also be clear in figure 1 that many more moms were screened than are reflected on the SUPP01, because only those infants who were eventually assigned a GDB number (or who were enrolled in SUPPORT) were entered into the DMS. We could reference Wade's antenatal consent paper for a more accurate estimate of how many moms were screened.

FYI, while I was gone, queries went out to the centers regarding data that differed across GDB and SUPPORT forms and that will impact the secondary outcomes (including things like IVH) to some (hopefully small) degree. We have heard back from 10 centers so far, and I will review the results of the queries as we get responses to make sure all the necessary data are cleaned. I will also re-review the BPD outcome data to see if those queries have been completely cleared up yet and I will remind centers of any outstanding queries.

Thanks,
Marie

Cc: Wally Carlo, M.D.
Subject: Oxygen saturation targeting paper

Dear Neil, Rose, Abhik, and Marie:

I have made several changes including:
1. Making Neil's suggestions
2. Improved Figure 2
3. Included Figure 1
4. Multiple minor changes.

I have made changes in all the numbers of the results as Abhik said they are still not final.

Enclosed is a clean draft so you can see my comments. I think we need to consider adding the ROP data if it is final before the paper is ready for submission.

I would appreciate any comments.

Thanks
Wally

Subject: RE: SUPPORT missing data updates
Date: Monday, September 28, 2009 2:00:23 PM

Here is the FU window status for infants missing ROP:

Those with lowest zone of any vessels=1 at last exam (N=2)
- 2 with closed FU windows (have not looked to see if FU visit took place)

Those with lowest zone of any vessels=2 at last exam (N=55)
- 18 with closed FU windows (have not looked to see if FU visit took place)
- 7 with windows open now
- 30 with windows not opened yet

Those with lowest zone of any vessels=3 at last exam (N=52)
- 21 with closed FU windows (have not looked to see if FU visit took place)
- 4 with windows open now
- 27 with windows not opened yet

According to the SUPP10, there were 16 cases where final ROP status was obtained at the FU visit.

Hi Marie
Remind me from our past conversations as to how many of the infants with incomplete eye diagnoses have been seen in follow-up, or more importantly lost to follow-up
For how many infants did follow-up provide additional data for the eye outcome?
Of the 57 infants with the last exam in Zone 1 or 2, for those who have not yet been seen at follow-up can we call these families regarding whether they had any further eye exams- Have we done this??
Thanks
Neil

If the data were transmitted on Thursday then we probably have it; however, our analysis datasets are only updated once a week (after the Tuesday transmissions) so that's why I did not see the new ROP data in my version of the dataset. Thanks!

Hi Karen,

The last exam we have for this infant was on 5/27/09 (entered into the DMS on 5/29) and the infant had not reached final ROP status. Perhaps the latest exam entered last week has not been transmitted yet?

Thanks,
Marie

Hi Rose,

The ROP final outcome on this baby was entered into the database earlier this week.

Thanks,

Karen

Hi,
We are missing a few SUPPORT Primary outcomes. Please get these entered ASAP as we want to lock the database.

Thanks for all the effort!!
Rose

Subject: RE: Updates of tables 1-3

Marie wanted me to run the adjusted analyses while she was away, and I took my own time getting to it! I also used a different modeling approach that I have not had the chance to discuss with Marie yet; so please consider these draft results (and also the explanation for why some of the p values differ slightly from what you heard during our meeting in Rockville).

In doing adjusted analyses, my goal was to do this in a way that accomplishes two objectives:

1. Produce adjusted relative risks (and associated confidence intervals) instead of adjusted odds ratios, since the former make more sense interpreting in the context of a clinical trial.
2. Adjust for center, a stratification variable, as a traditional fixed effect (which means that we allow each center to have a different mean prevalence rate for the outcome), instead of treating it as a random effect (which indirectly adjusts for center effects by allowing babies from the same center to have outcomes more similar than those for babies across different centers).

After some experimentation, I settled on a generalized estimating equation (GEE) model that uses robust Poisson regression to produce adjusted relative risks, with center treated as a traditional fixed effect. In order to make this modeling approach computationally feasible, for most analyses I had to combine the data from 2 centers with less than 10 babies each, with their nearest larger center (Wake Forest was combined with Duke and Rochester with Yale). For the outcome of death by 36 weeks, I also had to combine Miami (<20 babies) with Emory.

The results, both for the design adjusted models (adjusting for GA strata, center and familial clustering) and for design + gender adjusted models, appear in the attached.

Please let me know if you have any questions.

Thanks

Abhik

Hi all,

Thanks for your patience while I was away. I have made few edits and comments to the latest version of Wally's paper. Wally, you had mentioned that you were missing some outcomes (like IVH/death) and I believe those were included in tables I sent on Sept. 3 (T2S Major Outcomes - PRELIMINARY 03SEP09.doc) – let me know if you need me to resend them.

Regarding the earlier question about the numbers in figure 1 differing from the monthly report, in the monthly report "*Eligible GDB patients are those keyed in the NG02 (inborn and GA of 24 0/6 & 27 6/7) with a birth date after the first Support patient keyed for sites at each Center and not born on or between dates of Support study suspension 11/23/2005 and 2/5/2006*" while the 3546 in figure 1 are those infants who were entered on the SUPP01 screening log. I'm not sure what to do about the difference unless we add them to the number who were "eligible but consent not sought." We should also be clear in figure 1 that many more moms were screened than are reflected on the SUPP01, because only those infants who were eventually assigned a GDB number (or who were enrolled in SUPPORT) were entered into the DMS. We could reference Wade's antenatal consent paper for a more accurate estimate of how many moms were screened.

FYI, while I was gone, queries went out to the centers regarding data that differed across GDB and SUPPORT forms and that will impact the secondary outcomes (including things like IVH) to some (hopefully small) degree. We have heard back from 10 centers so far, and I will review the results of the queries as we get responses to make sure all the necessary data are cleaned. I will also re-review the BPD outcome data to see if those queries have been completely cleared up yet and I will remind centers of any outstanding queries.

Thanks,
Marie

Subject: Oxygen saturation targeting paper

Dear Neil, Rose, Abhik, and Marie:

I have made several changes including:
1. Making Neil's suggestions
2. Improved Figure 2
3. Included Figure 1
4. Multiple minor changes.

I have made changes in all the numbers of the results as Abhik said they are still not final.

Enclosed is a clean draft so you can see my comments. I think we need to consider adding the ROP data if it is final before the paper is ready for submission.

I would appreciate any comments.

Thanks
Wally

ABSTRACT

Background

Non randomized studies suggest that the incidence of retinopathy decreases in premature infants with exposure oxygenation levels lower than previously maintained. However, the range of oxygen saturations that reduces retinopathy without increasing adverse outcomes is not known.

Methods

1316 infants of 24 to 27 weeks gestation born at 20 centers of the NICHD Neonatal Research Network (NRN) were randomly assigned at birth to oxygen saturation targets of 85 to 89% or 91 to 95%. The primary outcome was a composite of threshold retinopathy of prematurity, eye surgery for retinopathy, and/or death.

Results

Conclusions

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

INTRODUCTION

Comment [AD1]: Since we are not reporting ROP outcomes and would emphasize morality differences, I think we need to set the stage for doing that in the Intro itself, along the lines suggested in Neil's email dated 9/1/09.

Retinopathy of prematurity remains an important cause of blindness and other visual disabilities in prematurely born infants. The incidence of retinopathy of prematurity increased with exposure to unrestricted oxygen in premature infants in randomized controlled trials performed in the 1950s.[1] However, in subsequent years, the practice of restricting oxygen supplementation was estimated to result in an excess of 16 deaths per case of blindness prevented.[2] More recent data suggest that oxygen saturation levels previously thought to be in the upper limits of normal appear to also increase the risk of retinopathy of prematurity.[3-5] Oxygen toxicity may also increase the risk of mortality[6, 7], bronchopulmonary dysplasia[8-10], periventricular leukomalacia[11], cerebral palsy[12], and other morbidities. Although a multicenter study [13] could not determine an association between oxygen levels and retinopathy, a single center cohort study using transcutaneous oxygen monitoring supported the association of retinopathy with exposure to arterial oxygen levels $\geq$ 80mmHg.[14]

The recent introduction of pulse oximeters into the neonatal intensive care units, have allowed clinicians to utilize oxygen saturations to target oxygenation in premature infants. A survey study of 144 neonatal intensive care units conducted in 2001, revealed that the average lower limit of target oxygen saturations was 90% and the upper limit was 96%.[5] In recent years, the use of high saturation targets has been associated with the increased risk for retinopathy. The rate of retinal ablation surgery was higher at neonatal intensive care units with maximal target oxygen saturation $\geq$ 98% (5.6 $\pm$ 1.1 versus 3.1 $\pm$ 0.3%) or $\geq$ 92% (3.3 $\pm$ 0.3 versus 1.4 $\pm$ 0.2%).[5] Recent studies suggest that oxygen saturation targeting from the first day after birth at levels lower than previously used may reduce the incidence of retinopathy. In a retrospective study comparing outcomes at five neonatal intensive care units, the incidence of severe

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

retinopathy requiring ablation therapy was 27% in units where target saturations were 88 to 98% and only 6% in units where the target was 70 to 90%.[3] Rates of mortality and cerebral palsy did not differ in these units. In three other studies, a policy of oxygen saturation targeting of approximately 83 to 95% resulted in a substantial reduction in retinopathy.[4, 15, 16] However, in these studies, actual oxygen saturations achieved were not reported. Pulse oximetry has become the standard technique for continuous monitoring of oxygenation. While data from recent prospective observational and retrospective studies[3, 4, 15-19] suggest that maintenance of oxygenation at ranges lower than previously used may decrease the incidence of retinopathy of prematurity, there is no conclusive evidence that these oxygenation levels do so without an increase in serious adverse effects.

We conducted a 2 x 2 factorial-design multicenter randomized trial of oxygen saturation targeting and ventilation strategy. ~~: testing~~ The oxygen saturation arm tested the effect of a lower oxygen saturation target range (85-89%) ~~as~~ compared to a higher oxygen saturation target range (91-95%) on the incidence of threshold retinopathy of prematurity, eye surgery for retinopathy, and/or death among infants of 24 to 27 weeks gestational age at birth. ~~The factorial design allowed comparison~~The ventilation arm of this factorial design trial also allowed us to simultaneously test~~ed~~ the effect of ~~of~~ prophylactic/early surfactant versus continuous positive airway pressure~~: thus, controlling for the approach to ventilatory support~~ on bronchopulmonary dysplasia or death at 36 weeks postmenstrual age (results published elsewhere). Note that the factorial nature of the trial design effectively controlled for ventilator approaches in the oxygen saturation arm of this trial, which is the subject of this report.

METHODS

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

The institutional review boards at all Neonatal Research Network clinical centers and at Research Triangle International (data center) approved the trial. Written informed consent was obtained from the parent or guardian of each participant before delivery.

Patients

Infants of $24^{0/7}$ to $27^{6/7}$ weeks gestational age, without a decision to forgo support were eligible for enrollment at birth. Exclusion criteria were outborn infants and major congenital anomalies. Multiple births were randomized to the same arm of the trial.

Enrollment and treatment

~~Infants~~ Deliveries were stratified by center and by gestational age ($24^{0/7}$ to $25^{6/7}$ weeks or $26^{0/7}$ to $27^{6/7}$ weeks). ~~Infants~~ They were randomly assigned by means of double-sealed envelopes to oxygen saturation targeting of 85 to 89% or 91 to 95%. Masking was maintained using electronically-altered pulse oximeters with output display of 88 to 92% for these oxygen ranges, with an offset of 3% as previously used to separate oxygen saturations in premature infants.[20] ~~Participants were also randomly assigned to respiratory support using either prophylactic/early surfactant with conventional ventilation management or to continuous positive airway pressure with a permissive ventilatory strategy.~~ The oxygen saturation values displayed reverted to actual values when less than 84~~5~~% or greater than 96~~5~~%. Oxygen saturation targeting with the altered pulse oximetry was initiated within the first two hours after birth and was continued until 36 weeks post-menstrual age or until the infant remained on room air and off the ventilator/continuous positive airway pressure for more than 72 hours. Infants weaned to room air but who subsequently received oxygen supplementation before 36 weeks post-menstrual age were placed back on the assigned study pulse oximetry. Adjustments in supplemental oxygen to target

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

oxygen saturations were performed by the clinicians, not by the research staff. For the ventilation arm of this 2 by 2 factorial design trial (results reported elsewhere), participants were also randomly assigned to respiratory support using either prophylactic/early surfactant with conventional ventilation management or to continuous positive airway pressure with a permissive ventilatory strategy.

Assessments

Research nurses recorded all data using standardized definitions. Data were collected until discharge or 120 days postnatal age whichever occurred first. Threshold retinopathy of prematurity (New Type 1 threshold per Early Treatment of Retinopathy [ETROP] Cooperative Group[21]) was coded if any of the following four findings were present up to 55 weeks post-menstrual age:

If in zone 1: Stage 3 retinopathy of prematurity, even without plus disease

Plus disease with any stage retinopathy of prematurity

If in zone II: Plus disease with stage 2 retinopathy of prematurity

Plus disease with stage 3 retinopathy of prematurity

Surgical intervention included laser therapy, cryotherapy, laser/cryotherapy, scleral buckle, and vitrectomy. Outcomes included predefined clinical diagnoses and potential adverse events.

