3. Infant does not have known major congenital malformations? **Y**

If any of above questions are answered 'N' infant is NOT eligible.

B. EXCLUSION CRITERIA

1. The infant was born during a time when the research apparatus/study personnel are not available? **N**

   If Yes, indicate reason:

   1 = Equipment not available 2 = Personnel not available

C. CONSENT

1. Consent Status: **1**

   0 = Not eligible
   1 = Consent granted
   2 = Parent unavailable
   3 = Parent refused consent
   4 = Consent not requested
   5 = Physician refused consent

   a. If parent refused consent (3), consent not requested (4) or physician refused consent (5), indicate reason:

D. RANDOMIZATION

1. Was infant randomized into the study? **Y**

   If No, indicate reason(s):

   If Yes,

   a. Date: (b) (6)
   Month Day Year

   b. Time: **11:30**
   Hour Min

   c. Randomization Number (b) (6)

   d. Treatment Assignment **2**

   1= Early Extubation and CPAP 2= Early Surfactant and Ventilation

   e. Oximeter Color Code: **1**

   1= Blue 2= Orange

Initials of person completing this form: **MLD**

SUPP02 Form Completion Date: **08/12/2008**

CENTER: 19 NETWORK: (b) (6) SITENM: [redacted] Mother's Initials: , Birth No: 1

A. DELIVERY ROOM INFORMATION

1. Date and time of delivery:

   a. Date: (b) (6) (Month Day Year) b. Time: 11:52 (Hour Min)

2. Was CPAP initiated in the DR? N

   If Yes, Date and time of CPAP initiation:

   a. Date: (Month Day Year) b. Time: (Hour Min)

   c. Device:

   1 = Neopuff 2 = Ventilator 3 = Anesthesia Bag 4 = Bubble 9 = Other

   If (9) Other (specify device)

3. Was positive pressure ventilation (PPV) initiated in the DR? Y

4. Was positive and expiratory pressure (PEEP) used in the DR? Y

   If Yes,

   a. Maximum PEEP: 05

5. Was intubation attempted in the DR? Y

   If Yes, was the intubation successful? Y

6. Indication for intubation: 4

   1=Surfactant administration 2=Resuscitation 3= Other (Specify) 4 = As required by randomization assignment

   If (2) Resuscitation,

   a. Low HR?

   b. Poor color?

   c. Apnea?

   d. Other?

   If Other specify:

   If (3) Other, specify:

7. Did the infant receive surfactant in the DR? Y

   If Yes, Date and time of administration:

   a. Date: (b) (6) (Month Day Year) b. Time: 12:10 (Hour Min)

   c. Type: 1

   1 = Infasurf 2 = Curosurf 3 = Survanta 4 = Exosurf 5 = Other (Specify)

   If (5) Other (specify type)

CENTER: 19 NETWORK: (b) (6) SITENM (b) (6) Mother's Initials: , Birth No: 1

A. NICU ADMISSION

1. Date and time of NICU admission

   a. Date: (b) (6) (Month Day Year) b. Time: 12:25 (Hour Min)

2. Respiratory Support on admission to the NICU: 2

   1 = HVF 2 = CV 3 = Nasal SIMV 4 = CPAP 5 = NC 6 = Hood 7 = No Support

3. SaO2: 094

4. FiO2: 0.60

5. Was blood gas done after admission to the NICU? Y

   If Yes, record the first blood gas after admission:

   a. Date: (b) (6) (Month Day Year) b. Time: 12:55 (Hour Min)

   c. Source: 1

   1= Arterial 2= Venous 3= Capillary

   d. pH: 7.30

   e. pCO2: 055

   f. pO2: 120

   g. FiO2: 0.41

6. Date and time the study oximeter was placed on this infant.

   a. Date: (b) (6) (Month Day Year) b. Time: 12:00 (Hour Min)

   c. Serial number: 315452

B. NICU PROCEDURES

1. Was infant intubated for the first time within the first 14 days after admission to the NICU? N

   If Yes,

   a. Date: (Month Day Year) b. Time: (Hour Min)

   c. Indication for intubation:

      1. Surfactant?
      2. FiO2 > .50 to maintain SaO2 >= 88%
      3. pCO2 > 65 on single blood gas?
      4. Apnea requiring bag and mask ventilation?
      5. If NO to all above, state reason:

      1= Hemodynamic instability 2 = Clinical shock/sepsis 3 = Other

      If Other (3), specify

A. MATERNAL INFORMATION

1. Mother's age (years): 26
2. Maternal Zip Code: (b) (6)
3. Pregnancy history (include this pregnancy):
   a. Gravida: 02
   b. Parity: 01
4. Marital Status: 1

1 = Married	2 = Single	6 = Unknown

5. Highest level of education achieved by the Biological Mother: 6

1 = < 7th grade	5 = Partial college
2 = 7th to 9th grade	6 = College degree
3 = 10th to 12th grade	7 = Graduate degree
4 = High School degree	8 = Unknown

6. Mother's medical insurance: 3

1 = Medicaid	6 = Unknown
3 = Private	9 = Other
5 = Self-pay/uninsured	

B. PREGNANCY COMPLICATIONS

1. Multiple birth? N
   a. If YES, Number of fetuses:
2. Mother has evidence of at least one prenatal visit in this pregnancy? Y
3. Diabetes - insulin dependent? N
   If YES, was insulin given prior to pregnancy?
4. Hypertension? N
   a. Hypertension existed prior to pregnancy?
5. Antepartum hemorrhage? N
6. Was Chorioamnionitis documented in the mother's medical record? Y
7. Was a placental pathology performed? Y
   If YES,
   a. Was histologic chorioamnionitis documented? Y

C. LABOR AND DELIVERY

1. Was there a rupture of membranes prior to delivery? N
   If Yes,
   a. Date: Month Day Year
   b. Time: Hour Min
   c. If date and/or time unknown, were ROM estimated at > 18 hours?
2. Were steroids given prior to delivery to accelerate maturity? Y
   a. If YES, Type of antenatal steroid given: 1

1 = Betamethasone	2 = Dexamethasone	3 = Both	4 = UK

   b. Was a complete course of steriods given prior to delivery? Y

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

CENTER: 19 (b) (6) [redacted] SITENM (b) (6) Mother's Initials: *** , Birth No: 1

3. Were maternal antibiotics used during the admission resulting in this delivery? Y

   a. If YES, were antibiotics given within 72 hrs prior to delivery? Y

   1. 01 3. 61 5.
   2. 32 4. 6.

4. Final mode of delivery: 1

1 = Vaginal vertex	2 = Vaginal breech	3 = Cesarean section	4 = Vaginal NOS	5 = Unknown

D. NEONATAL INFORMATION

1. Date and time of birth:

   a. Date: (b) (6) [redacted] (Month Day Year) b. Time: 11:52 (Hour Min)

2. Was the infant outborn? N

   If YES, date and time admitted to NICU:

   a. Date: (Month Day Year)

3. Did the infant die <= 12 hours? N

   IF YES, COMPLETE FORM NG03E

4. Sex: 1

1 = Male	2 = Female	3 = Ambiguous

5. Ethnic Categories: 2

1 = Hispanic or Latino
2 = Not Hispanic or Latino
3 = Unknown or Not Reported

6. Racial Categories: 2

1 = Black	5 = Native Hawaiian or Other Pacific Islander
2 = White	6 = More Than One Race
3 = American Indian or Alaska Native	7 = Unknown or Not Reported
4 = Asian	

   a. If coding option 6, record all races indicated (optional)

7. Gestational age: a. Weeks: 25 b. Days: 5
8. Apgar score - 1 minute: 03
9. Apgar score - 5 minutes: 09
10. Birth resuscitation/stabilization:
    a. Oxygen? Y
    b. Bagging and mask? Y
    c. CPAP? N
    d. Intubation? Y
    e. Chest compression? N
    f. Epinephrine? N

A. STATUS

1. Status of infant at time of completion of form: 3

1 = Discharged to home	4 = Transferred to chronic care facility
2 = Still in hospital at 120 days	5 = Death
3 = Transferred to another hospital	

2. Date of status: (b) (6) (Month Day Year)
3. Weight at status (grams): 1636
4. Length at status (cm): 43.0
5. Head circumference at status (cm): 29.5

B. PULMONARY

1. Respiratory distress:
   a. Demonstrated clinical features of respiratory distress within the first 24 hrs? Y
   b. Required oxygen or postive pressure for more than 6 hours within the first 24 hours? Y
2. Did the baby receive surfactants? Y
   a. If YES, date and time of first dose: (b) (6) (Month Day Year) 12:10 (Hours Min)
   b. Total number of surfactant doses: 001
3. Pneumothorax? N
4. Pulmonary hemorrhage? N
5. Steroids for BPD/CLD? N
   a. If YES, Date of first dose: (Month Day Year)
6. Did infant receive inhaled nitric oxide? N
   a. If YES, Date of first exposure:

C. CARDIAC

1. Patent ductus arteriosus (PDA)? Y
   If YES, treatment:
   a. Indomethacin? N
   If YES, total number of courses
   b. Ibuprofin N
   If YES, total number of courses
   c. Surgery? Y

D. NEUROLOGIC

1. Was indomethacin given within the first 24 hrs for any prophylaxis? N
   If YES,
   a. Date: (Month Day Year) b. Time: (Hour Min)
2. Were there seizures treated with an anti-convulsant for >72 hours? N

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

3. Were any cranial sonograms done within 28 days of birth? Y

   If NO, Go to Question D5

   a. If Yes, Were all studies without evidence of intracranial hemorrhage, peri-ventricular leukomalacia or ventriculomegaly? Y

   If Yes, Go to Question D5

   b. Date of sonogram for most severe findings:
   Month Day Year

   c. Blood/echodensity in germinal matrix/subependymal area?

	(1) RIGHT	(2) LEFT
d. Blood/echodensity in the ventricle?		
e. Ventricular size enlarged with concurrent or prior blood in the ventricles?		
f. Ventricular size enlarged without concurrent or prior blood in the ventricles?		
g. Blood/echo-density in the parenchyma?		

4. Cystic area(s) in the parenchyma within 28 days?

   If YES,

	(1) RIGHT	(2) LEFT
a. Cystic periventricular leukomalacia within 28 days?		
b. Porencephalic cyst within 28 days?		

5. Were any cranial imaging studies done after 28 days of birth? Y

   If NO, Go to Section E.

6. Cranial sonogram closest to 36 weeks postmenstrual age and after 28 days of birth:

   a. Type of imaging (1=MRI, 2=Sonogram, 3=CT scan) 1

   b. Date of image: (b) (6)
   Month Day Year

c. Normal study? Y

If NO,

	(1) RIGHT	(2) LEFT
d. Ventricular size enlarged?		
e. Cystic periventricular leukomalacia?		
f. Porencephalic cyst?		