Comment [MG2]: We are also including treatment with Avastin, correct?

Statistical analysis

The primary analysis for the oxygen saturation arm of this factorial trial was a ~~logistic regression~~ generalized estimating equation (GEE) model that used robust Poisson regression to produce adjusted relative risks comparing ~~analysis of the percentages of~~incidence rates for infants in each treatment group (lower versus higher oxygen saturations) who developed the primary outcome. The model

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

produces relative risk estimates adjusted for stratification by center and gestational age, and for the familial clustering induced by randomization of multiple births to the same treatment.

An absolute difference of 10% between the two treatment groups was considered clinically important. To detect this difference, we planned to enroll ~~1312~~ 1310 infants for 80% power to detect a 10% difference in outcome assuming ~~and~~ a baseline estimated rate of ~~45~~50% of death/threshold retinopathy/surgery. This sample size estimate included ~~, based on~~ an increase by a factor of 1.12 to account for randomizing multiples to the same treatment group and on an increase by a factor of 1.17 to account for the expected attrition after discharge and before follow up. While these sample size calculations allowed for the testing of two co-primary outcomes for the two intervention arms (oxygenation and ventilation) of this 2 by 2 factorial trial, t~~T~~he trial was not powered to determine an interaction between the two interventions. Intention-to-treat analyses were performed. The denominator used to calculate the rate of each outcome was the number of infants for whom that outcome was known. All analyses were conducted ~~by~~ at RTI International, the independent ~~d~~Data Coordinating ~~c~~Center for the NRN. A two-sided P value of less than 0.05 was considered to be statistically significant. Analyses did not include adjustment for multiple comparisons. An independent data safety and monitoring committee appointed by the Director of the NICHD reviewed the primary outcomes, adverse events, and other interim results at ~**25%, 50%, and 75%** of planned enrollment. Lan-DeMets spending functions with Pocock (O'Brien-Fleming) boundaries were used to develop stopping rules for interim safety (efficacy) monitoring. Safety outcomes monitored included death, …, and a combination of any of the above events.

Comment [MG3]: This is what is listed on clinicaltrials.gov

Comment [MG4]: The final DSMC review will take place on November 4 to review 100% of the BPD/death data and as much of the ROP data as we have at that time.

RESULTS

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

1316 infants were enrolled between January 2004 and March 2009 (Figure 1). Enrollment was temporarily stopped by the Data Safety and Monitoring Committee (DSMC) because of concerns regarding compliance with oxygen saturation targets. Separate of analysis of the oximetry data while on room air versus while on oxygen supplementation resolved the concerns, and trial enrollment resumed upon DSMC approval. The baseline characteristics of the lower saturation group and the higher saturation group were similar (Table 1).

Major outcomes

The Data Safety and Monitoring Committee masked interim analyses for safety were made available to the investigators after enrollment was completed. There had been a trend for increased mortality in one of the treatment groups that had not reached the stopping boundary. The principal investigator and ~~data center~~DCC staff then undertook a more detailed safety analysis to evaluate potential adverse outcomes without unblinding the retinopathy outcome data. This manuscript reports the hospital outcomes. Retinopathy and 18-22 month follow up outcomes will be reported later.

Mortality at any time during hospitalization occurred in 130 of the 655 (20%) of the infants in the lower oxygen saturation group versus in 106 of the 661 (16%) of the infants in the higher oxygen saturation group (adjusted RR 0.78, CI 0.62, 0.99, P=0.04). Comparable results were observed within both gestational age groups used for stratification. Mortality in the first and second weeks after birth was comparable in the two treatment groups (Table 2). Other prespecified major outcomes were comparable between the two treatment groups (Table 2).

Comment [AD5]: Is it just enrollment, or when all babies had reached status, as defined in the GDB (death, discharge, transfer or 120 days of age) ? Will we get into trouble for sharing such data with the investigators before all primary outcomes were available?

Comment [AD6]: I think we can make this stronger – the data is not all available and the investigators have not even seen the available data by group – correct?

Comment [AD7]: In order for NEJM to consider this, I think the rationale needs to be strengthened here along the following lines:
We performed a detailed safety analysis which uncovered clinically and statistically significant trends with respect to mortality. While acknowledging that the designated primary outcome for this trial is death or ROP, since death is the ultimate safety outcome, we decided not to wait for incoming ROP outcome data (which will take substantially more time to collect and QC) and report the mortality findings to the practicing neonatal community while the ROP data accumulates.

Comment [AD8]: Are we also reporting gender adjusted results?

The median oxygen saturation of both groups differed substantially but, as expected, there was some overlap (Figure 2). These data indicate that actual oxygen saturation levels are slightly higher than targets in both treatment groups. The duration of oxygen supplementation was shorter in the lower oxygen saturation group but the duration of mechanical ventilation, continuous positive airway pressure, and nasal synchronized intermittent mandatory ventilation did not differ (Table 3). Other measures of resource utilization did not differ as well.

DISCUSSION

The recommended ranges of oxygen saturation targeting for very preterm infants have been determined from nonrandomized studies and restriction of oxygen supplementation is becoming the standard practice.[3, 22] However, there was an increase in mortality when a restrictive oxygen supplementation was practiced in the 1950s and 1960s. Despite notw being based on randomized controlled trials and limited evidence of safety, lower oxygen saturation targeting has become been the recommendedincreasingly adopted by units and physicians who are desirous of decreasing significant retinopathy of prematurity. In the current trial, we however observed that lower oxygen saturation targeting (85-89%) resulted in an increased risk of mortality.

This trial was not prospectively powered for a difference in mortality only between the two oxygen saturation groups and, thus, the results should be viewed with caution. However, this is the largest completed prospective multi-center randomized trial to test the effect of lower versus higher oxygen saturation targeting and the results add to previous data raising the concern that oxygen restriction may increase mortality in very preterm infants. The infants in this trial were more immature than those of

Comment [MG9]: Although death was not the pre-specified primary outcome, the fact that the study was not specifically powered to detect a difference in death rate should not in itself lead us to be cautious about the findings. Recall that the study was powered conservatively for an outcome rate of 50%. It turned out that we also had the power to detect a difference in death rates of 16% vs. 20%.

any previous trials of oxygen restriction and, thus, may have had a higher susceptibility to the effects of lower oxygen saturation targeting. In addition, aside from the decreased use of oxygen supplementation at 36 weeks, there were no other benefits from oxygen restriction among the outcomes reported in this paper. The previous data on the increased mortality from oxygen restriction were from studies with lower levels of evidence compared to randomized controlled trials. It is interesting and worrisome that the combined risk difference observed in the 1950s was a 4.9% increase in mortality in the oxygen restricted group, which is very similar to the 4% mortality increase in the lower targeted SpO2 group that was observed in our trial. (Ref 1).

Restriction of oxygenation in previous randomized controlled trials in preterm infants beyond the first weeks of life did not show trends for increased mortality in the lower saturation target groups.[17, 18] However, these trials aimed for saturations of 91 to 94% and 89 to 94% in the lower oxygen saturation group. Mortality in the current trial did not differ by 7 or 14 days. Therefore, we surmise that the lower target of oxygen saturations rather than the postnatal age of the intervention is related to the adverse outcome.

There are several ongoing trials across the world that address the same intervention tested in the current trial as well as a planned prospective meta-analysis.[1] At the present time, it is important that these trials continue. and it will be important that the investigators and the data safety and monitoring committees of these trials are aware of the results of the current trial so appropriate decisions can be made regarding their interim analyses, completion of the trials, and dissemination of the data. The current trial raises the concern of adverse hospital outcomes due to oxygen saturation targeting in the 85

to 89% range. Further information from the ongoing randomized controlled trials that evaluate lower versus higher oxygen saturation targeting will become available in the next years but at the present time, caution should be exercised regarding oxygen targeting in the low range for extremely premature babies such as those tested in the current trial.

CENTER: 19 NETWORK: (b) (6) SITENM: (b) Mother's Initials: *** , Birth No: 1

This form should be completed for all inborn infants with a gestational age of 24 0/7 to 27 6/7 weeks gestation by best obstetrical estimates and who are to receive full resuscitation.

A. INCLUSION CRITERIA

1. Inborn infant with a minimal gestational age of 24 weeks 0 days to 27 6/7 completed weeks by best obstetrical estimate? **Y**
2. Infant to receive full resuscitation as necessary? **Y**
3. Infant does not have known major congenital malformations? **Y**

If any of above questions are answered 'N' infant is NOT eligible.

B. EXCLUSION CRITERIA

1. The infant was born during a time when the research apparatus/study personnel are not available? **N**

   If Yes, indicate reason:

   1 = Equipment not available 2 = Personnel not available

C. CONSENT

1. Consent Status: **1**

   0 = Not eligible
   1 = Consent granted
   2 = Parent unavailable
   3 = Parent refused consent
   4 = Consent not requested
   5 = Physician refused consent

   a. If parent refused consent (3), consent not requested (4) or physician refused consent (5), indicate reason:

D. RANDOMIZATION

1. Was infant randomized into the study? **Y**

   If No, indicate reason(s):

   If Yes,

   a. Date: (b) (6)
   Month Day Year

   b. Time: **14:05**
   Hour Min

   c. Randomization Number (b) (6)

   d. Treatment Assignment **2**

   1= Early Extubation and CPAP 2= Early Surfactant and Ventilation

   e. Oximeter Color Code: **1**

   1= Blue 2= Orange

Initials of person completing this form: **KRF**

SUPP02 Form Completion Date: **08/30/2005**

If Yes,

1. Number of doses:

9. Status following resusciation: **1**

1 = Admitted to NICU for further care
2 = Infant Died

Initials of person completing this form: **KRF**

SUPP03 Form Completion Date: **01/18/2006**

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

CENTER: 19 NETWORK: (b) (6) SITENM: [redacted] Mother's Initials: *** , Birth No: 1

A. NICU ADMISSION

1. Date and time of NICU admission

   a. Date: (b) (6) (Month Day Year) b. Time: 14:30 (Hour Min)

2. Respiratory Support on admission to the NICU: 2

   1 = HVF 2 = CV 3 = Nasal SIMV 4 = CPAP 5 = NC 6 = Hood 7 = No Support

3. SaO2: 091

4. FiO2: 0.30

5. Was blood gas done after admission to the NICU? Y

   If Yes, record the first blood gas after admission:

   a. Date: (b) (6) (Month Day Year) b. Time: 15:15 (Hour Min)

   c. Source: 1

      1= Arterial 2= Venous 3= Capillary

   d. pH: 7.30

   e. pCO2: 047

   f. pO2: 107

   g. FiO2: 0.21

6. Date and time the study oximeter was placed on this infant.

   a. Date: (b) (6) (Month Day Year) b. Time: 14:10 (Hour Min)

   c. Serial number: 316774

B. NICU PROCEDURES

1. Was infant intubated for the first time within the first 14 days after admission to the NICU? N

   If Yes,

   a. Date: (Month Day Year) b. Time: (Hour Min)

   c. Indication for intubation:

      1. Surfactant?
      2. FiO2 > .50 to maintain SaO2 >= 88%
      3. pCO2 > 65 on single blood gas?
      4. Apnea requiring bag and mask ventilation?
      5. If NO to all above, state reason:

         1= Hemodynamic instability 2 = Clinical shock/sepsis 3 = Other

         If Other (3), specify

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

COMPLETE SECTION A IF THE INFANT IS INTUBATED/CPAP FOR > 8 HOURS ON THIS DAY (RECORD THE GAS CLOSEST TO THE SCHEDULED TIMES).

B. SUPPLEMENTAL OXYGEN INFORMATION:

a. Scheduled Time	b. Time Measured (hour : min)	c. FiO2	d. Flow Rate	e.** Mode of O2 Delivery
1. 12:00 (Noon)				

** 5 = Cannula 6 = Hood

C. INTUBATED/EXTUBATED INFORMATION: (FOR NICU ONLY) If more than one intubation/extubation occurs in one day, complete the SUPP05A Form

1. Was the Infant intubated on this day? N
   a. If Yes, Record the time of intubation
   b. Record the following prior to intubation: (hh:mm)
      1. pH
      2. PCO2
      3. FiO2
      4. Saturation
      5. Apnea?
      6. Sepsis/R/O Sepsis?
      7. Hemodynamic instability?
      8. Clinically significant PDA?
      9. Other
         (specify)?

CENTER: 19 NETWORK: (b) (6) SITENM: (b) Mother's Initials: *** , Birth No: 1

A. MATERNAL INFORMATION

1. Mother's age (years): **21**
2. Maternal Zip Code: (b) (6)
3. Pregnancy history (include this pregnancy):
   a. Gravida: **08**
   b. Parity: **03**
4. Marital Status: **1**

   1 = Married 2 = Single 6 = Unknown

5. Highest level of education achieved by the Biological Mother: **3**

   1 = < 7th grade
   2 = 7th to 9th grade
   3 = 10th to 12th grade
   4 = High School degree
   5 = Partial college
   6 = College degree
   7 = Graduate degree
   8 = Unknown

6. Mother's medical insurance: **1**

   1 = Medicaid
   2 = Medicaid HMO
   3 = Private
   4 = Other HMO
   5 = Self-pay
   6 = Unknown
   7 = Both private public (e.g. Medicaid; CHIPS) assistance
   8 = No insurance upon admission

B. PREGNANCY COMPLICATION

1. Multiple birth? **N**
   a. If YES, Number of fetuses:
2. Mother had at least one pre-natal care visit for this pregnancy? **Y**
3. Was this pregnancy the product of artificial reproductive technology? **N**
4. Diabetes - insulin dependent? **N**
5. Hypertension/pre-eclampsia/eclampsia? **Y**
6. Antepartum hemorrhage? **N**

C. LABOR AND DELIVERY

1. Rupture of membranes:
   a. Date: (b) (6) (Month Day Year) b. Time: **08:00** (Hour Min)
2. Was there labor? **N**

   If YES, onset of labor:

   a. Date: (Month Day Year) b. Time: (Hour Min)
3. Were steroids given prior to delivery to accelerate maturity? **Y**
   a. If YES, Type of antenatal steroid given: **1**

   1 = Betamethasone 2 = Dexamethasone 3 = Both

   b. Was a complete course given within 7 days prior to delivery? **Y**
   c. Total number of courses given during this pregnancy: **01**
4. Were tocolytics used during the admission resulting in this delivery? **Y**
5. Were antibiotics used during the admission resulting in this delivery? **Y**
6. Final mode of delivery: **3**

   1 = Vaginal vertex 2 = Vaginal breech 3 = Cesarean section

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

CENTER: 19 NETWORK: (b) (6) SITENM: [redacted] Mother's Initials: *** , Birth No: 1

D. NEONATAL INFORMATION

1. Date and time of birth:

   a. Date: (b) (6) (Month Day Year) b. Time: **14:07** (Hour Min)

2. Was the infant outborn? **N**

   If YES, date and time admitted to NICU:

   a. Date: (Month Day Year) b. Time: (Hour Min)

3. Did the infant die <= 12 hours? **N**

   IF YES, COMPLETE FORM NG03E

4. Sex: **1**

   1 = Male 2 = Female 3 = Ambiguous

5. Race: **1**

   1 = Black, not Hispanic
   2 = White, not Hispanic
   3 = Hispanic, White
   4 = Hispanic, Black
   5 = American Indian or Alaska Native
   6 = Asian or Pacific Islander
   7 = Other

6. Gestational age:

   a. Weeks: **24** b. Days: **2**

7. Apgar score - 1 minute: **01**
8. Apgar score - 5 minutes: **07**
9. Delivery room resuscitation:
   - a. Oxygen? **Y**
   - b. Bagging and mask? **Y**
   - c. Chest compression? **N**
   - d. Intubation? **Y**
   - e. Drugs? **N**
10. Birth Weight: (grams): **0700**
11. Length (cm): **30.0**
12. Head Circumference (cm): **22.0**
13. Was cord blood gas done? **N**

    If Yes,

    a. Cord arterial pH (if done):
    b. Cord venous pH (if done):
    c. Cord pH (unknown vessel):
    d. Arterial base deficit (if done):
    e. Venous base deficit (if done):
    f. Base deficit (unknown vessel):

A. STATUS

1. Status of infant at time of completion of form: 1

```
1 = Discharged to home                    4 = Transferred to chronic care facility
2 = Still in hospital at 120 days         5 = Death
3 = Transferred to another hospital
```

2. Date of status: (b) (6) (Month Day Year)
3. Weight at status (grams): 1995
4. Length at status (cm): 38.0
5. Head circumference at status (cm): 32.0
6. Was respiratory support withheld and/or withdrawn at any time between birth and 24 hours after the infant was born? N

B. PULMONARY

1. Respiratory distress:
   a. Required oxygen at 6 hours of life continuing to age 24 hours? Y
   b. Demonstrated clinical features of respiratory distress within age 24 hrs? Y
   c. Had need for respiratory support to age 24 hours? Y
   d. Had an abnormal chest x-ray within age 24 hours? Y
2. Did the baby receive surfactants? Y
   a. If YES, total number of surfactant doses: 002
3. Pneumothorax? N
4. Pulmonary hemorrhage? N
5. Chest x-ray done after 21 days of age? Y

   If YES,

   a. Was x-ray consistent with BPD? Y
   b. If YES, date of x-ray after day 21 and closest to day 28 used to meet criteria: (b) (6) (Month Day Year)
6. Did baby require supplemental O2 at 36 weeks? Y
7. Was chest x-ray done at 36 weeks? Y

   If Yes,

a. Was x-ray consistent with BPD/CLD? N
   b. Date of x-ray at 36 weeks: (b) (6) (Month Day Year)
8. Steroids for BPD/CLD? N
   a. If YES, Date of first dose: (Month Day Year)
9. Conventional ventilator? Y
10. High frequency ventilator? N

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

CENTER: 19 NETWORK: (b) (6) SITENM: [redacted] Mother's Initials: *** , Birth No: 1

C. CARDIAC

1. Patent ductus arteriosus (PDA)? Y
   If YES,
   a. Indomethacin for PDA? Y
   b. Surgery for PDA? N

D. NEUROLOGIC

1. Was indomethacin given within the first 24 hrs for any indication? N
   If YES,
   a. Date: [redacted] (Month Day Year) b. Time: [redacted] (Hour Min)
2. Seizures? N
   a. If YES, Confirmed by EEG? [redacted]
3. Were any cranial sonograms done within 28 days of birth? Y
   If NO, Go to Question D6
   a. If Yes, Were all studies Normal? Y
   If Yes, Go to Question D6
   b. Date of sonogram for most severe hemorrhage: [redacted]
   Month Day Year
   c. Blood/echodensity in germinal matrix/subependymal area? [redacted]
   d. Blood/echodensity in the ventricle? [redacted]
   e. Blood/echodensity in the parenchyma? [redacted]
   f. Ventricular size enlarged? [redacted]
4. Cystic area(s) in the parenchyma within 28 days? [redacted]
5. Periventricular leukomalacia within 28 days? [redacted]
6. Were any cranial sonograms done after 28 days of birth? Y

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

7. Cranial sonogram closest to 36 weeks postconceptional age:
   a. Date of sonogram: (b) (6) Month Day Year
   b. Normal study? Y
      If YES, Go to Question 8
   c. Ventricular size enlarged?
   d. Cystic area(s) in the parenchyma?
   e. Cystic periventricular leukomalacia?
   f. Porencephalic cyst?
8. Surgical placement of a shunt for post hemorrhagic hydrocephalus/ persistent ventriculomegaly? N

E. INFECTION

1. Intra-uterine infection? N
   If YES, organism code(s): a. b.
2. Early onset septicemia/bacteremia at (<= 72 hours)? N
   If YES, organism code(s): a. b.
3. Did the infant receive antibiotics for >= 5 days, starting within the first 72 hours? Y
4. Number of episodes of late onset culture negative clinical infection (>=72 hours to status) treated with antibiotics for >= 5 days: 02
5. Late onset culture positive septicemia/bacteremia (>= 72 hours)? Y

   If YES,

   a. Number of episodes between day 3 and status that were treated with antibiotics for >= 5 days: 02
   b. Organism code(s) and date of first positive culture for each of episodes for which the infant was treated with antibiotics for >= 5 days:

a)Episode#	(b) Date	(1) Organism	(2) Organism	(3) Organism
1	(b) (6)	104		
2	(b) (6)	230		
3				
4				
5				
6				

6. Infection of meninges/brain? N
   a. If YES,

a)Episode#	(b) Date	(1) Organism	(2) Organism	(3) Organism
1				
2

F. GASTROINTESTINAL

1. Did the infant lose weight? Y
   a. If YES, Lowest weight? 0500
      1) Date of lowest weight: (b) (6) Month Day Year
   b. If YES, Did the infant regain birth weight? Y
      1) If YES, Date when first regained: **/**/**** Month Day Year
2. Did the baby receive patenteral alimentation? Y
   If YES,
   a. Date of first patenteral alimentation (b) (6) Month Day Year
   b. Parenteral alimentation, total number of days: 049
3. Did the baby receive enteral feeds? Y
   If YES,
   a. Date of first enteral feed: (b) (6) Month Day Year
   b. Were full enteral feeds achieved? Y
      1) If YES, date first achieved: (b) (6) Month Day Year
4. Proven NEC: 0

   0 = Absent/Suspect 2 = Proved, no surgery 3 = Proved, surgery

   a. If proven NEC, Date of first episode? Month Day Year
5. Spontaneous gastrointestinal perforation? N
   a. If YES, date of the first spontaneous gastrointestinal perforation: Month Day Year
6. Did the infant have GI surgery that resulted in short gut? N

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

CENTER: 19 NETWORK: (b) (6) SITENM: [redacted] Mother's Initials: *** Birth No: 1

G. HEARING

1. Was a Hearing screen performed? **Y**

   a. If YES, hearing screen protocol used: **2**

   1 = OAE 2 = AABR 3 = ABR 4 = OAE + AABR 5 = Other

   b. Final screen results before discharge

      i) Right ear: **1**

      ii) Left ear: **1**

      Results: 1. Pass 2. Fail 3. Incomplete

   c. If a failed screen in either ear, was a diagnostic ABR done prior to status?

      1) If YES, answer the following:

         i) Right ear:

         ii) Left ear:

         Results: 1. Pass 2. Fail 3. Incomplete

H. OPHTHALMOLOGY

1. Was an exam performed for ROP? **Y**

   a. If YES, was ROP diagnosed? **Y**

      1) If ROP diagnosed, record highest stage in lowest zone:

         i. Highest Stage:

	a) Right (OD)	b) Left (OS)
	2	**2**

         0 = No disease 2 = Stage II 4 = Stage IV
         1 = Stage I 3 = Stage III 5 = Stage V

         ii. Lowest Zone:

	a) Right (OD)	b) Left (OS)
	2	**2**

         1 = Zone I 2 = Zone II 3 = Zone III

         iii. Plus Disease?

	a) Right (OD)	b) Left (OS)
	N	**N**

      2) If ROP diagnosed, was threshold ROP diagnosed at any time?

         i. Right **Y**

         ii. Left **Y**

      3). Intervention Therapies:

         a. Was retinal ablation performed prior to a threshold diagnosis?

            i. Right: **N**

            ii. Left **N**

         b. Was any surgery performed? (Enter Code)

            i. Right: **0**

            ii. Left: **0**

            0 = None 1 = Lasertherapy 2 = Cryotherapy
            3 = Scleral buckle 4 = Other (specify)

            If Other(4) for Right eye, Specify

            If Other(4) for Left eye, Specify

K. 28 DAY ANTHROPOMETRICS

1. Status at 28 Days: 2

1 = Discharged 2 = In hospital 3 = Transferred 5 = Death

If "2", (In Hospital):

a. Date at 28 Days: (b) (6)
Month Day Year

b. Weight (g): 0632

c. Length (cm): 36.0

d. Head circumference (cm): 22.0

L. 36 WEEK INFORMATION

1. Status at 36 weeks: 2

1 = Discharged 2 = In hospital 3 = Transferred 5 = Death

If "2", (In Hospital):

a. Date of 36 weeks: (b) (6)
Month Day Year

b. Weight (g) 1361

c. Length (cm): 38.0

d. Head circumference (cm) 29.3

M. TRANSFER

Complete this section if status (AI) of infant at time of completion of this form is 3 or 4

1. Date of transfer:
Month Day Year

2. Transferred on oxygen?

3. Final outcome:

1 = Died in Hospital 2 = Discharged to Home 6 = In hospital at one year

a. If discharged to home, final weight at discharge (grams):

N. DISCHARGE ALIVE

Complete this section if status (Q.A1) of infant at time of completion of this form is "1" or if the final outcome for a transferred infant is "Discharged to home."

1. Date of discharge to home: (b) (6)
Month Day Year

2. Discharged home on oxygen? N

3. Discharged home on any of the following medications? Y

If YES,

a. Diuretics? Y

b. Bronchodilators? N

c. Anticonvulsants? N

d. Antireflux medications? Y

This form should be completed for all inborn infants with a gestational age of 24 0/7 to 27 6/7 weeks gestation by best obstetrical estimates and who are to receive full resuscitation.

A. INCLUSION CRITERIA

1. Inborn infant with a minimal gestational age of 24 weeks 0 days to 27 6/7 completed weeks by best obstetrical estimate? **Y**
2. Infant to receive full resuscitation as necessary? **Y**
3. Infant does not have known major congenital malformations? **Y**

If any of above questions are answered 'N' infant is NOT eligible.

B. EXCLUSION CRITERIA

1. The infant was born during a time when the research apparatus/study personnel are not available? **N**

   If Yes, indicate reason:

   1 = Equipment not available 2 = Personnel not available

C. CONSENT

1. Consent Status: **1**

   0 = Not eligible
   1 = Consent granted
   2 = Parent unavailable
   3 = Parent refused consent
   4 = Consent not requested
   5 = Physician refused consent

   a. If parent refused consent (3), consent not requested (4) or physician refused consent (5), indicate reason:

D. RANDOMIZATION

1. Was infant randomized into the study? **Y**

   If No, indicate reason(s):

   If Yes,

   a. Date: (b) (6)
   Month Day Year

   b. Time: **23:53**
   Hour Min

   c. Randomization Number (b) (6)

   d. Treatment Assignment **1**

   1= Early Extubation and CPAP 2= Early Surfactant and Ventilation

   e. Oximeter Color Code: **2**

   1= Blue 2= Orange

Initials of person completing this form: **KJA**

SUPP02 Form Completion Date: **11/15/2005**

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

a. Scheduled Time	b. Time Measured (hour : min)	c. FiO2	d. Flow Rate	e.** Mode of O2 Delivery
1. 12:00 (Noon)				

** 5 = Cannula 6 = Hood

C. INTUBATED/EXTUBATED INFORMATION: (FOR NICU ONLY) If more than one intubation/extubation occurs in one day, complete the SUPP05A Form

1. Was the Infant intubated on this day? N
   a. If Yes, Record the time of intubation
   b. Record the following prior to intubation: (hh:mm)
      1. pH
      2. PCO2
      3. FiO2
      4. Saturation
      5. Apnea?
      6. Sepsis/R/O Sepsis?
      7. Hemodynamic instability?
      8. Clinically significant PDA?
      9. Other
         (specify)?