E. INFECTIO

1. Early onset septicemia/bacteremia at (<= 72 hours)? N
   If YES, organism code(s): a. b.
2. Did the infant receive antibiotics for >= 5 days, starting within the first 72 hours? Y
3. Number of episodes of late onset blood culture negative clinical infection (>=72 hours to status) treated with antibiotics for >= 5 days: 00
4. Late onset culture positive septicemia/bacteremia (>= 72 hours)? N
   If YES,
   a. Number of episodes between day 3 and status that were treated with antibiotics for >= 5 days:
   b. Organism code(s) and date of first positive culture for each of episodes for which the infant was treated with antibiotics for >= 5 days:

a)Episode#	(b) Date	(1) Organism	(2) Organism	(3) Organism
1				
2				
3				
4				
5				
6				

5. Meningitis? N
   a. If YES,

a)Episode#	(b) Date	(1) Organism	(2) Organism	(3) Organism
1				
2				

F. GASTROINTESTINAL

1. Did weight ever fall below the birth weight during the first 10 days? Y
   If YES,
   a. Lowest weight in the first 10 days? 0795
   b. Date of lowest weight in the first 10 days: [redacted]
   c. Was birth weight regained? Y
   If YES
   d. Date birth weight first regained: (b) (6) [redacted]

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

2. Did the baby receive patenteral alimentation? Y

   If YES,

   a. Date of first patenteral alimentation (b) (6)

   b. Total number of days: 019

3. Did the baby receive enteral feeds? Y

   If YES,

   a. Date of first enteral feed: (b) (6)

   b. Did enteral feeds reach 120 ml/kg/day? Y

      1) If YES, date first achieved: (b) (6)

   c. Did the baby receive breast milk in the first 28 days? Y

      1) If YES, number of days baby received any breast milk in first 28 days: 21

4. Proven NEC: 0

   0 = Absent/Suspect 2 = Proved, no surgery 3 = Proved, surgery

   a. If proven NEC, Date of first episode?

      Month Day Year

5 Spontaneous gastrointestinal perforation without proven NEC? N

   a. If YES, date of the first spontaneous gastrointestinal perforation:

      Month Day Year

6. Did the infant have GI surgery that resulted in short gut? N

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

CENTER: 19 NETWORK: (b) (6) SITENM (b) (6) Mother's Initials: *** , Birth No: 1

G. HEARING

1. Was a Hearing screen performed? **N**

   a. If YES, hearing screen protocol used:

   1 = OAE 2 = AABR 3 = ABR 4 = OAE + AABR 5 = Other

   b. Final screen results before discharge

      i) Right ear:

      ii) Left ear:

      Results: 1. Pass 2. Fail 3. Incomplete

   c. If a failed screen in either ear, was a diagnostic ABR done prior to status?

      1) If YES, answer the following:

         i) Right ear:

         ii) Left ear:

      Results: 1. Pass 2. Fail 3. Incomplete

H. OPHTHALMOLOGY

1. Was an exam performed for ROP? **Y**

   If Yes,

   a. Was ROP diagnosed in either eye? **Y**

      If Yes,

      1) Did it reach stage 3 or worse in either eye? **N**

      2) Did plus disease develop in either eye? **N**

      3) Other therapies

         (if yes, specify):

   b. Intervention Therapies:

      1. Was retinal ablation performed in either eye (laser and/or cryotherapy)? **N**

      2. Was any scleral buckle or vitrectomy performed in either eye? **N**

2. At the time of reaching status, indicate the most appropriate: **3**

   1 = Determined, favorable in both eyes

   2 = Determined, severe ROP in either eye

   3 = Undetermined ROP status in either eye (and neither had "severe ROP")

1. Determined Favorable:
   - Vessels mature (fully vascularized)
   - Vessels in zone III for two consecutive exams
   - ROP of stage 1 or 2 in zone III for two consecutive exams
   - ROP in zone II or zone III but determined to be clearly regressing

2. Determined-Severe:
   - ROP surgery
   - Retinal detachment
   - Avastin injection

3. Undetermined:
   - Immature Vessels in zone I and II
   - Immature Vessels reaching zone III for only 1 exam
   - Stage 1 or 2 ROP in zone III for only 1 exam
   - Stage 3 ROP in zone III
   - ROP in zone I or zone II
   - Plus disease

a. If discharged to home, final weight at discharge (grams): **2645**

N. DISCHARGE ALIVE

Complete this section if status (Q. A1 above) of infant at time of completion of this form is "1" or if the final outcome for a transferred infant is 'Discharged to home.'

1. Date of discharge to home: (b)
Month Day Year

2. Discharged home on continuous oxygen? **N**

3. Discharged home on any of the following medications? **N**

If YES,

a. Diuretics?

b. Bronchodilators?

c. Anticonvulsants?

d. Antireflux medications?

O. DEATH

1. Date of Death:
Month Day Year

a. Time of Death
Hours Minutes

2. Autopsy performed?

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

CENTER: 19 NETWORK: (b) (6) SITENM (b) Mother's Initials: *** , Birth No: 1

3. Contributory Cause of death

```
Malformation                                        NEC
10 = Congenital malformation                          40 = NEC
Pulmonary                                             41 = NEC with sepsis
20 = RDS                                            CNS Insult
21 = RDS with severe intracranial hemorrhage          50 = Severe intracranial
hemorrhage                                          Other
22 = RDS with infection                               60 = Immaturity
25 = BPD                                              90 = Other
26 = BPD with infection                               99 = Unknown
27 = BPD with severe CNS insult
Infection
30 = Suspect sepsis/infection
31 = Proven sepsis/infection
```

4. If contributory cause of death is code "10" (Congenital malformation), or code "90" (other), specify:

5. Was respiratory support withheld or withdrawn at any time prior to death?

Initials of person completing this form: MLD

A. SNAPSHOT	@ 24 HOUR	@ 36 WEEKS	B. CUMULATIVE DATA	DAY 3	DAY 7	DAY 14	DAY 28	36 WEEK	STATUS
1. On HFV?	N		1. Number days on HFV	0	0	00	00		000
2. On CV?	Y		2. Number of days on CV	2	2	07	10		013
3. On nasal SIMV?	N		3. Number of days on nasal SIMV	0	2	02	02		014
4. On CPAP	N		4. Number days on CPAP	1	3	05	16		026
			5. Number of days on supplemental O2	3	7	14	28		054
6. FiO2	0.21		6. Highest FIO2 on day	0.23	0.21	0.40	0.26		0.23
OR			OR						
7. Supplemental O2 by nasal cannula?			7. Supplemental O2 by nasal cannula?						
8. If FiO2 = .21 (#6), by nasal cannula.	Y		8. If FiO2 = .21 (#6), by nasal cannula, CPAP or vent?		Y				

If in section 'A', snapshot @36 weeks, questions 1-4 are answered NO and either question 6 FiO2 > 0.21 or questions 7 or 8 are answered YES, complete section C :

C. Physiologic Evaluation

1. Is the infant eligible for the physiologic evaluation?

IF YES to question C.1

a. Was the evaluation performed?

b. Date of evaluation

Month Day Year

c. Actual FIO2 being delivered at time of challenge. For infants receiving blended supplemental oxygen via nasal cannula, record the blend in this field

d. If on nasal cannula at time of challenge, record flow rate

e. Did the patient pass the evaluation?

IF NO to question C.1.a

f. If patient was eligible and evaluation not done, code reason:

If 9, explain

```
1= Increased FIO2                                4= Parent/Physicial Refusal
2= Increased respiratory support (cpap or vent)  6= Weaned to room air on/before day of evaluation
3= Instability (including Surgery/Sepsis)        9= Other-explain
```

This form should be completed for all inborn infants with a gestational age of 24 0/7 to 27 6/7 weeks gestation by best obstetrical estimates and who are to receive full resuscitation.

A. INCLUSION CRITERIA

1. Inborn infant with a minimal gestational age of 24 weeks 0 days to 27 6/7 completed weeks by best obstetrical estimate? **Y**
2. Infant to receive full resuscitation as necessary? **Y**
3. Infant does not have known major congenital malformations? **Y**

If any of above questions are answered 'N' infant is NOT eligible.

B. EXCLUSION CRITERIA

1. The infant was born during a time when the research apparatus/study personnel are not available? **N**

   If Yes, indicate reason:

   1 = Equipment not available 2 = Personnel not available

C. CONSENT

1. Consent Status: **1**

   0 = Not eligible
   1 = Consent granted
   2 = Parent unavailable
   3 = Parent refused consent
   4 = Consent not requested
   5 = Physician refused consent

   a. If parent refused consent (3), consent not requested (4) or physician refused consent (5), indicate reason:

D. RANDOMIZATION

1. Was infant randomized into the study? **Y**

   If No, indicate reason(s):

   If Yes,

   a. Date: (b) (6)
   Month Day Year

   b. Time: **16:00**
   Hour Min

   c. Randomization Number (b) (6)

   d. Treatment Assignment **1**

   1= Early Extubation and CPAP 2= Early Surfactant and Ventilation

   e. Oximeter Color Code: **1**

   1= Blue 2= Orange

Initials of person completing this form: **MLD**

A. DELIVERY ROOM INFORMATION

1. Date and time of delivery:

   a. Date: (b) (6) (Month Day Year) b. Time: 16:32 (Hour Min)

2. Was CPAP initiated in the DR? Y

   If Yes, Date and time of CPAP initiation:

   a. Date: (b) (6) (Month Day Year) b. Time: 16:33 (Hour Min)

   c. Device: 1

   1 = Neopuff 2 = Ventilator 3 = Anesthesia Bag 4 = Bubble 9 = Other

   If (9) Other (specify device)

3. Was positive pressure ventilation (PPV) initiated in the DR? Y

4. Was positive and expiratory pressure (PEEP) used in the DR? Y

   If Yes,

   a. Maximum PEEP: 05

5. Was intubation attempted in the DR? Y

   If Yes, was the intubation successful? Y

6. Indication for intubation: 2

   1=Surfactant administration 2=Resuscitation 3= Other (Specify) 4 = As required by randomization assignment

   If (2) Resuscitation,

   a. Low HR? N

   b. Poor color? Y

   c. Apnea? Y

   d. Other? N

   If Other specify:

   If (3) Other, specify:

7. Did the infant receive surfactant in the DR? Y

   If Yes, Date and time of administration:

   a. Date: (b) (6) (Month Day Year) b. Time: 16:45 (Hour Min)

   c. Type: 1

   1 = Infasurf 2 = Curosurf 3 = Survanta 4 = Exosurf 5 = Other (Specify)

   If (5) Other (specify type)

3. Pregnancy history (include this pregnancy):
   a. Gravida: 03
   b. Parity: 03
4. Marital Status: 1

1 = Married	2 = Single	6 = Unknown

5. Highest level of education achieved by the Biological Mother: 6

1 = < 7th grade	5 = Partial college
2 = 7th to 9th grade	6 = College degree
3 = 10th to 12th grade	7 = Graduate degree
4 = High School degree	8 = Unknown

6. Mother's medical insurance: 3

1 = Medicaid	6 = Unknown
3 = Private	9 = Other
5 = Self-pay/uninsured	

B. PREGNANCY COMPLICATIONS

1. Multiple birth? Y
   a. If YES, Number of fetuses: 2
2. Mother has evidence of at least one prenatal visit in this pregnancy? Y
3. Diabetes - insulin dependent? N
   If YES, was insulin given prior to pregnancy?
4. Hypertension? N
   a. Hypertension existed prior to pregnancy?
5. Antepartum hemorrhage? N
6. Was Chorioamnionitis documented in the mother's medical record? N
7. Was a placental pathology performed? Y
   If YES,
   a. Was histologic chorioamnionitis documented? N

C. LABOR AND DELIVERY

1. Was there a rupture of membranes prior to delivery? N
   If Yes,
   a. Date: Month Day Year
   b. Time: Hour Min
   c. If date and/or time unknown, were ROM estimated at > 18 hours?
2. Were steroids given prior to delivery to accelerate maturity? Y
   a. If YES, Type of antenatal steroid given: 1

1 = Betamethasone	2 = Dexamethasone	3 = Both	4 = UK

   b. Was a complete course of steriods given prior to delivery? Y

   b. Required oxygen or postive pressure for more than 6 hours within the first 24 hours? Y
2. Did the baby receive surfactants? Y
   a. If YES, date and time of first dose: (b) (6) [redacted] (Month Day Year) 16:45 (Hours Min)
   b. Total number of surfactant doses: 002
3. Pneumothorax? N
4. Pulmonary hemorrhage? N
5. Steroids for BPD/CLD? N
   a. If YES, Date of first dose: [redacted] (Month Day Year)
6. Did infant receive inhaled nitric oxide? N
   a. If YES, Date of first exposure: [redacted]

C. CARDIAC

1. Patent ductus arteriosus (PDA)? Y
   If YES, treatment:
   a. Indomethacin? N
   If YES, total number of courses
   b. Ibuprofin Y
   If YES, total number of courses 03
   c. Surgery? N

D. NEUROLOGIC

1. Was indomethacin given within the first 24 hrs for any prophylaxis? Y
   If YES,
   a. Date: (b) (6) [redacted] (Month Day Year) b. Time: 17:19 (Hour Min)
2. Were there seizures treated with an anti-convulsant for >72 hours? N

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

3. Were any cranial sonograms done within 28 days of birth? **Y**

   If NO, Go to Question D5

   a. If Yes, Were all studies without evidence of intracranial hemorrhage, peri-ventricular leukomalacia or ventriculomegaly? **N**

   If Yes, Go to Question D5

   b. Date of sonogram for most severe findings: (b) (6)
   Month Day Year

   c. Blood/echodensity in germinal matrix/subependymal area? **N**

	(1) RIGHT	(2) LEFT
d. Blood/echodensity in the ventricle?	N	N
e. Ventricular size enlarged with concurrent or prior blood in the ventricles?	N	N
f. Ventricular size enlarged without concurrent or prior blood in the ventricles?	N	N
g. Blood/echo-density in the parenchyma?	N	N

4. Cystic area(s) in the parenchyma within 28 days? **N**

   If YES,

	(1) RIGHT	(2) LEFT
a. Cystic periventricular leukomalacia within 28 days?		
b. Porencephalic cyst within 28 days?		

5. Were any cranial imaging studies done after 28 days of birth? **Y**

   If NO, Go to Section E.

6. Cranial sonogram closest to 36 weeks postmenstrual age and after 28 days of birth:

   a. Type of imaging (1=MRI, 2=Sonogram, 3=CT scan) **2**

   b. Date of image: (b) (6)
   Month Day Year

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

c. Normal study? Y

If NO,

	(1) RIGHT	(2) LEFT
d. Ventricular size enlarged?		
e. Cystic periventricular leukomalacia?		
f. Porencephalic cyst?		

E. INFECTIO

1. Early onset septicemia/bacteremia at (<= 72 hours)? N
   If YES, organism code(s): a. [redacted] b. [redacted]
2. Did the infant receive antibiotics for >= 5 days, starting within the first 72 hours? Y
3. Number of episodes of late onset blood culture negative clinical infection (>=72 hours to status) treated with antibiotics for >= 5 days: 02
4. Late onset culture positive septicemia/bacteremia (>= 72 hours)? N
   If YES,
   a. Number of episodes between day 3 and status that were treated with antibiotics for >= 5 days: [redacted]
   b. Organism code(s) and date of first positive culture for each of episodes for which the infant was treated with antibiotics for >= 5 days:

a)Episode#	(b) Date	(1) Organism	(2) Organism	(3) Organism
1	[redacted]	[redacted]	[redacted]	[redacted]
2	[redacted]	[redacted]	[redacted]	[redacted]
3	[redacted]	[redacted]	[redacted]	[redacted]
4	[redacted]	[redacted]	[redacted]	[redacted]
5	[redacted]	[redacted]	[redacted]	[redacted]
6	[redacted]	[redacted]	[redacted]	[redacted]

5. Meningitis? N
   a. If YES,

a)Episode#	(b) Date	(1) Organism	(2) Organism	(3) Organism
1	[redacted]	[redacted]	[redacted]	[redacted]
2	[redacted]	[redacted]	[redacted]	[redacted]

F. GASTROINTESTINAL

1. Did weight ever fall below the birth weight during the first 10 days? Y
   If YES,
   a. Lowest weight in the first 10 days? 0673
   b. Date of lowest weight in the first 10 days: (b) (6) [redacted]
   c. Was birth weight regained? Y
   If YES
   d. Date birth weight first regained: (b) (6) [redacted]

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

2. Did the baby receive patenteral alimentation? **Y**

   If YES,

   a. Date of first patenteral alimentation (b) (6)

   b. Total number of days: **018**

3. Did the baby receive enteral feeds? **Y**

   If YES,

   a. Date of first enteral feed: (b) (6)

   b. Did enteral feeds reach 120 ml/kg/day? **Y**

      1) If YES, date first achieved: [redacted]

   c. Did the baby receive breast milk in the first 28 days? **Y**

      1) If YES, number of days baby received any breast milk in first 28 days: **18**

4. Proven NEC: **0**

   0 = Absent/Suspect 2 = Proved, no surgery 3 = Proved, surgery

   a. If proven NEC, Date of first episode?

   Month Day Year

5 Spontaneous gastrointestinal perforation without proven NEC? **N**

   a. If YES, date of the first spontaneous gastrointestinal perforation:

   Month Day Year

6. Did the infant have GI surgery that resulted in short gut? **N**

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

CENTER: 19 NETWORK: (b) (6) SITENM(b) (6) Mother's Initials: *** , Birth No: 1

G. HEARING

1. Was a Hearing screen performed? **Y**

   a. If YES, hearing screen protocol used: **3**

1 = OAE	2 = AABR	3 = ABR	4 = OAE + AABR	5 = Other

   b. Final screen results before discharge

      i) Right ear: **1**

      ii) Left ear: **1**

Results:	1. Pass	2. Fail	3. Incomplete

   c. If a failed screen in either ear, was a diagnostic ABR done prior to status?

      1) If YES, answer the following:

         i) Right ear:

         ii) Left ear:

Results:	1. Pass	2. Fail	3. Incomplete

H. OPHTHALMOLOGY

1. Was an exam performed for ROP? **Y**

   If Yes,

   a. Was ROP diagnosed in either eye? **Y**

      If Yes,

      1) Did it reach stage 3 or worse in either eye? **Y**

      2) Did plus disease develop in either eye? **N**

      3) Other therapies **N**

         (if yes, specify):

   b. Intervention Therapies:

      1. Was retinal ablation performed in either eye (laser and/or cryotherapy)? **Y**

      2. Was any scleral buckle or vitrectomy performed in either eye? **N**

2. At the time of reaching status, indicate the most appropriate: **1**

   1 = Determined, favorable in both eyes

   2 = Determined, severe ROP in either eye

   3 = Undetermined ROP status in either eye (and neither had "severe ROP")

1. Determined Favorable:
   - Vessels mature (fully vascularized)
   - Vessels in zone III for two consecutive exams
   - ROP of stage 1 or 2 in zone III for two consecutive exams
   - ROP in zone II or zone III but determined to be clearly regressing

2. Determined-Severe:
   - ROP surgery
   - Retinal detachment
   - Avastin injection

3. Undetermined:
   - Immature Vessels in zone I and II
   - Immature Vessels reaching zone III for only 1 exam
   - Stage 1 or 2 ROP in zone III for only 1 exam
   - Stage 3 ROP in zone III
   - ROP in zone I or zone II
   - Plus disease

K. 36 WEEK INFORMATION

1. Status at 36 weeks: **2**

1 = Discharged 2 = In hospital 3 = Transferred 5 = Death

If "2", (In Hospital):

a. Date of 36 weeks measurement: (b) (6)
Month Day Year

b. Weight (g) **1407**

c. Length (cm): **.*

d. Head circumference (cm) **.*

L. FEEDING STATUS:

1. Type of nutrition at discharge to home. Code all that apply **1** **2**

(Do not complete for transfer patients):

1 = Breastmilk 2 = Formula 3 = TPN

2. If enteral, Mode: **1** **2**

1 = Breast 2 = Bottle 3 = NG/NJ tube 4 = Gastrostomy tube 9 = Unknown

M. TRANSFER

Complete this section if status (AI) of infant at time of completion of this form is "3" or "4".

1. Date of transfer:
Month Day Year

2. Final outcome:

1 = Died in Hospital 2 = Discharged to Home 6 = Remains in hospital at one year

a. If discharged to home, final weight at discharge (grams):

N. DISCHARGE ALIVE

Complete this section if status (Q. A1 above) of infant at time of completion of this form is "1" or if the final outcome for a transferred infant is 'Discharged to home.'

1. Date of discharge to home: (b) (6)
Month Day Year

2. Discharged home on continuous oxygen? **N**

3. Discharged home on any of the following medications? **Y**

If YES,

a. Diuretics? **N**

b. Bronchodilators? **N**

c. Anticonvulsants? **N**

d. Antireflux medications? **Y**

O. DEATH

1. Date of Death:
Month Day Year

a. Time of Death
Hours Minutes

2. Autopsy performed?

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

This form should be completed for all inborn infants with a gestational age of 24 0/7 to 27 6/7 weeks gestation by best obstetrical estimates and who are to receive full resuscitation.

A. INCLUSION CRITERIA

1. Inborn infant with a minimal gestational age of 24 weeks 0 days to 27 6/7 completed weeks by best obstetrical estimate? **Y**
2. Infant to receive full resuscitation as necessary? **Y**
3. Infant does not have known major congenital malformations? **Y**

If any of above questions are answered 'N' infant is NOT eligible.

B. EXCLUSION CRITERIA

1. The infant was born during a time when the research apparatus/study personnel are not available? **N**

   If Yes, indicate reason:

   1 = Equipment not available 2 = Personnel not available

C. CONSENT

1. Consent Status: **1**

   0 = Not eligible
   1 = Consent granted
   2 = Parent unavailable
   3 = Parent refused consent
   4 = Consent not requested
   5 = Physician refused consent

   a. If parent refused consent (3), consent not requested (4) or physician refused consent (5), indicate reason:

D. RANDOMIZATION

1. Was infant randomized into the study? **Y**

   If No, indicate reason(s):

   If Yes,

   a. Date: (b) (6)
   Month Day Year

   b. Time: **04:23**
   Hour Min

   c. Randomization Number (b) (6)

   a. Demonstrated clinical features of respiratory distress within the first 24 hrs? Y
   b. Required oxygen or postive pressure for more than 6 hours within the first 24 hours? Y
2. Did the baby receive surfactants? Y
   a. If YES, date and time of first dose: (b) (6) Month Day Year **:** Hours Min
   b. Total number of surfactant doses: 003
3. Pneumothorax? Y
4. Pulmonary hemorrhage? N
5. Steroids for BPD/CLD? Y
   a. If YES, Date of first dose: (b) (6) Month Day Year
6. Did infant receive inhaled nitric oxide? Y
   a. If YES, Date of first exposure: (b) (6)

C. CARDIAC

1. Patent ductus arteriosus (PDA)? N
   If YES, treatment:
   a. Indomethacin?
   If YES, total number of courses
   b. Ibuprofin
   If YES, total number of courses
   c. Surgery?

D. NEUROLOGIC

1. Was indomethacin given within the first 24 hrs for any prophylaxis? N
   If YES,
   a. Date: Month Day Year b. Time: Hour Min
2. Were there seizures treated with an anti-convulsant for >72 hours? N

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

3. Were any cranial sonograms done within 28 days of birth? Y

   If NO, Go to Question D5

   a. If Yes, Were all studies without evidence of intracranial hemorrhage, peri-ventricular leukomalacia or ventriculomegaly? Y

   If Yes, Go to Question D5

   b. Date of sonogram for most severe findings:
   Month Day Year

   c. Blood/echodensity in germinal matrix/subependymal area?

	(1) RIGHT	(2) LEFT
d. Blood/echodensity in the ventricle?		
e. Ventricular size enlarged with concurrent or prior blood in the ventricles?		
f. Ventricular size enlarged without concurrent or prior blood in the ventricles?		
g. Blood/echo-density in the parenchyma?		