A. STATUS

1. Status of infant at time of completion of form: 3

```
1 = Discharged to home                    4 = Transferred to chronic care facility
2 = Still in hospital at 120 days         5 = Death
3 = Transferred to another hospital
```

2. Date of status: (b) (6)
   Month Day Year
3. Weight at status (grams): 1355
4. Length at status (cm): 39.4
5. Head circumference at status (cm): 26.5
6. Was respiratory support withheld and/or withdrawn at any time between birth and 24 hours after the infant was born? N

B. PULMONARY

1. Respiratory distress:
   a. Required oxygen at 6 hours of life continuing to age 24 hours? Y
   b. Demonstrated clinical features of respiratory distress within age 24 hrs? Y
   c. Had need for respiratory support to age 24 hours? Y
   d. Had an abnormal chest x-ray within age 24 hours? Y
2. Did the baby receive surfactants? N
   a. If YES, total number of surfactant doses:
3. Pneumothorax? N
4. Pulmonary hemorrhage? N
5. Chest x-ray done after 21 days of age? Y

   If YES,

   a. Was x-ray consistent with BPD? Y
   b. If YES, date of x-ray after day 21 and closest to day 28 used to meet criteria: (b) (6)
      Month Day Year
6. Did baby require supplemental O2 at 36 weeks? N
7. Was chest x-ray done at 36 weeks? N

   If Yes,

   a. Was x-ray consistent with BPD/CLD?
   b. Date of x-ray at 36 weeks:
      Month Day Year
8. Steroids for BPD/CLD? N
   a. If YES, Date of first dose:
      Month Day Year
9. Conventional ventilator? Y
10. High frequency ventilator? N

C. CARDIAC

1. Patent ductus arteriosus (PDA)? N

If YES,

a. Indomethacin for PDA?

b. Surgery for PDA?

D. NEUROLOGIC

1. Was indomethacin given within the first 24 hrs for any indication? Y

If YES,

a. Date: (b) (6) (Month Day Year) b. Time: 03:00 (Hour Min)

2. Seizures? N

a. If YES, Confirmed by EEG?

3. Were any cranial sonograms done within 28 days of birth? Y

If NO, Go to Question D6

a. If Yes, Were all studies Normal? Y

If Yes, Go to Question D6

b. Date of sonogram for most severe hemorrhage:

Month Day Year

c. Blood/echodensity in germinal matrix/subependymal area?

d. Blood/echodensity in the ventricle?

e. Blood/echodensity in the parenchyma?

f. Ventricular size enlarged?

4. Cystic area(s) in the parenchyma within 28 days?

5. Periventricular leukomalacia within 28 days?

6. Were any cranial sonograms done after 28 days of birth? Y

This form should be completed for all inborn infants with a gestational age of 24 0/7 to 27 6/7 weeks gestation by best obstetrical estimates and who are to receive full resuscitation.

A. INCLUSION CRITERIA

1. Inborn infant with a minimal gestational age of 24 weeks 0 days to 27 6/7 completed weeks by best obstetrical estimate? **Y**
2. Infant to receive full resuscitation as necessary? **Y**
3. Infant does not have known major congenital malformations? **Y**

If any of above questions are answered 'N' infant is NOT eligible.

B. EXCLUSION CRITERIA

1. The infant was born during a time when the research apparatus/study personnel are not available? **N**

   If Yes, indicate reason:

   1 = Equipment not available 2 = Personnel not available

C. CONSENT

1. Consent Status: **1**

   0 = Not eligible
   1 = Consent granted
   2 = Parent unavailable
   3 = Parent refused consent
   4 = Consent not requested
   5 = Physician refused consent

   a. If parent refused consent (3), consent not requested (4) or physician refused consent (5), indicate reason:

D. RANDOMIZATION

1. Was infant randomized into the study? **Y**

   If No, indicate reason(s):

   If Yes,

   a. Date: (b) (6)
   Month Day Year

   b. Time: **11:30**
   Hour Min

   c. Randomization Number (b) (6)

   d. Treatment Assignment **1**

   1= Early Extubation and CPAP 2= Early Surfactant and Ventilation

   e. Oximeter Color Code: **2**

CENTER: 19 NETWORK: (b) (6) SITENM (b) (6) Mother's Initials: *** , Birth No: 1

A. MATERNAL INFORMATION

1. Mother's age (years): 34
2. Maternal Zip Code: (b) (6)
3. Pregnancy history (include this pregnancy):
   a. Gravida: 04
   b. Parity: 02
4. Marital Status: 2

1 = Married	2 = Single	6 = Unknown

5. Highest level of education achieved by the Biological Mother: 4

1 = < 7th grade	5 = Partial college
2 = 7th to 9th grade	6 = College degree
3 = 10th to 12th grade	7 = Graduate degree
4 = High School degree	8 = Unknown

6. Mother's medical insurance: 1

1 = Medicaid	6 = Unknown
3 = Private	9 = Other
5 = Self-pay/uninsured	

B. PREGNANCY COMPLICATIONS

1. Multiple birth? N
   a. If YES, Number of fetuses:
2. Mother has evidence of at least one prenatal visit in this pregnancy? Y
3. Diabetes - insulin dependent? N
   If YES, was insulin given prior to pregnancy?
4. Hypertension? N
   a. Hypertension existed prior to pregnancy?
5. Antepartum hemorrhage? N
6. Was Chorioamnionitis documented in the mother's medical record? N
7. Was a placental pathology performed? Y
   If YES,
   a. Was histologic chorioamnionitis documented? Y

C. LABOR AND DELIVERY

1. Was there a rupture of membranes prior to delivery? U
   If Yes,
   a. Date: Month Day Year
   b. Time: Hour Min
   c. If date and/or time unknown, were ROM estimated at > 18 hours?
2. Were steroids given prior to delivery to accelerate maturity? Y
   a. If YES, Type of antenatal steroid given: 1

1 = Betamethasone	2 = Dexamethasone	3 = Both	4 = UK

   b. Was a complete course of steriods given prior to delivery? N

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

3. Were maternal antibiotics used during the admission resulting in this delivery? Y

   a. If YES, were antibiotics given within 72 hrs prior to delivery? Y

   1. 01 3. 5.

   2. 4. 6.

4. Final mode of delivery: 1

1 = Vaginal vertex	2 = Vaginal breech	3 = Cesarean section	4 = Vaginal NOS	5 = Unknown

D. NEONATAL INFORMATION

1. Date and time of birth:

   a. Date: (b) (6) (Month Day Year) b. Time: 11:50 (Hour Min)

2. Was the infant outborn? N

   If YES, date and time admitted to NICU:

   a. Date: (Month Day Year)

3. Did the infant die <= 12 hours? N

   IF YES, COMPLETE FORM NG03E

4. Sex: 2

1 = Male	2 = Female	3 = Ambiguous

5. Ethnic Categories: 2

1 = Hispanic or Latino
2 = Not Hispanic or Latino
3 = Unknown or Not Reported

6. Racial Categories: 1

1 = Black	5 = Native Hawaiian or Other Pacific Islander
2 = White	6 = More Than One Race
3 = American Indian or Alaska Native	7 = Unknown or Not Reported
4 = Asian	

   a. If coding option 6, record all races indicated (optional)

7. Gestational age: a. Weeks: 24 b. Days: 6

8. Apgar score - 1 minute: 03

9. Apgar score - 5 minutes: 08

10. Birth resuscitation/stabilization:

    a. Oxygen? Y

    b. Bagging and mask? N

    c. CPAP? Y

    d. Intubation? Y

    e. Chest compression? N

    f. Epinephrine? N

11. Birth Weight: (grams): 0530

A. STATUS

1. Status of infant at time of completion of form: 2

1 = Discharged to home	4 = Transferred to chronic care facility
2 = Still in hospital at 120 days	5 = Death
3 = Transferred to another hospital	

2. Date of status: (b) (6)
Month Day Year

3. Weight at status (grams): 2590
4. Length at status (cm): 49.0
5. Head circumference at status (cm): 34.5

B. PULMONARY

1. Respiratory distress:
   a. Demonstrated clinical features of respiratory distress within the first 24 hrs? Y
   b. Required oxygen or postive pressure for more than 6 hours within the first 24 hours? Y
2. Did the baby receive surfactants? Y
   a. If YES, date and time of first dose: (b) (6) 12:15
   Month Day Year Hours Min
   b. Total number of surfactant doses: 003
3. Pneumothorax? N
4. Pulmonary hemorrhage? N
5. Steroids for BPD/CLD? N
   a. If YES, Date of first dose:
   Month Day Year
6. Did infant receive inhaled nitric oxide? N
   a. If YES, Date of first exposure:

C. CARDIAC

1. Patent ductus arteriosus (PDA)? Y
   If YES, treatment:
   a. Indomethacin? Y
   If YES, total number of courses 01
   b. Ibuprofin N
   If YES, total number of courses
   c. Surgery? Y

D. NEUROLOGIC

1. Was indomethacin given within the first 24 hrs for any prophylaxis? Y
   If YES,
   a. Date: (b) (6) b. Time: 20:00
   Month Day Year Hour Min
2. Were there seizures treated with an anti-convulsant for >72 hours? N

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

3. Were any cranial sonograms done within 28 days of birth? Y

   If NO, Go to Question D5

   a. If Yes, Were all studies without evidence of intracranial hemorrhage, peri-ventricular leukomalacia or ventriculomegaly? Y

   If Yes, Go to Question D5

   b. Date of sonogram for most severe findings: Month Day Year

   c. Blood/echodensity in germinal matrix/subependymal area?

	(1) RIGHT	(2) LEFT
d. Blood/echodensity in the ventricle?		
e. Ventricular size enlarged with concurrent or prior blood in the ventricles?		
f. Ventricular size enlarged without concurrent or prior blood in the ventricles?		
g. Blood/echo-density in the parenchyma?		

4. Cystic area(s) in the parenchyma within 28 days?

   If YES,

	(1) RIGHT	(2) LEFT
a. Cystic periventricular leukomalacia within 28 days?		
b. Porencephalic cyst within 28 days?		

5. Were any cranial imaging studies done after 28 days of birth? Y

   If NO, Go to Section E.

6. Cranial sonogram closest to 36 weeks postmenstrual age and after 28 days of birth:

   a. Type of imaging (1=MRI, 2=Sonogram, 3=CT scan) 2

   b. Date of image: (b) (6) [redacted]
   Month Day Year

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

c. Normal study? Y

If NO,

	(1) RIGHT	(2) LEFT
d. Ventricular size enlarged?		
e. Cystic periventricular leukomalacia?		
f. Porencephalic cyst?		

E. INFECTIO

1. Early onset septicemia/bacteremia at (<= 72 hours)? N
   If YES, organism code(s): a. b.
2. Did the infant receive antibiotics for >= 5 days, starting within the first 72 hours? Y
3. Number of episodes of late onset blood culture negative clinical infection (>=72 hours to status) treated with antibiotics for >= 5 days: 03
4. Late onset culture positive septicemia/bacteremia (>= 72 hours)? Y
   If YES,
   a. Number of episodes between day 3 and status that were treated with antibiotics for >= 5 days: 01
   b. Organism code(s) and date of first positive culture for each of episodes for which the infant was treated with antibiotics for >= 5 days:

a)Episode#	(b) Date	(1) Organism	(2) Organism	(3) Organism
1	(b) (6)	104		
2				
3				
4				
5				
6				

5. Meningitis? N
   a. If YES,

a)Episode#	(b) Date	(1) Organism	(2) Organism	(3) Organism
1				
2				

F. GASTROINTESTINAL

1. Did weight ever fall below the birth weight during the first 10 days? Y
   If YES,
   a. Lowest weight in the first 10 days? 0462
   b. Date of lowest weight in the first 10 days: (b) (6)
   c. Was birth weight regained? Y
   If YES
   d. Date birth weight first regained: (b) (6)

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

2. Did the baby receive patenteral alimentation? **Y**

   If YES,

   a. Date of first patenteral alimentation (b) (6)

   b. Total number of days: **058**

3. Did the baby receive enteral feeds? **Y**

   If YES,

   a. Date of first enteral feed: (b) (6)

   b. Did enteral feeds reach 120 ml/kg/day? **Y**

      1) If YES, date first achieved: (b) (6)

   c. Did the baby receive breast milk in the first 28 days? **Y**

      1) If YES, number of days baby received any breast milk in first 28 days: **15**

4. Proven NEC: **0**

   0 = Absent/Suspect 2 = Proved, no surgery 3 = Proved, surgery

   a. If proven NEC, Date of first episode?

      Month Day Year

5 Spontaneous gastrointestinal perforation without proven NEC? **N**

   a. If YES, date of the first spontaneous gastrointestinal perforation:

      Month Day Year

6. Did the infant have GI surgery that resulted in short gut? **N**

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

CENTER: 19 NETWORK: (b) (6) SITENM: (b) Mother's Initials: *** , Birth No: 1

G. HEARING

1. Was a Hearing screen performed? **Y**

   a. If YES, hearing screen protocol used: **2**

1 = OAE	2 = AABR	3 = ABR	4 = OAE + AABR	5 = Other

   b. Final screen results before discharge

      i) Right ear: **1**

      ii) Left ear: **1**

Results:	1. Pass	2. Fail	3. Incomplete

   c. If a failed screen in either ear, was a diagnostic ABR done prior to status?

      1) If YES, answer the following:

         i) Right ear:

         ii) Left ear:

Results:	1. Pass	2. Fail	3. Incomplete

H. OPHTHALMOLOGY

1. Was an exam performed for ROP? **Y**

   If Yes,

   a. Was ROP diagnosed in either eye? **Y**

      If Yes,

      1) Did it reach stage 3 or worse in either eye? **N**

      2) Did plus disease develop in either eye? **N**

      3) Other therapies

         (if yes, specify):

   b. Intervention Therapies:

      1. Was retinal ablation performed in either eye (laser and/or cryotherapy)? **N**

      2. Was any scleral buckle or vitrectomy performed in either eye? **N**

2. At the time of reaching status, indicate the most appropriate: **1**

   1 = Determined, favorable in both eyes

   2 = Determined, severe ROP in either eye

   3 = Undetermined ROP status in either eye (and neither had "severe ROP")

1. Determined Favorable:
   - Vessels mature (fully vascularized)
   - Vessels in zone III for two consecutive exams
   - ROP of stage 1 or 2 in zone III for two consecutive exams
   - ROP in zone II or zone III but determined to be clearly regressing

2. Determined-Severe:
   - ROP surgery
   - Retinal detachment
   - Avastin injection

3. Undetermined:
   - Immature Vessels in zone I and II
   - Immature Vessels reaching zone III for only 1 exam
   - Stage 1 or 2 ROP in zone III for only 1 exam
   - Stage 3 ROP in zone III
   - ROP in zone I or zone II
   - Plus disease

1) =	2) =	3) =
4) =	5) =	

   b) If a syndrome is coded "699", specify:

J. MAJOR SURGERY

1. Other major surgery not covered in previous sections? **Y**

   a. If YES, code:

1) =	**206**	2) =	**999**	3) =
4) =		5) =		

   i) If a major surgery is coded 999, specify:

   nissen funduplication

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

K. 36 WEEK INFORMATION

1. Status at 36 weeks: **2**

1 = Discharged 2 = In hospital 3 = Transferred 5 = Death

If "2", (In Hospital):

a. Date of 36 weeks measurement: (b) (6)
Month Day Year

b. Weight (g) **1262**

c. Length (cm): **34.0**

d. Head circumference (cm) **27.5**

L. FEEDING STATUS:

1. Type of nutrition at discharge to home. Code all that apply

(Do not complete for transfer patients):

1 = Breastmilk 2 = Formula 3 = TPN

2. If enteral, Mode:

1 = Breast 2 = Bottle 3 = NG/NJ tube 4 = Gastrostomy tube 9 = Unknown

M. TRANSFER

Complete this section if status (AI) of infant at time of completion of this form is "3" or "4".

1. Date of transfer:
Month Day Year

2. Final outcome:

1 = Died in Hospital 2 = Discharged to Home 6 = Remains in hospital at one year

a. If discharged to home, final weight at discharge (grams):

N. DISCHARGE ALIVE

Complete this section if status (Q. A1 above) of infant at time of completion of this form is "1" or if the final outcome for a transferred infant is 'Discharged to home.'

1. Date of discharge to home:
Month Day Year

2. Discharged home on continuous oxygen?

3. Discharged home on any of the following medications?

If YES,

a. Diuretics?

b. Bronchodilators?

c. Anticonvulsants?

d. Antireflux medications?

O. DEATH

1. Date of Death:
Month Day Year

a. Time of Death
Hours Minutes

2. Autopsy performed?

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

3. Contributory Cause of death

```
Malformation                                    NEC
10 = Congenital malformation                      40 = NEC
Pulmonary                                         41 = NEC with sepsis
20 = RDS                                        CNS Insult
21 = RDS with severe intracranial hemorrhage      50 = Severe intracranial
hemorrhage
22 = RDS with infection                         Other
25 = BPD                                          60 = Immaturity
26 = BPD with infection                           90 = Other
27 = BPD with severe CNS insult                   99 = Unknown
Infection
30 = Suspect sepsis/infection
31 = Proven sepsis/infection
```

4. If contributory cause of death is code "10" (Congenital malformation), or code "90" (other), specify:

5. Was respiratory support withheld or withdrawn at any time prior to death?

e. Did the patient pass the evaluation? [redacted]

IF NO to question C.1.a

f. If patient was eligible and evaluation not done, code reason: [redacted]

If 9, explain [redacted]

```
1= Increased FIO2                                  4= Parent/Physicial Refusal
2= Increased respiratory support (cpap or vent)    6= Weaned to room air on/before day of evaluation
3= Instability (including Surgery/Sepsis)          9= Other-explain
```

Form Completion Date: **09/19/2009**

CENTER: 19 NETWORK: (b) (6) SITENM: (b) Mother's Initials: , Birth No: 1

This form should be completed for all inborn infants with a gestational age of 24 0/7 to 27 6/7 weeks gestation by best obstetrical estimates and who are to receive full resuscitation.

A. INCLUSION CRITERIA

1. Inborn infant with a minimal gestational age of 24 weeks 0 days to 27 6/7 completed weeks by best obstetrical estimate? **Y**
2. Infant to receive full resuscitation as necessary? **Y**
3. Infant does not have known major congenital malformations? **Y**

If any of above questions are answered 'N' infant is NOT eligible.

B. EXCLUSION CRITERIA

1. The infant was born during a time when the research apparatus/study personnel are not available? **N**

   If Yes, indicate reason:

   1 = Equipment not available 2 = Personnel not available

C. CONSENT

1. Consent Status: **1**

   0 = Not eligible
   1 = Consent granted
   2 = Parent unavailable
   3 = Parent refused consent
   4 = Consent not requested
   5 = Physician refused consent

   a. If parent refused consent (3), consent not requested (4) or physician refused consent (5), indicate reason:

D. RANDOMIZATION

1. Was infant randomized into the study? **Y**

   If No, indicate reason(s):

   If Yes,

   a. Date: (b) (6) Month Day Year

   b. Time: **10:45** Hour Min

   c. Randomization Number (b) (6)

   d. Treatment Assignment **1**

   1= Early Extubation and CPAP 2= Early Surfactant and Ventilation

   e. Oximeter Color Code: **1**

   1= Blue 2= Orange

Initials of person completing this form: **KRF**

SUPP02 Form Completion Date: **11/16/2006**

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

CENTER: 19 NETWORK: (b) (6) SITENM (b) (6) Mother's Initials: , Birth No: 1

A. DELIVERY ROOM INFORMATION

1. Date and time of delivery:

a. Date: (b) (6) (Month Day Year) b. Time: 10:45 (Hour Min)

2. Was CPAP initiated in the DR? Y

If Yes, Date and time of CPAP initiation:

a. Date: (b) (6) (Month Day Year) b. Time: 10:45 (Hour Min)

c. Device: 1

1 = Neopuff 2 = Ventilator 3 = Anesthesia Bag 4 = Bubble 9 = Other

If (9) Other (specify device)

3. Was positive pressure ventilation (PPV) initiated in the DR? Y

4. Was positive and expiratory pressure (PEEP) used in the DR? Y

If Yes,

a. Maximum PEEP: 05

5. Was intubation attempted in the DR? N

If Yes, was the intubation successful?

6. Indication for intubation:

1=Surfactant administration 2=Resuscitation 3= Other (Specify) 4 = As required by randomization assignment

If (2) Resuscitation,

a. Low HR?

b. Poor color?

c. Apnea?

d. Other?

If Other specify:

If (3) Other, specify:

7. Did the infant receive surfactant in the DR?

If Yes, Date and time of administration:

a. Date: (Month Day Year) b. Time: (Hour Min)

c. Type:

1 = Infasurf 2 = Curosurf 3 = Survanta 4 = Exosurf 5 = Other (Specify)

If (5) Other (specify type)

CENTER: 19 NETWORK: (b) (6) SITENM: [redacted] Mother's Initials: , Birth No: 1

A. NICU ADMISSION

1. Date and time of NICU admission

   a. Date: (b) (6) (Month Day Year) b. Time: 11:03 (Hour Min)

2. Respiratory Support on admission to the NICU: 4

   1 = HVF 2 = CV 3 = Nasal SIMV 4 = CPAP 5 = NC 6 = Hood 7 = No Support

3. SaO2: 096

4. FiO2: 0.28

5. Was blood gas done after admission to the NICU? Y

   If Yes, record the first blood gas after admission:

   a. Date: (b) (6) (Month Day Year) b. Time: 12:10 (Hour Min)

   c. Source: 1

      1= Arterial 2= Venous 3= Capillary

   d. pH: 7.24

   e. pCO2: 059

   f. pO2: 066

   g. FiO2: 0.24

6. Date and time the study oximeter was placed on this infant.

   a. Date: (b) (6) (Month Day Year) b. Time: 10:55 (Hour Min)

   c. Serial number: 316779

B. NICU PROCEDURES

1. Was infant intubated for the first time within the first 14 days after admission to the NICU? Y

   If Yes,

   a. Date: (b) (6) (Month Day Year) b. Time: **:** (Hour Min)

   c. Indication for intubation:

      1. Surfactant? N
      2. FiO2 > .50 to maintain SaO2 >= 88% N
      3. pCO2 > 65 on single blood gas? N
      4. Apnea requiring bag and mask ventilation? N
      5. If NO to all above, state reason: 3

         1= Hemodynamic instability 2 = Clinical shock/sepsis 3 = Other

         If Other (3), specify

         frequent apnea and bradycardia

A. MATERNAL INFORMATION

1. Mother's age (years): 27
2. Maternal Zip Code: (b) (6)
3. Pregnancy history (include this pregnancy):
   a. Gravida: 02
   b. Parity: 01
4. Marital Status: 1

1 = Married	2 = Single	6 = Unknown

5. Highest level of education achieved by the Biological Mother: 8

1 = < 7th grade	5 = Partial college
2 = 7th to 9th grade	6 = College degree
3 = 10th to 12th grade	7 = Graduate degree
4 = High School degree	8 = Unknown

6. Mother's medical insurance: 9

1 = Medicaid	6 = Unknown
3 = Private	9 = Other
5 = Self-pay/uninsured	

B. PREGNANCY COMPLICATIONS

1. Multiple birth? N
   a. If YES, Number of fetuses:
2. Mother has evidence of at least one prenatal visit in this pregnancy? Y
3. Diabetes - insulin dependent? N
   If YES, was insulin given prior to pregnancy?
4. Hypertension? N
   a. Hypertension existed prior to pregnancy?
5. Antepartum hemorrhage? N
6. Was Chorioamnionitis documented in the mother's medical record? Y
7. Was a placental pathology performed? N
   If YES,
   a. Was histologic chorioamnionitis documented?

C. LABOR AND DELIVERY

1. Was there a rupture of membranes prior to delivery? Y
   If Yes,
   a. Date: (b) (6) (Month Day Year) b. Time: **:** (Hour Min)
   c. If date and/or time unknown, were ROM estimated at > 18 hours? Y
2. Were steroids given prior to delivery to accelerate maturity? Y
   a. If YES, Type of antenatal steroid given: 1

1 = Betamethasone	2 = Dexamethasone	3 = Both	4 = UK

   b. Was a complete course of steriods given prior to delivery? U

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

3. Were maternal antibiotics used during the admission resulting in this delivery? Y

   a. If YES, were antibiotics given within 72 hrs prior to delivery? Y

   1. 01 3. 49 5.

   2. 32 4. 6.

4. Final mode of delivery: 1

1 = Vaginal vertex	2 = Vaginal breech	3 = Cesarean section	4 = Vaginal NOS	5 = Unknown

D. NEONATAL INFORMATION

1. Date and time of birth:

   a. Date: (b) (6) (Month Day Year) b. Time: 10:45 (Hour Min)

2. Was the infant outborn? N

   If YES, date and time admitted to NICU:

   a. Date:

   Month Day Year

3. Did the infant die <= 12 hours? N

   IF YES, COMPLETE FORM NG03E

4. Sex: 2

1 = Male	2 = Female	3 = Ambiguous

5. Ethnic Categories: 2

1 = Hispanic or Latino
2 = Not Hispanic or Latino
3 = Unknown or Not Reported

6. Racial Categories: 1

1 = Black	5 = Native Hawaiian or Other Pacific Islander
2 = White	6 = More Than One Race
3 = American Indian or Alaska Native	7 = Unknown or Not Reported
4 = Asian	

   a. If coding option 6, record all races indicated (optional)

7. Gestational age: a. Weeks: 27 b. Days: 3

8. Apgar score - 1 minute: 09

9. Apgar score - 5 minutes: 09

10. Birth resuscitation/stabilization:

    a. Oxygen? Y

    b. Bagging and mask? N

    c. CPAP? Y

    d. Intubation? N

    e. Chest compression? N

    f. Epinephrine? N

11. Birth Weight: (grams): 1035

A. STATUS

1. Status of infant at time of completion of form: 3

1 = Discharged to home	4 = Transferred to chronic care facility
2 = Still in hospital at 120 days	5 = Death
3 = Transferred to another hospital	

2. Date of status: (b) (6) Month Day Year
3. Weight at status (grams): 1071
4. Length at status (cm): **.*
5. Head circumference at status (cm): **.*

B. PULMONARY

1. Respiratory distress:
   a. Demonstrated clinical features of respiratory distress within the first 24 hrs? Y
   b. Required oxygen or postive pressure for more than 6 hours within the first 24 hours? Y
2. Did the baby receive surfactants? N
   a. If YES, date and time of first dose: Month Day Year Hours Min
   b. Total number of surfactant doses:
3. Pneumothorax? N
4. Pulmonary hemorrhage? N
5. Steroids for BPD/CLD? N
   a. If YES, Date of first dose: Month Day Year
6. Did infant receive inhaled nitric oxide? N
   a. If YES, Date of first exposure:

C. CARDIAC

1. Patent ductus arteriosus (PDA)? N
   If YES, treatment:
   a. Indomethacin?
   If YES, total number of courses
   b. Ibuprofin
   If YES, total number of courses
   c. Surgery?