4. Cystic area(s) in the parenchyma within 28 days?

   If YES,

	(1) RIGHT	(2) LEFT
a. Cystic periventricular leukomalacia within 28 days?		
b. Porencephalic cyst within 28 days?		

5. Were any cranial imaging studies done after 28 days of birth? Y

   If NO, Go to Section E.

6. Cranial sonogram closest to 36 weeks postmenstrual age and after 28 days of birth:

   a. Type of imaging (1=MRI, 2=Sonogram, 3=CT scan) 2

   b. Date of image: (b) (6)
   Month Day Year

CENTER: 19 NETWORK: (b) (6) SITENM: Mother's Initials: , Birth No: 1

c. Normal study? Y

If NO,

	(1) RIGHT	(2) LEFT
d. Ventricular size enlarged?		
e. Cystic periventricular leukomalacia?		
f. Porencephalic cyst?		

E. INFECTIO

1. Early onset septicemia/bacteremia at (<= 72 hours)? N
   If YES, organism code(s): a. b.
2. Did the infant receive antibiotics for >= 5 days, starting within the first 72 hours? Y
3. Number of episodes of late onset blood culture negative clinical infection (>=72 hours to status) treated with antibiotics for >= 5 days: 06
4. Late onset culture positive septicemia/bacteremia (>= 72 hours)? Y
   If YES,
   a. Number of episodes between day 3 and status that were treated with antibiotics for >= 5 days: 00
   b. Organism code(s) and date of first positive culture for each of episodes for which the infant was treated with antibiotics for >= 5 days:

a)Episode#	(b) Date	(1) Organism	(2) Organism	(3) Organism
1				
2				
3				
4				
5				
6				

5. Meningitis? N
   a. If YES,

a)Episode#	(b) Date	(1) Organism	(2) Organism	(3) Organism
1				
2				

F. GASTROINTESTINAL

1. Did weight ever fall below the birth weight during the first 10 days? Y
   If YES,
   a. Lowest weight in the first 10 days? 0651
   b. Date of lowest weight in the first 10 days: (b)
   c. Was birth weight regained? Y
   If YES
   d. Date birth weight first regained: (b) (6)

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

CENTER: 19 NETWORK: (b) (6) SITENM: (b) Mother's Initials: , Birth No: 1

2. Did the baby receive patenteral alimentation? Y

If YES,

a. Date of first patenteral alimentation (b) (6)

b. Total number of days: 031

3. Did the baby receive enteral feeds? Y

If YES,

a. Date of first enteral feed: (b) (6)

b. Did enteral feeds reach 120 ml/kg/day? Y

1) If YES, date first achieved: (b) (6)

c. Did the baby receive breast milk in the first 28 days? Y

1) If YES, number of days baby received any breast milk in first 28 days: 02

4. Proven NEC: 0

0 = Absent/Suspect 2 = Proved, no surgery 3 = Proved, surgery

a. If proven NEC, Date of first episode?

Month Day Year

5 Spontaneous gastrointestinal perforation without proven NEC? N

a. If YES, date of the first spontaneous gastrointestinal perforation:

Month Day Year

6. Did the infant have GI surgery that resulted in short gut? N

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

G. HEARING

1. Was a Hearing screen performed? Y

   a. If YES, hearing screen protocol used: 3

   1 = OAE 2 = AABR 3 = ABR 4 = OAE + AABR 5 = Other

   b. Final screen results before discharge

      i) Right ear: 1

      ii) Left ear: 1

      Results: 1. Pass 2. Fail 3. Incomplete

   c. If a failed screen in either ear, was a diagnostic ABR done prior to status?

      1) If YES, answer the following:

         i) Right ear:

         ii) Left ear:

      Results: 1. Pass 2. Fail 3. Incomplete

H. OPHTHALMOLOGY

1. Was an exam performed for ROP? Y

   If Yes,

   a. Was ROP diagnosed in either eye? Y

      If Yes,

      1) Did it reach stage 3 or worse in either eye? Y

      2) Did plus disease develop in either eye? Y

      3) Other therapies N

         (if yes, specify):

   b. Intervention Therapies:

      1. Was retinal ablation performed in either eye (laser and/or cryotherapy)? Y

      2. Was any scleral buckle or vitrectomy performed in either eye? N

2. At the time of reaching status, indicate the most appropriate: 1

   1 = Determined, favorable in both eyes

   2 = Determined, severe ROP in either eye

   3 = Undetermined ROP status in either eye (and neither had "severe ROP")

1. Determined Favorable:
   - Vessels mature (fully vascularized)
   - Vessels in zone III for two consecutive exams
   - ROP of stage 1 or 2 in zone III for two consecutive exams
   - ROP in zone II or zone III but determined to be clearly regressing

2. Determined-Severe:
   - ROP surgery
   - Retinal detachment
   - Avastin injection

3. Undetermined:
   - Immature Vessels in zone I and II
   - Immature Vessels reaching zone III for only 1 exam
   - Stage 1 or 2 ROP in zone III for only 1 exam
   - Stage 3 ROP in zone III
   - ROP in zone I or zone II
   - Plus disease

K. 36 WEEK INFORMATION

1. Status at 36 weeks: **2**

1 = Discharged 2 = In hospital 3 = Transferred 5 = Death

If "2", (In Hospital):

a. Date of 36 weeks measurement: (b) (6)
Month Day Year

b. Weight (g) **0885**

c. Length (cm): ****.***

d. Head circumference (cm) ****.***

L. FEEDING STATUS:

1. Type of nutrition at discharge to home. Code all that apply

(Do not complete for transfer patients):

1 = Breastmilk 2 = Formula 3 = TPN

2. If enteral, Mode:

1 = Breast 2 = Bottle 3 = NG/NJ tube 4 = Gastrostomy tube 9 = Unknown

M. TRANSFER

Complete this section if status (AI) of infant at time of completion of this form is "3" or "4".

1. Date of transfer:
Month Day Year

2. Final outcome:

1 = Died in Hospital 2 = Discharged to Home 6 = Remains in hospital at one year

a. If discharged to home, final weight at discharge (grams):

N. DISCHARGE ALIVE

Complete this section if status (Q. A1 above) of infant at time of completion of this form is "1" or if the final outcome for a transferred infant is 'Discharged to home.'

1. Date of discharge to home:
Month Day Year

2. Discharged home on continuous oxygen?

3. Discharged home on any of the following medications?

If YES,

a. Diuretics?

b. Bronchodilators?

c. Anticonvulsants?

d. Antireflux medications?

O. DEATH

1. Date of Death:
Month Day Year

a. Time of Death
Hours Minutes

2. Autopsy performed?

A. MATERNAL INFORMATION

1. Mother's age (years): 26
2. Maternal Zip Code: (b) (6)
3. Pregnancy history (include this pregnancy): (6)
   a. Gravida: 02
   b. Parity: 01
4. Marital Status: 1

1 = Married	2 = Single	6 = Unknown

5. Highest level of education achieved by the Biological Mother: 6

1 = < 7th grade	5 = Partial college
2 = 7th to 9th grade	6 = College degree
3 = 10th to 12th grade	7 = Graduate degree
4 = High School degree	8 = Unknown

6. Mother's medical insurance: 3

1 = Medicaid	6 = Unknown
3 = Private	9 = Other
5 = Self-pay/uninsured	

B. PREGNANCY COMPLICATIONS

1. Multiple birth? N
   a. If YES, Number of fetuses:
2. Mother has evidence of at least one prenatal visit in this pregnancy? Y
3. Diabetes - insulin dependent? N
   If YES, was insulin given prior to pregnancy?
4. Hypertension? N
   a. Hypertension existed prior to pregnancy?
5. Antepartum hemorrhage? N
6. Was Chorioamnionitis documented in the mother's medical record? Y
7. Was a placental pathology performed? Y
   If YES,
   a. Was histologic chorioamnionitis documented? Y

C. LABOR AND DELIVERY

1. Was there a rupture of membranes prior to delivery? N
   If Yes,
   a. Date: Month Day Year
   b. Time: Hour Min
   c. If date and/or time unknown, were ROM estimated at > 18 hours?
2. Were steroids given prior to delivery to accelerate maturity? Y
   a. If YES, Type of antenatal steroid given: 1

1 = Betamethasone	2 = Dexamethasone	3 = Both	4 = UK

   b. Was a complete course of steriods given prior to delivery? Y

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

3. Were maternal antibiotics used during the admission resulting in this delivery? Y

a. If YES, were antibiotics given within 72 hrs prior to delivery? U

1. 3. 5.

2. 4. 6.

4. Final mode of delivery: 1

1 = Vaginal vertex	2 = Vaginal breech	3 = Cesarean section	4 = Vaginal NOS	5 = Unknown

D. NEONATAL INFORMATION

1. Date and time of birth:

a. Date: (b) (6) (Month Day Year) b. Time: 04:23 (Hour Min)

2. Was the infant outborn? N

If YES, date and time admitted to NICU:

a. Date: (Month Day Year)

3. Did the infant die <= 12 hours? N

IF YES, COMPLETE FORM NG03E

4. Sex: 1

1 = Male	2 = Female	3 = Ambiguous

5. Ethnic Categories: 2

1 = Hispanic or Latino
2 = Not Hispanic or Latino
3 = Unknown or Not Reported

6. Racial Categories: 2

1 = Black	5 = Native Hawaiian or Other Pacific Islander
2 = White	6 = More Than One Race
3 = American Indian or Alaska Native	7 = Unknown or Not Reported
4 = Asian	

a. If coding option 6, record all races indicated (optional)

7. Gestational age: a. Weeks: 25 b. Days: 1

8. Apgar score - 1 minute: 03

9. Apgar score - 5 minutes: 08

10. Birth resuscitation/stabilization:

a. Oxygen? Y

b. Bagging and mask? N

c. CPAP? Y

d. Intubation? Y

e. Chest compression? N

f. Epinephrine? N

11. Birth Weight (grams): 0770

3. Were any cranial sonograms done within 28 days of birth? Y

   If NO, Go to Question D5

   a. If Yes, Were all studies without evidence of intracranial hemorrhage, peri-ventricular leukomalacia or ventriculomegaly? Y

   If Yes, Go to Question D5

   b. Date of sonogram for most severe findings:
   Month Day Year

   c. Blood/echodensity in germinal matrix/subependymal area?

	(1) RIGHT	(2) LEFT
d. Blood/echodensity in the ventricle?		
e. Ventricular size enlarged with concurrent or prior blood in the ventricles?		
f. Ventricular size enlarged without concurrent or prior blood in the ventricles?		
g. Blood/echo-density in the parenchyma?		

4. Cystic area(s) in the parenchyma within 28 days?

   If YES,

	(1) RIGHT	(2) LEFT
a. Cystic periventricular leukomalacia within 28 days?		
b. Porencephalic cyst within 28 days?		

5. Were any cranial imaging studies done after 28 days of birth? Y

   If NO, Go to Section E.

6. Cranial sonogram closest to 36 weeks postmenstrual age and after 28 days of birth:

   a. Type of imaging (1=MRI, 2=Sonogram, 3=CT scan) 2

   b. Date of image: (b) (6)
   Month Day Year

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

c. Normal study? Y

If NO,

	(1) RIGHT	(2) LEFT
d. Ventricular size enlarged?		
e. Cystic periventricular leukomalacia?		
f. Porencephalic cyst?		