D. NEUROLOGIC

1. Was indomethacin given within the first 24 hrs for any prophylaxis? N
   If YES,
   a. Date: Month Day Year b. Time: Hour Min
2. Were there seizures treated with an anti-convulsant for >72 hours? N

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

3. Were any cranial sonograms done within 28 days of birth? Y

   If NO, Go to Question D5

   a. If Yes, Were all studies without evidence of intracranial hemorrhage, peri-ventricular leukomalacia or ventriculomegaly? Y

   If Yes, Go to Question D5

   b. Date of sonogram for most severe findings: Month Day Year

   c. Blood/echodensity in germinal matrix/subependymal area?

	(1) RIGHT	(2) LEFT
d. Blood/echodensity in the ventricle?		
e. Ventricular size enlarged with concurrent or prior blood in the ventricles?		
f. Ventricular size enlarged without concurrent or prior blood in the ventricles?		
g. Blood/echo-density in the parenchyma?		

4. Cystic area(s) in the parenchyma within 28 days?

   If YES,

	(1) RIGHT	(2) LEFT
a. Cystic periventricular leukomalacia within 28 days?		
b. Porencephalic cyst within 28 days?		

5. Were any cranial imaging studies done after 28 days of birth? Y

   If NO, Go to Section E.

6. Cranial sonogram closest to 36 weeks postmenstrual age and after 28 days of birth:

   a. Type of imaging (1=MRI, 2=Sonogram, 3=CT scan) 2

   b. Date of image: (b) (6) Month Day Year

d. Ventricular size enlarged?		
e. Cystic periventricular leukomalacia?		
f. Porencephalic cyst?		

E. INFECTIO

1. Early onset septicemia/bacteremia at (<= 72 hours)? N
   If YES, organism code(s): a. b.
2. Did the infant receive antibiotics for >= 5 days, starting within the first 72 hours? Y
3. Number of episodes of late onset blood culture negative clinical infection (>=72 hours to status) treated with antibiotics for >= 5 days: 00
4. Late onset culture positive septicemia/bacteremia (>= 72 hours)? Y
   If YES,
   a. Number of episodes between day 3 and status that were treated with antibiotics for >= 5 days: 01
   b. Organism code(s) and date of first positive culture for each of episodes for which the infant was treated with antibiotics for >= 5 days:

a)Episode#	(b) Date	(1) Organism	(2) Organism	(3) Organism
1	(b) (6)	699		
2				
3				
4				
5				
6				

5. Meningitis? Y
   a. If YES,

a)Episode#	(b) Date	(1) Organism	(2) Organism	(3) Organism
1	(b) (6)	104		
2				

F. GASTROINTESTINAL

1. Did weight ever fall below the birth weight during the first 10 days? Y
   If YES,
   a. Lowest weight in the first 10 days? 0851
   b. Date of lowest weight in the first 10 days: (b) (6)
   c. Was birth weight regained? Y
   If YES
   d. Date birth weight first regained: (b) (6)

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

2. Did the baby receive patenteral alimentation? Y

   If YES,

   a. Date of first patenteral alimentation (b) (6)

   b. Total number of days: 014

3. Did the baby receive enteral feeds? Y

   If YES,

   a. Date of first enteral feed: (b) (6)

   b. Did enteral feeds reach 120 ml/kg/day? Y

      1) If YES, date first achieved: (b) (6)

   c. Did the baby receive breast milk in the first 28 days? Y

      1) If YES, number of days baby received any breast milk in first 28 days: 24

4. Proven NEC: 0

   0 = Absent/Suspect 2 = Proved, no surgery 3 = Proved, surgery

   a. If proven NEC, Date of first episode?

      Month Day Year

5 Spontaneous gastrointestinal perforation without proven NEC? N

   a. If YES, date of the first spontaneous gastrointestinal perforation:

      Month Day Year

6. Did the infant have GI surgery that resulted in short gut? N

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

CENTER: 19 NETWORK: (b) (6) SITENM: (b) Mother's Initials: *** , Birth No: 1

G. HEARING

1. Was a Hearing screen performed? N

a. If YES, hearing screen protocol used:

1 = OAE	2 = AABR	3 = ABR	4 = OAE + AABR	5 = Other

b. Final screen results before discharge

i) Right ear:

ii) Left ear:

Results:	1. Pass	2. Fail	3. Incomplete

c. If a failed screen in either ear, was a diagnostic ABR done prior to status?

1) If YES, answer the following:

i) Right ear:

ii) Left ear:

Results:	1. Pass	2. Fail	3. Incomplete

H. OPHTHALMOLOGY

1. Was an exam performed for ROP? N

If Yes,

a. Was ROP diagnosed in either eye?

If Yes,

1) Did it reach stage 3 or worse in either eye?

2) Did plus disease develop in either eye?

3) Other therapies

(if yes, specify):

b. Intervention Therapies:

1. Was retinal ablation performed in either eye (laser and/or cryotherapy)?

2. Was any scleral buckle or vitrectomy performed in either eye?

2. At the time of reaching status, indicate the most appropriate:

1 = Determined, favorable in both eyes

2 = Determined, severe ROP in either eye

3 = Undetermined ROP status in either eye (and neither had "severe ROP")

1. Determined Favorable:
   - Vessels mature (fully vascularized)
   - Vessels in zone III for two consecutive exams
   - ROP of stage 1 or 2 in zone III for two consecutive exams
   - ROP in zone II or zone III but determined to be clearly regressing

2. Determined-Severe:
   - ROP surgery
   - Retinal detachment
   - Avastin injection

3. Undetermined:
   - Immature Vessels in zone I and II
   - Immature Vessels reaching zone III for only 1 exam
   - Stage 1 or 2 ROP in zone III for only 1 exam
   - Stage 3 ROP in zone III
   - ROP in zone I or zone II
   - Plus disease

K. 36 WEEK INFORMATION

1. Status at 36 weeks: 3

1 = Discharged 2 = In hospital 3 = Transferred 5 = Death

If "2", (In Hospital):

a. Date of 36 weeks measurement: Month Day Year

b. Weight (g)

c. Length (cm):

d. Head circumference (cm)

L. FEEDING STATUS:

1. Type of nutrition at discharge to home. Code all that apply

(Do not complete for transfer patients):

1 = Breastmilk 2 = Formula 3 = TPN

2. If enteral, Mode:

1 = Breast 2 = Bottle 3 = NG/NJ tube 4 = Gastrostomy tube 9 = Unknown

M. TRANSFER

Complete this section if status (AI) of infant at time of completion of this form is "3" or "4".

1. Date of transfer: (b) (6) Month Day Year

2. Final outcome: 2

1 = Died in Hospital 2 = Discharged to Home 6 = Remains in hospital at one year

a. If discharged to home, final weight at discharge (grams): 2115

N. DISCHARGE ALIVE

Complete this section if status (Q. A1 above) of infant at time of completion of this form is "1" or if the final outcome for a transferred infant is 'Discharged to home.'

1. Date of discharge to home: (b) (6) Month Day Year

2. Discharged home on continuous oxygen? Y

3. Discharged home on any of the following medications? Y

If YES,

a. Diuretics? Y

b. Bronchodilators? N

c. Anticonvulsants? N

d. Antireflux medications? N

O. DEATH

1. Date of Death: Month Day Year

a. Time of Death Hours Minutes

2. Autopsy performed?

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

This form should be completed for all inborn infants with a gestational age of 24 0/7 to 27 6/7 weeks gestation by best obstetrical estimates and who are to receive full resuscitation.

A. INCLUSION CRITERIA

1. Inborn infant with a minimal gestational age of 24 weeks 0 days to 27 6/7 completed weeks by best obstetrical estimate? **Y**
2. Infant to receive full resuscitation as necessary? **Y**
3. Infant does not have known major congenital malformations? **Y**

If any of above questions are answered 'N' infant is NOT eligible.

B. EXCLUSION CRITERIA

1. The infant was born during a time when the research apparatus/study personnel are not available? **N**

   If Yes, indicate reason:

   1 = Equipment not available 2 = Personnel not available

C. CONSENT

1. Consent Status: **1**

   0 = Not eligible
   1 = Consent granted
   2 = Parent unavailable
   3 = Parent refused consent
   4 = Consent not requested
   5 = Physician refused consent

   a. If parent refused consent (3), consent not requested (4) or physician refused consent (5), indicate reason:

D. RANDOMIZATION

1. Was infant randomized into the study? **Y**

   If No, indicate reason(s):

   If Yes,

   a. Date: (b) (6)
   Month Day Year

   b. Time: **06:32**
   Hour Min

   c. Randomization Number (b) (6)

   d. Treatment Assignment **2**

   1= Early Extubation and CPAP 2= Early Surfactant and Ventilation

   e. Oximeter Color Code: **2**

   1= Blue 2= Orange

Initials of person completing this form: **KRF**

Study Day 065

Date (b) (6)
Month Day Year

1. Scheduled Time: 06:00
06:00 (time measured)

(a) Highest Level of Support (Mode) 9

(b) Oxygen

(c) Flow Rate (NC Only)

(d) Oximeter Alarm Check

2. Scheduled Time:
12:00 (time measured)

(a) Highest Level of Support (Mode)

(b) Oxygen

(c) Flow Rate (NC Only)

(d) Oximeter Alarm Check

3. Scheduled Time:
18:00 (time measured)

(a) Highest Level of Support (Mode)

(b) Oxygen

(c) Flow Rate (NC Only)

(d) Oximeter Alarm Check

4. Scheduled Time:
23:59 (time measured)

(a) Highest Level of Support (Mode)

(b) Oxygen

(c) Flow Rate (NC Only)

(d) Oximeter Alarm Check

** Mode 1= HFV 2= CV 3= Nasal SIMV 4= CPAP 5= NC 6=Hood 7=No Support 8= Infant temporarily out of unit 9 = No Support all day and not on study oximeter

Form Completion Date: 08/14/2007

CENTER: 19 NETWORK: (b) (6) SITENM (b) (6) Mother's Initials: , Birth No: 1

A. MATERNAL INFORMATION

1. Mother's age (years): 18
2. Maternal Zip Code: (b) (6)
3. Pregnancy history (include this pregnancy):
   a. Gravida: 01
   b. Parity: 01
4. Marital Status: 2

1 = Married	2 = Single	6 = Unknown

5. Highest level of education achieved by the Biological Mother: 3

1 = < 7th grade	5 = Partial college
2 = 7th to 9th grade	6 = College degree
3 = 10th to 12th grade	7 = Graduate degree
4 = High School degree	8 = Unknown

6. Mother's medical insurance: 6

1 = Medicaid	6 = Unknown
3 = Private	9 = Other
5 = Self-pay/uninsured	

B. PREGNANCY COMPLICATIONS

1. Multiple birth? N
   a. If YES, Number of fetuses:
2. Mother has evidence of at least one prenatal visit in this pregnancy? Y
3. Diabetes - insulin dependent? N
   If YES, was insulin given prior to pregnancy?
4. Hypertension? N
   a. Hypertension existed prior to pregnancy?
5. Antepartum hemorrhage? Y
6. Was Chorioamnionitis documented in the mother's medical record? N
7. Was a placental pathology performed? Y
   If YES,
   a. Was histologic chorioamnionitis documented? Y

C. LABOR AND DELIVERY

1. Was there a rupture of membranes prior to delivery? N
   If Yes,
   a. Date: Month Day Year
   b. Time: Hour Min
   c. If date and/or time unknown, were ROM estimated at > 18 hours?
2. Were steroids given prior to delivery to accelerate maturity? Y
   a. If YES, Type of antenatal steroid given: 1

1 = Betamethasone	2 = Dexamethasone	3 = Both	4 = UK

   b. Was a complete course of steriods given prior to delivery? N

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

CENTER: 19 NETWORK: (b) (6) SITENM (b) (6) Mother's Initials: , Birth No: 1

3. Were maternal antibiotics used during the admission resulting in this delivery? Y

   a. If YES, were antibiotics given within 72 hrs prior to delivery? Y

   1. 49 3. 5.

   2. 4. 6.

4. Final mode of delivery: 3

1 = Vaginal vertex	2 = Vaginal breech	3 = Cesarean section	4 = Vaginal NOS	5 = Unknown

D. NEONATAL INFORMATION

1. Date and time of birth:

   a. Date: (b) (6) (Month Day Year) b. Time: 06:32 (Hour Min)

2. Was the infant outborn? N

   If YES, date and time admitted to NICU:

   a. Date: (Month Day Year)

3. Did the infant die <= 12 hours? N

   IF YES, COMPLETE FORM NG03E

4. Sex: 2

1 = Male	2 = Female	3 = Ambiguous

5. Ethnic Categories: 2

1 = Hispanic or Latino
2 = Not Hispanic or Latino
3 = Unknown or Not Reported

6. Racial Categories: 1

1 = Black	5 = Native Hawaiian or Other Pacific Islander
2 = White	6 = More Than One Race
3 = American Indian or Alaska Native	7 = Unknown or Not Reported
4 = Asian	

   a. If coding option 6, record all races indicated (optional)

7. Gestational age: a. Weeks: 27 b. Days: 5

8. Apgar score - 1 minute: 04

9. Apgar score - 5 minutes: 07

10. Birth resuscitation/stabilization:

   a. Oxygen? Y

   b. Bagging and mask? N

   c. CPAP? N

   d. Intubation? Y

   e. Chest compression? N

   f. Epinephrine? N

A. STATUS

1. Status of infant at time of completion of form: **1**

1 = Discharged to home	4 = Transferred to chronic care facility
2 = Still in hospital at 120 days	5 = Death
3 = Transferred to another hospital	

2. Date of status: (b) (6) Month Day Year

3. Weight at status (grams): **1830**
4. Length at status (cm): **39.0**
5. Head circumference at status (cm): **29.5**

B. PULMONARY

1. Respiratory distress:
   a. Demonstrated clinical features of respiratory distress within the first 24 hrs? **Y**
   b. Required oxygen or postive pressure for more than 6 hours within the first 24 hours? **Y**
2. Did the baby receive surfactants? **Y**
   a. If YES, date and time of first dose: (b) (6) Month Day Year ****:**** Hours Min
   b. Total number of surfactant doses: **001**
3. Pneumothorax? **N**
4. Pulmonary hemorrhage? **N**
5. Steroids for BPD/CLD? **N**
   a. If YES, Date of first dose: Month Day Year
6. Did infant receive inhaled nitric oxide? **N**
   a. If YES, Date of first exposure:

C. CARDIAC

1. Patent ductus arteriosus (PDA)? **Y**
   If YES, treatment:
   a. Indomethacin? **N**
   If YES, total number of courses
   b. Ibuprofin **Y**
   If YES, total number of courses **01**
   c. Surgery? **N**

D. NEUROLOGIC

1. Was indomethacin given within the first 24 hrs for any prophylaxis? **N**
   If YES,
   a. Date: Month Day Year b. Time: Hour Min
2. Were there seizures treated with an anti-convulsant for >72 hours? **N**

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

3. Were any cranial sonograms done within 28 days of birth? Y

   If NO, Go to Question D5

   a. If Yes, Were all studies without evidence of intracranial hemorrhage, peri-ventricular leukomalacia or ventriculomegaly? Y

   If Yes, Go to Question D5

   b. Date of sonogram for most severe findings: Month Day Year

   c. Blood/echodensity in germinal matrix/subependymal area?

	(1) RIGHT	(2) LEFT
d. Blood/echodensity in the ventricle?		
e. Ventricular size enlarged with concurrent or prior blood in the ventricles?		
f. Ventricular size enlarged without concurrent or prior blood in the ventricles?		
g. Blood/echo-density in the parenchyma?		

4. Cystic area(s) in the parenchyma within 28 days?

   If YES,

	(1) RIGHT	(2) LEFT
a. Cystic periventricular leukomalacia within 28 days?		
b. Porencephalic cyst within 28 days?		

5. Were any cranial imaging studies done after 28 days of birth? Y

   If NO, Go to Section E.

6. Cranial sonogram closest to 36 weeks postmenstrual age and after 28 days of birth:

   a. Type of imaging (1=MRI, 2=Sonogram, 3=CT scan) 2

   b. Date of image: (b) (6)
   Month Day Year

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

c. Normal study? Y

If NO,

	(1) RIGHT	(2) LEFT
d. Ventricular size enlarged?		
e. Cystic periventricular leukomalacia?		
f. Porencephalic cyst?		

E. INFECTIO

1. Early onset septicemia/bacteremia at (<= 72 hours)? N
   If YES, organism code(s): a. b.
2. Did the infant receive antibiotics for >= 5 days, starting within the first 72 hours? N
3. Number of episodes of late onset blood culture negative clinical infection (>=72 hours to status) treated with antibiotics for >= 5 days: 01
4. Late onset culture positive septicemia/bacteremia (>= 72 hours)? N
   If YES,
   a. Number of episodes between day 3 and status that were treated with antibiotics for >= 5 days:
   b. Organism code(s) and date of first positive culture for each of episodes for which the infant was treated with antibiotics for >= 5 days:

a)Episode#	(b) Date	(1) Organism	(2) Organism	(3) Organism
1				
2				
3				
4				
5				
6				

5. Meningitis? N
   a. If YES,

a)Episode#	(b) Date	(1) Organism	(2) Organism	(3) Organism
1				
2				

F. GASTROINTESTINAL

1. Did weight ever fall below the birth weight during the first 10 days? Y
   If YES,
   a. Lowest weight in the first 10 days? 0781
   b. Date of lowest weight in the first 10 days: (b) (6)
   c. Was birth weight regained? Y
   If YES
   d. Date birth weight first regained: (b) (6)

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

2. Did the baby receive patenteral alimentation? **Y**

   If YES,

   a. Date of first patenteral alimentation **(b) (6)**

   b. Total number of days: **039**

3. Did the baby receive enteral feeds? **Y**

   If YES,

   a. Date of first enteral feed: **(b) (6)**

   b. Did enteral feeds reach 120 ml/kg/day? **Y**

      1) If YES, date first achieved: **(b) (6)**

   c. Did the baby receive breast milk in the first 28 days? **Y**

      1) If YES, number of days baby received any breast milk in first 28 days: **03**

4. Proven NEC: **0**

   0 = Absent/Suspect 2 = Proved, no surgery 3 = Proved, surgery

   a. If proven NEC, Date of first episode?

      Month Day Year

5 Spontaneous gastrointestinal perforation without proven NEC? **N**

   a. If YES, date of the first spontaneous gastrointestinal perforation:

      Month Day Year

6. Did the infant have GI surgery that resulted in short gut? **N**

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

CENTER: 19 NETWORK: (b) (6) SITENM: (b) Mother's Initials: Birth No: 1

G. HEARING

1. Was a Hearing screen performed? **Y**

   a. If YES, hearing screen protocol used: **2**

   1 = OAE 2 = AABR 3 = ABR 4 = OAE + AABR 5 = Other

   b. Final screen results before discharge

      i) Right ear: **1**

      ii) Left ear: **1**

      Results: 1. Pass 2. Fail 3. Incomplete

   c. If a failed screen in either ear, was a diagnostic ABR done prior to status?

      1) If YES, answer the following:

         i) Right ear:

         ii) Left ear:

      Results: 1. Pass 2. Fail 3. Incomplete

H. OPHTHALMOLOGY

1. Was an exam performed for ROP? **Y**

   If Yes,

   a. Was ROP diagnosed in either eye? **Y**

      If Yes,

      1) Did it reach stage 3 or worse in either eye? **Y**

      2) Did plus disease develop in either eye? **N**

      3) Other therapies

         (if yes, specify):

   b. Intervention Therapies:

      1. Was retinal ablation performed in either eye (laser and/or cryotherapy)? **N**

      2. Was any scleral buckle or vitrectomy performed in either eye? **N**

2. At the time of reaching status, indicate the most appropriate: **3**

   1 = Determined, favorable in both eyes

   2 = Determined, severe ROP in either eye

   3 = Undetermined ROP status in either eye (and neither had "severe ROP")

```
1. Determined Favorable:
   -    Vessels mature (fully vascularized)
   -    Vessels in zone III for two consecutive exams
   -    ROP of stage 1 or 2 in zone III for two consecutive exams
   -    ROP in zone II or zone III but determined to be clearly regressing
```

```
2.  Determined-Severe:
    -    ROP surgery
    -    Retinal detachment
    -    Avastin injection
```

```
3.  Undetermined:
    -    Immature Vessels in zone I and II
    -    Immature Vessels reaching zone III for only 1 exam
    -    Stage 1 or 2 ROP in zone III for only 1 exam
    -    Stage 3 ROP in zone III
    -    ROP in zone I or zone II
    -    Plus disease
```

CENTER: 19 NETWORK: (b) (6) SITENM (b) (6) Mother's Initials: , Birth No: 1

K. 36 WEEK INFORMATION

1. Status at 36 weeks: **2**

1 = Discharged 2 = In hospital 3 = Transferred 5 = Death

If "2", (In Hospital):

a. Date of 36 weeks measurement: (b) (6)
Month Day Year

b. Weight (g) **1732**

c. Length (cm): **39.0**

d. Head circumference (cm) **29.5**

L. FEEDING STATUS:

1. Type of nutrition at discharge to home. Code all that apply **2**

(Do not complete for transfer patients):

1 = Breastmilk 2 = Formula 3 = TPN

2. If enteral, Mode: **2**

1 = Breast 2 = Bottle 3 = NG/NJ tube 4 = Gastrostomy tube 9 = Unknown

M. TRANSFER

Complete this section if status (AI) of infant at time of completion of this form is "3" or "4".

1. Date of transfer:
Month Day Year

2. Final outcome:

1 = Died in Hospital 2 = Discharged to Home 6 = Remains in hospital at one year

a. If discharged to home, final weight at discharge (grams):

N. DISCHARGE ALIVE

Complete this section if status (Q. A1 above) of infant at time of completion of this form is "1" or if the final outcome for a transferred infant is 'Discharged to home.'

1. Date of discharge to home: (b)
Month Day Year

2. Discharged home on continuous oxygen? **N**

3. Discharged home on any of the following medications? **N**

If YES,

a. Diuretics?

b. Bronchodilators?

c. Anticonvulsants?

d. Antireflux medications?

O. DEATH

1. Date of Death:
Month Day Year

a. Time of Death
Hours Minutes

2. Autopsy performed?

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

CENTER: 19 NETWORK: (b) (6) SITENM: [redacted] Mother's Initials: , Birth No: 1

3. Contributory Cause of death

```
Malformation                                    NEC
10 = Congenital malformation                      40 = NEC
Pulmonary                                         41 = NEC with sepsis
20 = RDS                                        CNS Insult
21 = RDS with severe intracranial hemorrhage      50 = Severe intracranial
hemorrhage                                      Other
22 = RDS with infection                           60 = Immaturity
25 = BPD                                          90 = Other
26 = BPD with infection                           99 = Unknown
27 = BPD with severe CNS insult
Infection
30 = Suspect sepsis/infection
31 = Proven sepsis/infection
```

4. If contributory cause of death is code "10" (Congenital malformation), or code "90" (other), specify:

5. Was respiratory support withheld or withdrawn at any time prior to death?

CENTER: 19 NETWORK: (b) (6) SITENM (b) (6) Mother's Initials: *** , Birth No: 1

A. NICU ADMISSION

1. Date and time of NICU admission

   a. Date: (b) (6) (Month Day Year) b. Time: 19:00 (Hour Min)

2. Respiratory Support on admission to the NICU: 2

   1 = HVF 2 = CV 3 = Nasal SIMV 4 = CPAP 5 = NC 6 = Hood 7 = No Support

3. SaO2: 092

4. FiO2: 0.40

5. Was blood gas done after admission to the NICU? Y

   If Yes, record the first blood gas after admission:

   a. Date: (b) (6) (Month Day Year) b. Time: 20:00 (Hour Min)

   c. Source: 1

      1= Arterial 2= Venous 3= Capillary

   d. pH: 7.05

   e. pCO2: 078

   f. pO2: 083

   g. FiO2: 0.40

6. Date and time the study oximeter was placed on this infant.

   a. Date: (b) (6) (Month Day Year) b. Time: 19:00 (Hour Min)

   c. Serial number: 316779

B. NICU PROCEDURES

1. Was infant intubated for the first time within the first 14 days after admission to the NICU? N

   If Yes,

   a. Date: (Month Day Year) b. Time: (Hour Min)

   c. Indication for intubation:

      1. Surfactant?
      2. FiO2 > .50 to maintain SaO2 >= 88%
      3. pCO2 > 65 on single blood gas?
      4. Apnea requiring bag and mask ventilation?
      5. If NO to all above, state reason:

         1= Hemodynamic instability 2 = Clinical shock/sepsis 3 = Other

         If Other (3), specify

CENTER: 19 NETWORK: (b) (6) SITENM: [redacted] Mother's Initials: *** , Birth No: 1

Complete this question only if Q.B.1 is YES,

2. Was a blood gas done within 30 minutes prior to intubation?

If Yes,

a. Date: Month Day Year b. Time: Hour Min

c. Source

1= Arterial 2= Venous 3= Capillary

d. pH

e. pCO2

f. pO2

g. FiO2

3. Was Surfactant given in the NICU? Y

If Yes, record the following for each dose: If more than 4 doses given see FORM SUPP04a

a) Dose#	b) Date:	c) Time:	d) Type:
1	(b) (6)	11:01	1
2			
3			
4			

*1 = Infasurf 2 = Curosurf 3 = Survanta 4 = Exosurf 5 = Other (Specify)