E. INFECTIO

1. Early onset septicemia/bacteremia at (<= 72 hours)? N
   If YES, organism code(s): a. b.
2. Did the infant receive antibiotics for >= 5 days, starting within the first 72 hours? Y
3. Number of episodes of late onset blood culture negative clinical infection (>=72 hours to status) treated with antibiotics for >= 5 days: 06
4. Late onset culture positive septicemia/bacteremia (>= 72 hours)? Y
   If YES,
   a. Number of episodes between day 3 and status that were treated with antibiotics for >= 5 days: 00
   b. Organism code(s) and date of first positive culture for each of episodes for which the infant was treated with antibiotics for >= 5 days:

a)Episode#	(b) Date	(1) Organism	(2) Organism	(3) Organism
1				
2				
3				
4				
5				
6				

5. Meningitis? N
   a. If YES,

a)Episode#	(b) Date	(1) Organism	(2) Organism	(3) Organism
1				
2				

F. GASTROINTESTINAL

1. Did weight ever fall below the birth weight during the first 10 days? Y
   If YES,
   a. Lowest weight in the first 10 days? 0651
   b. Date of lowest weight in the first 10 days: (b) (6)
   c. Was birth weight regained? Y
   If YES
   d. Date birth weight first regained: (b) (6)

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

2. Did the baby receive patenteral alimentation? **Y**

   If YES,

   a. Date of first patenteral alimentation **(b) (6)**

   b. Total number of days: **031**

3. Did the baby receive enteral feeds? **Y**

   If YES,

   a. Date of first enteral feed: **(b) (6)**

   b. Did enteral feeds reach 120 ml/kg/day? **Y**

      1) If YES, date first achieved: **(b) (6)**

   c. Did the baby receive breast milk in the first 28 days? **Y**

      1) If YES, number of days baby received any breast milk in first 28 days: **02**

4. Proven NEC: **0**

   0 = Absent/Suspect 2 = Proved, no surgery 3 = Proved, surgery

   a. If proven NEC, Date of first episode?

   Month Day Year

5 Spontaneous gastrointestinal perforation without proven NEC? **N**

   a. If YES, date of the first spontaneous gastrointestinal perforation:

   Month Day Year

6. Did the infant have GI surgery that resulted in short gut? **N**

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

CENTER: 19 NETWORK: (b) (6) SITENM: (b) (6) Mother's Initials: , Birth No: 1

G. HEARING

1. Was a Hearing screen performed? **Y**

   a. If YES, hearing screen protocol used: **3**

   1 = OAE 2 = AABR 3 = ABR 4 = OAE + AABR 5 = Other

   b. Final screen results before discharge

      i) Right ear: **1**

      ii) Left ear: **1**

   Results: 1. Pass 2. Fail 3. Incomplete

   c. If a failed screen in either ear, was a diagnostic ABR done prior to status?

      1) If YES, answer the following:

         i) Right ear:

         ii) Left ear:

   Results: 1. Pass 2. Fail 3. Incomplete

H. OPHTHALMOLOGY

1. Was an exam performed for ROP? **Y**

   If Yes,

   a. Was ROP diagnosed in either eye? **Y**

      If Yes,

      1) Did it reach stage 3 or worse in either eye? **Y**

      2) Did plus disease develop in either eye? **Y**

      3) Other therapies **N**

         (if yes, specify):

   b. Intervention Therapies:

      1. Was retinal ablation performed in either eye (laser and/or cryotherapy)? **Y**

      2. Was any scleral buckle or vitrectomy performed in either eye? **N**

2. At the time of reaching status, indicate the most appropriate: **1**

   1 = Determined, favorable in both eyes

   2 = Determined, severe ROP in either eye

   3 = Undetermined ROP status in either eye (and neither had "severe ROP")

1. Determined Favorable:
   - Vessels mature (fully vascularized)
   - Vessels in zone III for two consecutive exams
   - ROP of stage 1 or 2 in zone III for two consecutive exams
   - ROP in zone II or zone III but determined to be clearly regressing

2. Determined-Severe:
   - ROP surgery
   - Retinal detachment
   - Avastin injection

3. Undetermined:
   - Immature Vessels in zone I and II
   - Immature Vessels reaching zone III for only 1 exam
   - Stage 1 or 2 ROP in zone III for only 1 exam
   - Stage 3 ROP in zone III
   - ROP in zone I or zone II
   - Plus disease

   4) = | 5) =

   b) If a syndrome is coded "699", specify:

J. MAJOR SURGERY

1. Other major surgery not covered in previous sections? N

   a. If YES, code:

   1) = | 2) = | 3) =
   4) = | 5) =

   i) If a major surgery is coded 999, specify:

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

K. 36 WEEK INFORMATION

1. Status at 36 weeks: 2

1 = Discharged 2 = In hospital 3 = Transferred 5 = Death

If "2", (In Hospital):

a. Date of 36 weeks measurement: (b) (6)
Month Day Year

b. Weight (g) 0885

c. Length (cm): **.*

d. Head circumference (cm) **.*

L. FEEDING STATUS:

1. Type of nutrition at discharge to home. Code all that apply

(Do not complete for transfer patients):

1 = Breastmilk 2 = Formula 3 = TPN

2. If enteral, Mode:

1 = Breast 2 = Bottle 3 = NG/NJ tube 4 = Gastrostomy tube 9 = Unknown

M. TRANSFER

Complete this section if status (AI) of infant at time of completion of this form is "3" or "4".

1. Date of transfer:
Month Day Year

2. Final outcome:

1 = Died in Hospital 2 = Discharged to Home 6 = Remains in hospital at one year

a. If discharged to home, final weight at discharge (grams):

N. DISCHARGE ALIVE

Complete this section if status (Q. A1 above) of infant at time of completion of this form is "1" or if the final outcome for a transferred infant is 'Discharged to home.'

1. Date of discharge to home:
Month Day Year

2. Discharged home on continuous oxygen?

3. Discharged home on any of the following medications?

If YES,

a. Diuretics?

b. Bronchodilators?

c. Anticonvulsants?

d. Antireflux medications?

O. DEATH

1. Date of Death:
Month Day Year

a. Time of Death
Hours Minutes

2. Autopsy performed?

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

3. Contributory Cause of death

```
Malformation                                    NEC
10 = Congenital malformation                      40 = NEC
Pulmonary                                         41 = NEC with sepsis
20 = RDS                                        CNS Insult
21 = RDS with severe intracranial hemorrhage      50 = Severe intracranial
hemorrhage                                      Other
22 = RDS with infection                           60 = Immaturity
25 = BPD                                          90 = Other
26 = BPD with infection                           99 = Unknown
27 = BPD with severe CNS insult
Infection
30 = Suspect sepsis/infection
31 = Proven sepsis/infection
```

4. If contributory cause of death is code "10" (Congenital malformation), or code "90" (other), specify:

5. Was respiratory support withheld or withdrawn at any time prior to death?

2. At the time of reaching status, indicate the most appropriate: **3**

   1 = Determined, favorable in both eyes

   2 = Determined, severe ROP in either eye

   3 = Undetermined ROP status in either eye (and neither had "severe ROP")

```
1. Determined Favorable:
   -    Vessels mature (fully vascularized)
   -    Vessels in zone III for two consecutive exams
   -    ROP of stage 1 or 2 in zone III for two consecutive exams
   -    ROP in zone II or zone III but determined to be clearly regressing
```

```
2.  Determined-Severe:
    -    ROP surgery
    -    Retinal detachment
    -    Avastin injection
```

```
3.  Undetermined:
    -    Immature Vessels in zone I and II
    -    Immature Vessels reaching zone III for only 1 exam
    -    Stage 1 or 2 ROP in zone III for only 1 exam
    -    Stage 3 ROP in zone III
    -    ROP in zone I or zone II
    -    Plus disease
```

Maybe we should go ahead with identification of the group of experts to adjudicate the ROP outcomes as the data will be limited in a substantial proportion of babies.

Subject: SUPPORT missing data updates

Attached are is the list of SUPPORT infants who are currently missing outcome data. A few things to note:

1) Our N is now 1317 instead of 1316 because Duke just entered forms for an infant whose parent had consented for SUPPORT but who did not consent to GDB until the 18 month FU visit.
2) A few new BPD missing data reminders have been generated for Duke based on recent edits to their data. Kris also has a list of those cases so that they can be addressed at the site visit on Tuesday.
3) We are missing ROP outcomes on 112 infants. Three of those were withdrawn from the study so we probably have all the data we can get on them. There are 2 cases where the infants had vessels in zone 1 at the last exam, 55 cases with vessels in zone 2 at the last exam, and 52 cases where there were vessels in zone 3 at the last exam but not at two consecutive exams (see attached report for details).

My next steps will be to check on the resolution of the BPD and other cross-form queries. Have a good weekend.

Hi Rose
Mostly we are using survival without NDI and survival without BPD rates for infants of 23 to 28 weeks. I would assume that we would have used that last complete years for NDI. As for the years I think that Kris can tell you that- probably 2006-8.
We are using US rates and have cross referenced with VON. For the death etc and BPD they are close.
Thanks
Neil

Hi Rose
We have used the GDB information via RTI to calculate some sample sizes for our proposed PRESOX Study.
I am not sure whether we would be considered as having permission to use this data for this purpose.
We have acknowledged the source of the data as being from the NRN GDB. I would like to ask whether we need permission and if so, whether you would be so good as to ask the Steering Committee for this.
We are not using any forms from the Network or SUPPORT for this proposed trial
Many thanks for considering this request.
Be well
Neil

Subject SUPPORT!!!!

Hi,
We are missing a few SUPPORT Primary outcomes. Please get these entered ASAP as we want to lock the database.

Thanks for all the effort!!
Rose

Subject: SUPPORT missing data updates

Attached are is the list of SUPPORT infants who are currently missing outcome data. A few things to note:

1) Our N is now 1317 instead of 1316 because Duke just entered forms for an infant whose parent had consented for SUPPORT but who did not consent to GDB until the 18 month FU visit.
2) A few new BPD missing data reminders have been generated for Duke based on recent edits to their data. Kris also has a list of those cases so that they can be addressed at the site visit on Tuesday.
3) We are missing ROP outcomes on 112 infants. Three of those were withdrawn from the study so we probably have all the data we can get on them. There are 2 cases where the infants had vessels in zone 1 at the last exam, 55 cases with vessels in zone 2 at the last exam, and 52 cases where there were vessels in zone 3 at the last exam but not at two consecutive exams (see attached report for details).

My next steps will be to check on the resolution of the BPD and other cross-form queries. Have a good weekend.

Thanks,
Marie

Subject: RE: Support IDs

Hi – see if the attached document is OK. I have BPD and ROP data on separate pages – if that's a problem I'll try to figure out some other format. I've included a note after the BPD data to point out cases that used to have the NG07 snapshot data but now do not. Also, there is a note for the infant who used to have an NG03 but now does not. Let me know if you need anything else!

Thanks,
Marie

Hi all,

Thanks for your patience while I was away. I have made few edits and comments to the latest version of Wally's paper. Wally, you had mentioned that you were missing some outcomes (like IVH/death) and I believe those were included in tables I sent on Sept. 3 (T2S Major Outcomes - PRELIMINARY 03SEP09.doc) – let me know if you need me to resend them.

Regarding the earlier question about the numbers in figure 1 differing from the monthly report, in the monthly report "*Eligible GDB patients are those keyed in the NG02 (inborn and GA*

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

of 24 0/6 & 27 6/7) with a birth date after the first Support patient keyed for sites at each Center and not born on or between dates of Support study suspension 11/23/2005 and 2/5/2006" while the 3546 in figure 1 are those infants who were entered on the SUPP01 screening log. I'm not sure what to do about the difference unless we add them to the number who were "eligible but consent not sought." We should also be clear in figure 1 that many more moms were screened than are reflected on the SUPP01, because only those infants who were eventually assigned a GDB number (or who were enrolled in SUPPORT) were entered into the DMS. We could reference Wade's antenatal consent paper for a more accurate estimate of how many moms were screened.

FYI, while I was gone, queries went out to the centers regarding data that differed across GDB and SUPPORT forms and that will impact the secondary outcomes (including things like IVH) to some (hopefully small) degree. We have heard back from 10 centers so far, and I will review the results of the queries as we get responses to make sure all the necessary data are cleaned. I will also re-review the BPD outcome data to see if those queries have been completely cleared up yet and I will remind centers of any outstanding queries.

Thanks,
Marie

ABSTRACT

Background

Non randomized studies suggest that the incidence of retinopathy decreases in premature infants with exposure oxygenation levels lower than previously maintained. However, the range of oxygen saturations that reduces retinopathy without increasing adverse outcomes is not known.

Methods

1316 infants of 24 to 27 weeks gestation born at 20 centers of the Neonatal Research Network were randomly assigned at birth to oxygen saturation targets of 85 to 89% or 91 to 95%. The primary outcome was a composite of threshold retinopathy of prematurity, eye surgery for retinopathy, and/or death.

Results

Conclusions

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

INTRODUCTION

Retinopathy of prematurity remains an important cause of blindness and other visual disabilities in prematurely born infants. The incidence of retinopathy of prematurity increased with exposure to unrestricted oxygen in premature infants in randomized controlled trials performed in the 1950s.[1] However, in subsequent years, the practice of restricting oxygen supplementation was estimated to result in an excess of 16 deaths per case of blindness prevented.[2] More recent data suggest that oxygen saturation levels previously thought to be in the upper limits of normal appear to also increase the risk of retinopathy of prematurity.[3-5] Oxygen toxicity may also increase the risk of mortality[6, 7], bronchopulmonary dysplasia[8-10], periventricular leukomalacia[11], cerebral palsy[12], and other morbidities. Although a multicenter study [13] could not determine an association between oxygen levels and retinopathy, a single center cohort study using transcutaneous oxygen monitoring supported the association of retinopathy with exposure to arterial oxygen levels $\geq$ 80mmHg.[14]

The recent introduction of pulse oximeters into the neonatal intensive care units, have allowed clinicians to utilize oxygen saturations to target oxygenation in premature infants. A survey study of 144 neonatal intensive care units conducted in 2001, revealed that the average lower limit of target oxygen saturations was 90% and the upper limit was 96%.[5] In recent years, the use of high saturation targets has been associated with the increased risk for retinopathy. The rate of retinal ablation surgery was higher at neonatal intensive care units with maximal target oxygen saturation $\geq$ 98% (5.6 $\pm$ 1.1 versus 3.1 $\pm$ 0.3%) or $\geq$ 92% (3.3 $\pm$ 0.3 versus 1.4 $\pm$ 0.2%).[5] Recent studies suggest that oxygen saturation targeting from the first day after birth at levels lower than previously used may reduce the incidence of retinopathy. In a retrospective study comparing outcomes at five neonatal intensive care units, the incidence of severe

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

retinopathy requiring ablation therapy was 27% in units where target saturations were 88 to 98% and only 6% in units where the target was 70 to 90%.[3] Rates of mortality and cerebral palsy did not differ in these units. In three other studies, a policy of oxygen saturation targeting of approximately 83 to 95% resulted in a substantial reduction in retinopathy.[4, 15, 16] However, in these studies, actual oxygen saturations achieved were not reported. Pulse oximetry has become the standard technique for continuous monitoring of oxygenation. While data from recent prospective observational and retrospective studies[3, 4, 15-19] suggest that maintenance of oxygenation at ranges lower than previously used may decrease the incidence of retinopathy of prematurity, there is no conclusive evidence that these oxygenation levels do so without an increase in serious adverse effects.

We conducted a 2 x 2 factorial-design multicenter randomized trial of oxygen saturation targeting and ventilation strategy. ~~. testing~~ The oxygen saturation arm tested the effect of a lower oxygen saturation target range (85-89%) ~~as~~ compared to a higher oxygen saturation target range (91-95%) on the incidence of threshold retinopathy of prematurity, eye surgery for retinopathy, and/or death among infants of 24 to 27 weeks gestational age at birth. ~~The factorial design allowed comparison~~ The ventilation arm tested the effect of ~~of~~ prophylactic/early surfactant versus continuous positive airway pressure~~; thus, controlling for the approach to ventilatory support~~ on bronchopulmonary dysplasia or death at 36 weeks postmenstrual age.

METHODS

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

The institutional review boards at all Neonatal Research Network clinical centers and at Research Triangle International (data center) approved the trial. Written informed consent was obtained from the parent or guardian of each participant before delivery.

Patients

Infants of $24^{0/7}$ to $27^{6/7}$ weeks gestational age, without a decision to forgo support were eligible for enrollment at birth. Exclusion criteria were outborn infants and major congenital anomalies. Multiple births were randomized to the same arm of the trial.

Enrollment and treatment

Infants were stratified by center and by gestational age ($24^{0/7}$ to $25^{6/7}$ weeks or $26^{0/7}$ to $27^{6/7}$ weeks). Infants were randomly assigned by means of double-sealed envelopes to oxygen saturation targeting of 85 to 89% or 91 to 95%. Masking was maintained using electronically-altered pulse oximeters with output display of 88 to 92% for these oxygen ranges, an offset of 3% as previously used to separate oxygen saturations in premature infants.[20] Participants were also randomly assigned to respiratory support using either prophylactic/early surfactant with conventional ventilation management or to continuous positive airway pressure with a permissive ventilatory strategy. The oxygen saturation values displayed reverted to actual values when less than 845% or greater than 965%. Oxygen saturation targeting with the altered pulse oximetry was initiated within the first two hours after birth and was continued until 36 weeks post-menstrual age or until the infant remained on room air and off the ventilator/continuous positive airway pressure for more than 72 hours. Infants weaned to room air but who subsequently received oxygen supplementation before 36 weeks post-menstrual age were

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

placed back on the assigned study pulse oximetry. Adjustments in supplemental oxygen to target oxygen saturations were performed by the clinicians, not by the research staff.

Assessments

Research nurses recorded all data using standardized definitions. Data were collected until discharge or 120 days postnatal age whichever occurred first. Threshold retinopathy of prematurity (New Type 1 threshold per Early Treatment of Retinopathy [ETROP] Cooperative Group[21]) was coded if any of the following four findings were present up to 55 weeks post-menstrual age:

If in zone 1: Stage 3 retinopathy of prematurity, even without plus disease

Plus disease with any stage retinopathy of prematurity

If in zone II: Plus disease with stage 2 retinopathy of prematurity

Plus disease with stage 3 retinopathy of prematurity

Surgical intervention included laser therapy, cryotherapy, laser/cryotherapy, scleral buckle, and vitrectomy. Outcomes included predefined clinical diagnoses and potential adverse events.

Comment [MG1]: We are also including treatment with Avastin, correct?

Statistical analysis

The primary analysis for the oxygen saturation arm of this factorial trial was a ~~logistic regression~~ generalized estimating equation (GEE) model that used robust Poisson regression to produce adjusted relative risks comparing ~~analysis of~~ the percentages of infants in each group (lower versus higher oxygen saturations) who developed the primary outcome. The model adjusted for stratification by center and gestational age and for the randomization of multiple births to the same treatment. An absolute difference of 10% between the two treatment groups was considered clinically important. To detect this difference, we planned to enroll ~~1312~~ 1310 infants for 80% power to detect a 10% difference in outcome

Comment [MG2]: This is what is listed on clinicaltrials.gov

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

assuming ~~and~~ a baseline estimated rate of ~~45~~50% of death/threshold retinopathy/surgery. This sample size estimate included ~~. based on~~ an increase by a factor of 1.12 to account for randomizing multiples to the same treatment group and on an increase by a factor of 1.17 to account for the expected attrition after discharge and before follow up. The trial was not powered to determine an interaction between the two interventions. Intention-to-treat analyses were performed. The denominator used to calculate the rate of each outcome was the number of infants for whom that outcome was known. Analyses were conducted by the data center. A two-sided P value of less than 0.05 was considered to be statistically significant. Analyses did not include adjustment for multiple comparisons. An independent data safety and monitoring committee reviewed the primary outcomes, adverse events, and other interim results at ~25%, 50%, and 75% of planned enrollment. Lan-DeMets spending functions with Pocock boundaries were used to develop stopping rules for interim safety monitoring.

Comment [MG3]: The final DSMC review will take place on November 4 to review 100% of the BPD/death data and as much of the ROP data as we have at that time.

RESULTS

1316 infants were enrolled between January 2004 and March 2009 (Figure 1). Enrollment was temporarily stopped by the Data Safety and Monitoring Committee because of concerns regarding compliance with oxygen saturation targets. Separate of analysis of the oximetry data while on room air versus while on oxygen supplementation resolved the concerns. The baseline characteristics of the lower saturation group and the higher saturation group were similar (Table 1).

Major outcomes

The Data Safety and Monitoring Committee masked interim analyses were made available to the investigators after enrollment was completed. There had been a trend for increased mortality in one of the treatment groups that had not reached the stopping boundary. The principal investigator and data

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

center staff undertook a safety analysis to evaluate potential adverse outcomes without unblinding the retinopathy outcome data. This manuscript reports the hospital outcomes. Retinopathy and 18-22 month follow up outcomes will be reported later.

Mortality at any time during hospitalization occurred in 130 of the 655 (20%) of the infants in the lower oxygen saturation group versus in 106 of the 661 (16%) of the infants in the higher oxygen saturation group (RR 0.78, CI 0.62, 0.99, P=0.04). Comparable results were observed in both gestational age groups used for stratification. Mortality in the first and second weeks after birth was comparable in the two groups (Table 2). Other prespecified major outcomes were comparable between the two treatment groups (Table 2).

The median oxygen saturation of both groups differed substantially but, as expected, there was some overlap (Figure 2). These data indicate that actual oxygen saturation levels are slightly higher than targets in both treatment groups. The duration of oxygen supplementation was shorter in the lower oxygen saturation group but the duration of mechanical ventilation, continuous positive airway pressure, and nasal synchronized intermittent mandatory ventilation did not differ (Table 3). Other measures of resource utilization did not differ.

DISCUSSION

The recommended ranges of oxygen saturation targeting for very preterm infants have been determined from nonrandomized studies and restriction of oxygen supplementation is becoming the standard practice.[3, 22] However, there was an increase in mortality when a restrictive oxygen supplementation

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

was practiced in the 1950s and 1960s. Despite not~~w~~ being based on randomized controlled trials and limited evidence of safety, lower oxygen saturation targeting has become ~~the recommended~~increasingly adopted by units and physicians who are desirous of decreasing significant retinopathy of prematurity. In the current trial, lower oxygen saturation targeting (85-89%) resulted in an increased risk of mortality.

This trial was not prospectively powered for a difference in mortality only between the two oxygen saturation groups and, thus, the results should be viewed with caution. However, this is the largest completed prospective randomized trial to test the effect of lower versus higher oxygen saturation targeting and the results add to previous data raising the concern that oxygen restriction may increase mortality in very preterm infants. The infants in this trial were more immature than those of any previous trails of oxygen restriction and, thus, may have had a higher susceptibility to the effects of lower oxygen saturation targeting. In addition, aside from the decreased use of oxygen supplementation at 36 weeks, there were no other benefits from oxygen restriction. The previous data on the increased mortality from oxygen restriction were from studies with lower levels of evidence ~~rather than~~compared to randomized controlled trials. It is interesting and worrisome that the ~~,~~combined risk difference observed in the 1950s ~~except for the trends in the 1950s which had a combined risk difference of~~~~was a~~ was a 4.9% increase in mortality in the oxygen restricted group very similar to our 4% mortality increase in the lower targeted SpO2 group. (Ref 1).