If Other (5), specify

CENTER: 19 NETWORK: (b) (6) SITENM: (b) (6) Mother's Initials: *** Birth No: 1

A. MATERNAL INFORMATION

1. Mother's age (years): 32
2. Maternal Zip Code: (b) (6)
3. Pregnancy history (include this pregnancy):
   a. Gravida: 02
   b. Parity: 02
4. Marital Status: 1

1 = Married	2 = Single	6 = Unknown

5. Highest level of education achieved by the Biological Mother: 8

1 = < 7th grade	5 = Partial college
2 = 7th to 9th grade	6 = College degree
3 = 10th to 12th grade	7 = Graduate degree
4 = High School degree	8 = Unknown

6. Mother's medical insurance: 3

1 = Medicaid	6 = Unknown
3 = Private	9 = Other
5 = Self-pay/uninsured	

B. PREGNANCY COMPLICATIONS

1. Multiple birth? Y
   a. If YES, Number of fetuses: 2
2. Mother has evidence of at least one prenatal visit in this pregnancy? Y
3. Diabetes - insulin dependent? N
   If YES, was insulin given prior to pregnancy?
4. Hypertension? N
   a. Hypertension existed prior to pregnancy?
5. Antepartum hemorrhage? Y
6. Was Chorioamnionitis documented in the mother's medical record? N
7. Was a placental pathology performed? Y
   If YES,
   a. Was histologic chorioamnionitis documented? N

C. LABOR AND DELIVERY

1. Was there a rupture of membranes prior to delivery? N
   If Yes,
   a. Date: Month Day Year
   b. Time: Hour Min
   c. If date and/or time unknown, were ROM estimated at > 18 hours?
2. Were steroids given prior to delivery to accelerate maturity? Y
   a. If YES, Type of antenatal steroid given: 1

1 = Betamethasone	2 = Dexamethasone	3 = Both	4 = UK

   b. Was a complete course of steriods given prior to delivery? Y

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

3. Were maternal antibiotics used during the admission resulting in this delivery? Y

   a. If YES, were antibiotics given within 72 hrs prior to delivery? Y

   1. 01 3. 5.

   2. 4. 6.

4. Final mode of delivery: 3

1 = Vaginal vertex	2 = Vaginal breech	3 = Cesarean section	4 = Vaginal NOS	5 = Unknown

D. NEONATAL INFORMATION

1. Date and time of birth:

   a. Date: (b) (6) (Month Day Year) b. Time: 18:31 (Hour Min)

2. Was the infant outborn? N

   If YES, date and time admitted to NICU:

   a. Date: (Month Day Year)

3. Did the infant die <= 12 hours? N

   IF YES, COMPLETE FORM NG03E

4. Sex: 1

1 = Male	2 = Female	3 = Ambiguous

5. Ethnic Categories: 2

1 = Hispanic or Latino
2 = Not Hispanic or Latino
3 = Unknown or Not Reported

6. Racial Categories: 7

1 = Black	5 = Native Hawaiian or Other Pacific Islander
2 = White	6 = More Than One Race
3 = American Indian or Alaska Native	7 = Unknown or Not Reported
4 = Asian	

   a. If coding option 6, record all races indicated (optional)

7. Gestational age: a. Weeks: 24 b. Days: 2

8. Apgar score - 1 minute: 01

9. Apgar score - 5 minutes: 05

10. Birth resuscitation/stabilization:

    a. Oxygen? Y

    b. Bagging and mask? Y

    c. CPAP? N

    d. Intubation? Y

    e. Chest compression? N

    f. Epinephrine? N

11. Birth Weight: (grams): 0750

A. STATUS

1. Status of infant at time of completion of form: 2

1 = Discharged to home	4 = Transferred to chronic care facility
2 = Still in hospital at 120 days	5 = Death
3 = Transferred to another hospital	

2. Date of status: (b) (6) (Month Day Year)
3. Weight at status (grams): 2065
4. Length at status (cm): 40.0
5. Head circumference at status (cm): 30.5

B. PULMONARY

1. Respiratory distress:
   a. Demonstrated clinical features of respiratory distress within the first 24 hrs? Y
   b. Required oxygen or postive pressure for more than 6 hours within the first 24 hours? Y
2. Did the baby receive surfactants? Y
   a. If YES, date and time of first dose: (b) (6) (Month Day Year) **:** (Hours Min)
   b. Total number of surfactant doses: 004
3. Pneumothorax? N
4. Pulmonary hemorrhage? N
5. Steroids for BPD/CLD? N
   a. If YES, Date of first dose: (Month Day Year)
6. Did infant receive inhaled nitric oxide? N
   a. If YES, Date of first exposure:

C. CARDIAC

1. Patent ductus arteriosus (PDA)? Y
   If YES, treatment:
   a. Indomethacin? N
   If YES, total number of courses
   b. Ibuprofin Y
   If YES, total number of courses 03
   c. Surgery? N

D. NEUROLOGIC

1. Was indomethacin given within the first 24 hrs for any prophylaxis? Y
   If YES,
   a. Date: (b) (6) (Month Day Year) b. Time: **:** (Hour Min)
2. Were there seizures treated with an anti-convulsant for >72 hours? N

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

3. Were any cranial sonograms done within 28 days of birth? Y

   If NO, Go to Question D5

   a. If Yes, Were all studies without evidence of intracranial hemorrhage, peri-ventricular leukomalacia or ventriculomegaly? N

   If Yes, Go to Question D5

   b. Date of sonogram for most severe findings: (b) (6)
   Month Day Year

   c. Blood/echodensity in germinal matrix/subependymal area? Y

	(1) RIGHT	(2) LEFT
d. Blood/echodensity in the ventricle?	Y	Y
e. Ventricular size enlarged with concurrent or prior blood in the ventricles?	Y	Y
f. Ventricular size enlarged without concurrent or prior blood in the ventricles?	Y	Y
g. Blood/echo-density in the parenchyma?	N	N

4. Cystic area(s) in the parenchyma within 28 days? N

   If YES,

	(1) RIGHT	(2) LEFT
a. Cystic periventricular leukomalacia within 28 days?		
b. Porencephalic cyst within 28 days?		

5. Were any cranial imaging studies done after 28 days of birth? Y

   If NO, Go to Section E.

6. Cranial sonogram closest to 36 weeks postmenstrual age and after 28 days of birth:

   a. Type of imaging (1=MRI, 2=Sonogram, 3=CT scan) 1

   b. Date of image: (b) (6)
   Month Day Year

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

c. Normal study? N

If NO,

	(1) RIGHT	(2) LEFT
d. Ventricular size enlarged?	N	N
e. Cystic periventricular leukomalacia?	N	N
f. Porencephalic cyst?	N	N

E. INFECTIO

1. Early onset septicemia/bacteremia at (<= 72 hours)? Y
   If YES, organism code(s): a. 200 b.
2. Did the infant receive antibiotics for >= 5 days, starting within the first 72 hours? Y
3. Number of episodes of late onset blood culture negative clinical infection (>=72 hours to status) treated with antibiotics for >= 5 days: 02
4. Late onset culture positive septicemia/bacteremia (>= 72 hours)? N
   If YES,
   a. Number of episodes between day 3 and status that were treated with antibiotics for >= 5 days:
   b. Organism code(s) and date of first positive culture for each of episodes for which the infant was treated with antibiotics for >= 5 days:

a)Episode#	(b) Date	(1) Organism	(2) Organism	(3) Organism
1				
2				
3				
4				
5				
6				

5. Meningitis? N
   a. If YES,

a)Episode#	(b) Date	(1) Organism	(2) Organism	(3) Organism
1				
2				

F. GASTROINTESTINAL

1. Did weight ever fall below the birth weight during the first 10 days? Y
   If YES,
   a. Lowest weight in the first 10 days? 0523
   b. Date of lowest weight in the first 10 days: (b) (6)
   c. Was birth weight regained? Y
   If YES
   d. Date birth weight first regained: (b) (6)

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

2. Did the baby receive patenteral alimentation? Y

   If YES,

   a. Date of first patenteral alimentation [redacted]

   b. Total number of days: 030

3. Did the baby receive enteral feeds? Y

   If YES,

   a. Date of first enteral feed: (b) (6)

   b. Did enteral feeds reach 120 ml/kg/day? Y

      1) If YES, date first achieved: (b) (6)

   c. Did the baby receive breast milk in the first 28 days? Y

      1) If YES, number of days baby received any breast milk in first 28 days: 02

4. Proven NEC: 0

   0 = Absent/Suspect 2 = Proved, no surgery 3 = Proved, surgery

   a. If proven NEC, Date of first episode?

   Month Day Year

5 Spontaneous gastrointestinal perforation without proven NEC? N

   a. If YES, date of the first spontaneous gastrointestinal perforation:

   Month Day Year

6. Did the infant have GI surgery that resulted in short gut? N

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

CENTER: 19 NETWORK: (b) (6) SITENM: (b) (6) Mother's Initials: *** , Birth No: 1

G. HEARING

1. Was a Hearing screen performed? Y

   a. If YES, hearing screen protocol used: 2

   1 = OAE 2 = AABR 3 = ABR 4 = OAE + AABR 5 = Other

   b. Final screen results before discharge

      i) Right ear: 1

      ii) Left ear: 1

      Results: 1. Pass 2. Fail 3. Incomplete

   c. If a failed screen in either ear, was a diagnostic ABR done prior to status?

      1) If YES, answer the following:

         i) Right ear:

         ii) Left ear:

      Results: 1. Pass 2. Fail 3. Incomplete

H. OPHTHALMOLOGY

1. Was an exam performed for ROP? Y

   If Yes,

   a. Was ROP diagnosed in either eye? Y

      If Yes,

      1) Did it reach stage 3 or worse in either eye? Y

      2) Did plus disease develop in either eye? Y

      3) Other therapies

         (if yes, specify):

   b. Intervention Therapies:

      1. Was retinal ablation performed in either eye (laser and/or cryotherapy)? Y

      2. Was any scleral buckle or vitrectomy performed in either eye? N

2. At the time of reaching status, indicate the most appropriate: 3

   1 = Determined, favorable in both eyes

   2 = Determined, severe ROP in either eye

   3 = Undetermined ROP status in either eye (and neither had "severe ROP")

```
1. Determined Favorable:
   -    Vessels mature (fully vascularized)
   -    Vessels in zone III for two consecutive exams
   -    ROP of stage 1 or 2 in zone III for two consecutive exams
   -    ROP in zone II or zone III but determined to be clearly regressing
```

```
2.  Determined-Severe:
    -    ROP surgery
    -    Retinal detachment
    -    Avastin injection
```

```
3.  Undetermined:
    -    Immature Vessels in zone I and II
    -    Immature Vessels reaching zone III for only 1 exam
    -    Stage 1 or 2 ROP in zone III for only 1 exam
    -    Stage 3 ROP in zone III
    -    ROP in zone I or zone II
    -    Plus disease
```

K. 36 WEEK INFORMATION

1. Status at 36 weeks: **2**

1 = Discharged 2 = In hospital 3 = Transferred 5 = Death

If "2", (In Hospital):

a. Date of 36 weeks measurement: (b) (6)
Month Day Year

b. Weight (g) **1239**

c. Length (cm): **38.0**

d. Head circumference (cm) **28.7**

L. FEEDING STATUS:

1. Type of nutrition at discharge to home. Code all that apply

(Do not complete for transfer patients):

1 = Breastmilk 2 = Formula 3 = TPN

2. If enteral, Mode:

1 = Breast 2 = Bottle 3 = NG/NJ tube 4 = Gastrostomy tube 9 = Unknown

M. TRANSFER

Complete this section if status (AI) of infant at time of completion of this form is "3" or "4".

1. Date of transfer:
Month Day Year

2. Final outcome:

1 = Died in Hospital 2 = Discharged to Home 6 = Remains in hospital at one year

a. If discharged to home, final weight at discharge (grams):

N. DISCHARGE ALIVE

Complete this section if status (Q. A1 above) of infant at time of completion of this form is "1" or if the final outcome for a transferred infant is 'Discharged to home.'

1. Date of discharge to home:
Month Day Year

2. Discharged home on continuous oxygen?

3. Discharged home on any of the following medications?

If YES,

a. Diuretics?

b. Bronchodilators?

c. Anticonvulsants?

d. Antireflux medications?

O. DEATH

1. Date of Death:
Month Day Year

a. Time of Death
Hours Minutes

2. Autopsy performed?

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

CENTER: 19 NETWORK: (b) (6) SITENM: (b) Mother's Initials: *** , Birth No: 1

3. Contributory Cause of death

```
Malformation                                          NEC
10 = Congenital malformation                            40 = NEC
Pulmonary                                               41 = NEC with sepsis
20 = RDS                                              CNS Insult
21 = RDS with severe intracranial hemorrhage            50 = Severe intracranial
hemorrhage
22 = RDS with infection                               Other
25 = BPD                                                60 = Immaturity
26 = BPD with infection                                 90 = Other
27 = BPD with severe CNS insult                         99 = Unknown
Infection
30 = Suspect sepsis/infection
31 = Proven sepsis/infection
```

4. If contributory cause of death is code "10" (Congenital malformation), or code "90" (other), specify:

5. Was respiratory support withheld or withdrawn at any time prior to death?