Comment [MG4]: Although death was not the pre-specified primary outcome, the fact that the study was not specifically powered to detect a difference in death rate should not in itself lead us to be cautious about the findings. Recall that the study was powered conservatively for an outcome rate of 50% . It turned out that we also had the power to detect a difference in death rates of 16% vs. 20%.

Restriction of oxygenation in the randomized controlled trials in preterm infants beyond the first weeks of life did not show trends for increased mortality in the lower saturation target groups.[17, 18] However, these trials aimed for saturations of 91 to 94% and 89 to 94% in the lower oxygen saturation group.

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

Mortality in the current trial did not differ by 7 or 14 days. Therefore, the lower target of oxygen saturations rather than the postnatal age of the intervention may be related to the adverse outcome.

There are several ongoing trials that address the same intervention tested in the current trial as well as a planned prospective meta-analysis.[1] At the present time, it is important that these trials continue.~~. It is also~~and it will be important that the investigators and the data safety and monitoring committees of these trials are aware of the results of the current trial so appropriate decisions can be made regarding their interim analyses, completion of the trials, and dissemination of the data. The current trial raises the concern of adverse hospital outcomes due to oxygen saturation targeting in the 85 to 89% range. Further information from the ongoing randomized controlled trials that evaluate lower versus higher oxygen saturation targeting will become available in the next years but at the present time, caution should be exercised regarding oxygen targeting in the low range tested in the current trial.

Hi Wally
I have made a few changes
Be well
Neil

From: Wally Carlo, M.D. [mailto:WCarlo@peds.uab.edu]
Sent: Friday, September 18, 2009 1:29 PM
To: Finer, Neil; Higgins, Rosemary (NIH/NICHD) [E]; Das, Abhik; Gantz, Marie
Cc: Wally Carlo, M.D.
Subject: Oxygen saturation targeting paper

Dear Neil, Rose, Abhik, and Marie:

I have made several changes including:
1. Making Neil's suggestions
2. Improved Figure 2
3. Included Figure 1
4. Multiple minor changes.

I have made changes in all the numbers of the results as Abhik said they are still not final.

Enclosed is a clean draft so you can see my comments. I think we need to consider adding the ROP data if it is final before the paper is ready for submission.

I would appreciate any comments.

Thanks
Wally

ABSTRACT

Background

Non randomized studies suggest that the incidence of retinopathy decreases in premature infants with exposure oxygenation levels lower than previously maintained. However, the range of oxygen saturations that reduces retinopathy without increasing adverse outcomes is not known.

Methods

1316 infants of 24 to 27 weeks gestation born at 20 centers of the Neonatal Research Network were randomly assigned at birth to oxygen saturation targets of 85 to 89% or 91 to 95%. The primary outcome was a composite of threshold retinopathy of prematurity, eye surgery for retinopathy, and/or death.

Results

Conclusions

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

INTRODUCTION

Retinopathy of prematurity remains an important cause of blindness and other visual disabilities in prematurely born infants. The incidence of retinopathy of prematurity increased with exposure to unrestricted oxygen in premature infants in randomized controlled trials performed in the 1950s.[1] However, in subsequent years, the practice of restricting oxygen supplementation was estimated to result in an excess of 16 deaths per case of blindness prevented.[2] More recent data suggest that oxygen saturation levels previously thought to be in the upper limits of normal appear to also increase the risk of retinopathy of prematurity.[3-5] Oxygen toxicity may also increase the risk of mortality[6, 7], bronchopulmonary dysplasia[8-10], periventricular leukomalacia[11], cerebral palsy[12], and other morbidities. Although a multicenter study [13] could not determine an association between oxygen levels and retinopathy, a single center cohort study using transcutaneous oxygen monitoring supported the association of retinopathy with exposure to arterial oxygen levels $\geq$ 80mmHg.[14]

The recent introduction of pulse oximeters into the neonatal intensive care units, have allowed clinicians to utilize oxygen saturations to target oxygenation in premature infants. A survey study of 144 neonatal intensive care units conducted in 2001, revealed that the average lower limit of target oxygen saturations was 90% and the upper limit was 96%.[5] In recent years, the use of high saturation targets has been associated with the increased risk for retinopathy. The rate of retinal ablation surgery was higher at neonatal intensive care units with maximal target oxygen saturation $\geq$ 98% (5.6 $\pm$ 1.1 versus 3.1 $\pm$ 0.3%) or $\geq$ 92% (3.3 $\pm$ 0.3 versus 1.4 $\pm$ 0.2%).[5] Recent studies suggest that oxygen saturation targeting from the first day after birth at levels lower than previously used may reduce the incidence of retinopathy. In a retrospective study comparing outcomes at five neonatal intensive care units, the incidence of severe

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

retinopathy requiring ablation therapy was 27% in units where target saturations were 88 to 98% and only 6% in units where the target was 70 to 90%.[3] Rates of mortality and cerebral palsy did not differ in these units. In three other studies, a policy of oxygen saturation targeting of approximately 83 to 95% resulted in a substantial reduction in retinopathy.[4, 15, 16] However, in these studies, actual oxygen saturations achieved were not reported. Pulse oximetry has become the standard technique for continuous monitoring of oxygenation. While data from recent prospective observational and retrospective studies[3, 4, 15-19] suggest that maintenance of oxygenation at ranges lower than previously used may decrease the incidence of retinopathy of prematurity, there is no conclusive evidence that these oxygenation levels do so without an increase in serious adverse effects.

We conducted a 2 x 2 factorial-design multicenter randomized trial of oxygen saturation targeting, testing the effect of a lower oxygen saturation range (85-89%) as compared to a higher oxygen saturation range (91-95%) on the incidence of threshold retinopathy of prematurity, eye surgery for retinopathy, and/or death among infants of 24 to 27 weeks gestational age at birth. The factorial design allowed comparison of prophylactic/early surfactant versus continuous positive airway pressure; thus, controlling for the approach to ventilatory support.

METHODS

The institutional review boards at all Neonatal Research Network clinical centers and at Research Triangle International (data center) approved the trial. Written informed consent was obtained from the parent or guardian of each participant before delivery.

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

Patients

Infants of $24^{0/7}$ to $27^{6/7}$ weeks gestational age, without a decision to forgo support were eligible for enrollment at birth. Exclusion criteria were outborn infants and major congenital anomalies. Multiple births were randomized to the same arm of the trial.

Enrollment and treatment

Infants were stratified by center and by gestational age ($24^{0/7}$ to $25^{6/7}$ weeks or $26^{0/7}$ to $27^{6/7}$ weeks). Infants were randomly assigned by means of double-sealed envelopes to oxygen saturation targeting of 85 to 89% or 91 to 95%. Masking was maintained using electronically-altered pulse oximeters with output display of 88 to 92% for these oxygen ranges, an offset of 3% as previously used to separate oxygen saturations in premature infants.[20] Participants were also randomly assigned to respiratory support using either prophylactic/early surfactant with conventional ventilation management or to continuous positive airway pressure with a permissive ventilatory strategy. The oxygen saturation values displayed reverted to actual values when less than 85% or greater than 95%. Oxygen saturation targeting with the altered pulse oximetry was initiated within the first two hours after birth and was continued until 36 weeks post-menstrual age or until the infant remained on room air and off the ventilator/continuous positive airway pressure for more than 72 hours. Infants weaned to room air but who subsequently received oxygen supplementation before 36 weeks post-menstrual age were placed back on the assigned study pulse oximetry. Adjustments in supplemental oxygen to target oxygen saturations were performed by the clinicians, not by the research staff.

Assessments

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

Research nurses recorded all data using standardized definitions. Data were collected until discharge or 120 days postnatal age whichever occurred first. Threshold retinopathy of prematurity (New Type 1 threshold per Early Treatment of Retinopathy [ETROP] Cooperative Group[21]) was coded if any of the following four findings were present up to 55 weeks post-menstrual age:

If in zone 1: Stage 3 retinopathy of prematurity, even without plus disease

Plus disease with any stage retinopathy of prematurity

If in zone II: Plus disease with stage 2 retinopathy of prematurity

Plus disease with stage 3 retinopathy of prematurity

Surgical intervention included laser therapy, cryotherapy, laser/cryotherapy, scleral buckle, and vitrectomy. Outcomes included predefined clinical diagnoses and potential adverse events.

Statistical analysis

The primary analysis of this factorial trial was a logistic regression analysis of the percentages of infants in each group (lower versus higher oxygen saturations) who developed the primary outcome. An absolute difference of 10% between the two treatment groups was considered clinically important. To detect this difference, we planned to enroll 1312 infants for 80% power and a baseline estimated rate of 45% of death/threshold retinopathy/surgery, based on an increase by a factor of 1.12 to account for randomizing multiples to the same treatment group and on an increase by a factor of 1.17 to account for the expected attrition after discharge and before follow up. The trial was not powered to determine an interaction between the two interventions. Intention-to-treat analyses were performed. The denominator used to calculate the rate of each outcome was the number of infants for whom that outcome was known. Analyses were conducted by the data center. A two-sided P value of less than 0.05 was considered to be statistically significant. Analyses did not include adjustment for multiple comparisons.

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

An independent data safety and monitoring committee reviewed the primary outcomes, adverse events, and other interim results at ~25%, 50%, and 75% of planned enrollment. Pocock boundaries were used to develop stopping rules for interim safety monitoring.

RESULTS

1316 infants were enrolled between January 2004 and March 2009 (Figure 1). Enrollment was temporarily stopped by the Data Safety and Monitoring Committee because of concerns regarding compliance with oxygen saturation targets. Separate of analysis of the oximetry data while on room air versus while on oxygen supplementation resolved the concerns. The baseline characteristics of the lower saturation group and the higher saturation group were similar (Table 1).

Major outcomes

The Data Safety and Monitoring Committee masked interim analyses were made available to the investigators after enrollment was completed. There had been a trend for increased mortality in one of the treatment groups that had not reached the stopping boundary. The principal investigator and data center staff undertook a safety analysis to evaluate potential adverse outcomes without unblinding the retinopathy outcome data. This manuscript reports the hospital outcomes. Retinopathy and 18-22 month follow up outcomes will be reported later.

Mortality at any time during hospitalization occurred in 130 of the 655 (20%) of the infants in the lower oxygen saturation group versus in 106 of the 661 (16%) of the infants in the higher oxygen saturation group (RR 0.78, CI 0.62, 0.99, P=0.04). Comparable results were observed in both gestational age groups used for stratification. Mortality in the first and second weeks after birth was comparable in the

two groups (Table 2). Other prespecified major outcomes were comparable between the two treatment groups (Table 2).

The median oxygen saturation of both groups differed substantially but, as expected, there was some overlap (Figure 2). These data indicate that actual oxygen saturation levels are slightly higher than targets in both treatment groups. The duration of oxygen supplementation was shorter in the lower oxygen saturation group but the duration of mechanical ventilation, continuous positive airway pressure, and nasal synchronized intermittent mandatory ventilation did not differ (Table 3). Other measures of resource utilization did not differ.

DISCUSSION

The recommended ranges of oxygen saturation targeting for very preterm infants have been determined from nonrandomized studies and restriction of oxygen supplementation is becoming the standard practice.[3, 22] However, there was an increase in mortality when a restrictive oxygen supplementation was practiced in the 1950s and 1960s. Despite not~~w~~ being based on randomized controlled trials and limited evidence of safety, lower oxygen saturation targeting has become ~~the recommended~~increasingly adopted by units and physicians who are desirous of decreasing significant retinopathy of prematurity. In the current trial, lower oxygen saturation targeting (85-89%) resulted in an increased risk of mortality.

This trial was not prospectively powered for a difference in mortality only between the two oxygen saturation groups and, thus, the results should be viewed with caution. However, this is the largest completed prospective randomized trial to test the effect of lower versus higher oxygen saturation

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

targeting and the results add to previous data raising the concern that oxygen restriction may increase mortality in very preterm infants. The infants in this trial were more immature than those of any previous trails of oxygen restriction and, thus, may have had a higher susceptibility to the effects of lower oxygen saturation targeting. In addition, aside from the decreased use of oxygen supplementation at 36 weeks, there were no other benefits from oxygen restriction. The previous data on the increased mortality from oxygen restriction were from studies with lower levels of evidence ~~rather than~~compared to randomized controlled trials. It is interesting and worrisome that the ~~,~~combined risk difference observed in the 1950s ~~except for the trends in the~~ 1950s ~~which had a combined risk difference of~~was a was a 4.9% increase in mortality in the oxygen restricted group very similar to our 4% mortality increase in the lower targeted SpO2 group. (Ref 1).

Restriction of oxygenation in the randomized controlled trials in preterm infants beyond the first weeks of life did not show trends for increased mortality in the lower saturation target groups.[17, 18] However, these trials aimed for saturations of 91 to 94% and 89 to 94% in the lower oxygen saturation group. Mortality in the current trial did not differ by 7 or 14 days. Therefore, the lower target of oxygen saturations rather than the postnatal age of the intervention may be related to the adverse outcome.

There are several ongoing trials that address the same intervention tested in the current trial as well as a planned prospective meta-analysis.[1] At the present time, it is important that these trials continue.~~,~~ ~~It is also~~and it will be important that the investigators and the data safety and monitoring committees of these trials are aware of the results of the current trial so appropriate decisions can be made regarding their interim analyses, completion of the trials, and dissemination of the data. The current trial raises the concern of adverse hospital outcomes due to oxygen saturation targeting in the 85 to 89% range. Further

information from the ongoing randomized controlled trials that evaluate lower versus higher oxygen saturation targeting will become available in the next years but at the present time, caution should be exercised regarding oxygen targeting in the low range tested in the current trial.

Subject: Oxygen saturation targeting paper
Date: Friday, September 18, 2009 4:28:52 PM
Attachments: Oxygen Saturation Targeting.9.18.09.doc

Dear Neil, Rose, Abhik, and Marie:

I have made several changes including:
1. Making Neil's suggestions
2. Improved Figure 2
3. Included Figure 1
4. Multiple minor changes.

I have made changes in all the numbers of the results as Abhik said they are still not final.

Enclosed is a clean draft so you can see my comments. I think we need to consider adding the ROP data if it is final before the paper is ready for submission.

I would appreciate any comments.

Thanks
Wally

ABSTRACT

Background

Non randomized studies suggest that the incidence of retinopathy decreases in premature infants with exposure oxygenation levels lower than previously maintained. However, the range of oxygen saturations that reduces retinopathy without increasing adverse outcomes is not known.

Methods

1316 infants of 24 to 27 weeks gestation born at 20 centers of the Neonatal Research Network were randomly assigned at birth to oxygen saturation targets of 85 to 89% or 91 to 95%. The primary outcome was a composite of threshold retinopathy of prematurity, eye surgery for retinopathy, and/or death.

Results

Conclusions

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

INTRODUCTION

Retinopathy of prematurity remains an important cause of blindness and other visual disabilities in prematurely born infants. The incidence of retinopathy of prematurity increased with exposure to unrestricted oxygen in premature infants in randomized controlled trials performed in the 1950s.[1] However, in subsequent years, the practice of restricting oxygen supplementation was estimated to result in an excess of 16 deaths per case of blindness prevented.[2] More recent data suggest that oxygen saturation levels previously thought to be in the upper limits of normal appear to also increase the risk of retinopathy of prematurity.[3-5] Oxygen toxicity may also increase the risk of mortality[6, 7], bronchopulmonary dysplasia[8-10], periventricular leukomalacia[11], cerebral palsy[12], and other morbidities. Although a multicenter study [13] could not determine an association between oxygen levels and retinopathy, a single center cohort study using transcutaneous oxygen monitoring supported the association of retinopathy with exposure to arterial oxygen levels $\geq$ 80mmHg.[14]

The recent introduction of pulse oximeters into the neonatal intensive care units, have allowed clinicians to utilize oxygen saturations to target oxygenation in premature infants. A survey study of 144 neonatal intensive care units conducted in 2001, revealed that the average lower limit of target oxygen saturations was 90% and the upper limit was 96%.[5] In recent years, the use of high saturation targets has been associated with the increased risk for retinopathy. The rate of retinal ablation surgery was higher at neonatal intensive care units with maximal target oxygen saturation $\geq$ 98% (5.6 $\pm$ 1.1 versus 3.1 $\pm$ 0.3%) or $\geq$ 92% (3.3 $\pm$ 0.3 versus 1.4 $\pm$ 0.2%).[5] Recent studies suggest that oxygen saturation targeting from the first day after birth at levels lower than previously used may reduce the incidence of retinopathy. In a retrospective study comparing outcomes at five neonatal intensive care units, the incidence of severe

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

retinopathy requiring ablation therapy was 27% in units where target saturations were 88 to 98% and only 6% in units where the target was 70 to 90%.[3] Rates of mortality and cerebral palsy did not differ in these units. In three other studies, a policy of oxygen saturation targeting of approximately 83 to 95% resulted in a substantial reduction in retinopathy.[4, 15, 16] However, in these studies, actual oxygen saturations achieved were not reported. Pulse oximetry has become the standard technique for continuous monitoring of oxygenation. While data from recent prospective observational and retrospective studies[3, 4, 15-19] suggest that maintenance of oxygenation at ranges lower than previously used may decrease the incidence of retinopathy of prematurity, there is no conclusive evidence that these oxygenation levels do so without an increase in serious adverse effects.

We conducted a 2 x 2 factorial-design multicenter randomized trial of oxygen saturation targeting, testing the effect of a lower oxygen saturation range (85-89%) as compared to a higher oxygen saturation range (91-95%) on the incidence of threshold retinopathy of prematurity, eye surgery for retinopathy, and/or death among infants of 24 to 27 weeks gestational age at birth. The factorial design allowed comparison of prophylactic/early surfactant versus continuous positive airway pressure; thus, controlling for the approach to ventilatory support.

METHODS

The institutional review boards at all Neonatal Research Network clinical centers and at Research Triangle International (data center) approved the trial. Written informed consent was obtained from the parent or guardian of each participant before delivery.

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

Patients

Infants of $24^{0/7}$ to $27^{6/7}$ weeks gestational age, without a decision to forgo support were eligible for enrollment at birth. Exclusion criteria were outborn infants and major congenital anomalies. Multiple births were randomized to the same arm of the trial.

Enrollment and treatment

Infants were stratified by center and by gestational age ($24^{0/7}$ to $25^{6/7}$ weeks or $26^{0/7}$ to $27^{6/7}$ weeks). Infants were randomly assigned by means of double-sealed envelopes to oxygen saturation targeting of 85 to 89% or 91 to 95%. Masking was maintained using electronically-altered pulse oximeters with output display of 88 to 92% for these oxygen ranges, an offset of 3% as previously used to separate oxygen saturations in premature infants.[20] Participants were also randomly assigned to respiratory support using either prophylactic/early surfactant with conventional ventilation management or to continuous positive airway pressure with a permissive ventilatory strategy. The oxygen saturation values displayed reverted to actual values when less than 85% or greater than 95%. Oxygen saturation targeting with the altered pulse oximetry was initiated within the first two hours after birth and was continued until 36 weeks post-menstrual age or until the infant remained on room air and off the ventilator/continuous positive airway pressure for more than 72 hours. Infants weaned to room air but who subsequently received oxygen supplementation before 36 weeks post-menstrual age were placed back on the assigned study pulse oximetry. Adjustments in supplemental oxygen to target oxygen saturations were performed by the clinicians, not by the research staff.

Assessments

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

Research nurses recorded all data using standardized definitions. Data were collected until discharge or 120 days postnatal age whichever occurred first. Threshold retinopathy of prematurity (New Type 1 threshold per Early Treatment of Retinopathy [ETROP] Cooperative Group[21]) was coded if any of the following four findings were present up to 55 weeks post-menstrual age:

If in zone 1: Stage 3 retinopathy of prematurity, even without plus disease

Plus disease with any stage retinopathy of prematurity

If in zone II: Plus disease with stage 2 retinopathy of prematurity

Plus disease with stage 3 retinopathy of prematurity

Surgical intervention included laser therapy, cryotherapy, laser/cryotherapy, scleral buckle, and vitrectomy. Outcomes included predefined clinical diagnoses and potential adverse events.

Statistical analysis

The primary analysis of this factorial trial was a logistic regression analysis of the percentages of infants in each group (lower versus higher oxygen saturations) who developed the primary outcome. An absolute difference of 10% between the two treatment groups was considered clinically important. To detect this difference, we planned to enroll 1312 infants for 80% power and a baseline estimated rate of 45% of death/threshold retinopathy/surgery, based on an increase by a factor of 1.12 to account for randomizing multiples to the same treatment group and on an increase by a factor of 1.17 to account for the expected attrition after discharge and before follow up. The trial was not powered to determine an interaction between the two interventions. Intention-to-treat analyses were performed. The denominator used to calculate the rate of each outcome was the number of infants for whom that outcome was known. Analyses were conducted by the data center. A two-sided P value of less than 0.05 was considered to be statistically significant. Analyses did not include adjustment for multiple comparisons.

An independent data safety and monitoring committee reviewed the primary outcomes, adverse events, and other interim results at ~25%, 50%, and 75% of planned enrollment. Pocock boundaries were used to develop stopping rules for interim safety monitoring.

RESULTS

1316 infants were enrolled between January 2004 and March 2009 (Figure 1). Enrollment was temporarily stopped by the Data Safety and Monitoring Committee because of concerns regarding compliance with oxygen saturation targets. Separate of analysis of the oximetry data while on room air versus while on oxygen supplementation resolved the concerns. The baseline characteristics of the lower saturation group and the higher saturation group were similar (Table 1).

Major outcomes

The Data Safety and Monitoring Committee masked interim analyses were made available to the investigators after enrollment was completed. There had been a trend for increased mortality in one of the treatment groups that had not reached the stopping boundary. The principal investigator and data center staff undertook a safety analysis to evaluate potential adverse outcomes without unblinding the retinopathy outcome data. This manuscript reports the hospital outcomes. Retinopathy and 18-22 month follow up outcomes will be reported later.

Mortality at any time during hospitalization occurred in 130 of the 655 (20%) of the infants in the lower oxygen saturation group versus in 106 of the 661 (16%) of the infants in the higher oxygen saturation group (RR 0.78, CI 0.62, 0.99, P=0.04). Comparable results were observed in both gestational age groups used for stratification. Mortality in the first and second weeks after birth was comparable in the

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

two groups (Table 2). Other prespecified major outcomes were comparable between the two treatment groups (Table 2).

The median oxygen saturation of both groups differed substantially but, as expected, there was some overlap (Figure 2). These data indicate that actual oxygen saturation levels are slightly higher than targets in both treatment groups. The duration of oxygen supplementation was shorter in the lower oxygen saturation group but the duration of mechanical ventilation, continuous positive airway pressure, and nasal synchronized intermittent mandatory ventilation did not differ (Table 3). Other measures of resource utilization did not differ.

DISCUSSION

The recommended ranges of oxygen saturation targeting for very preterm infants have been determined from nonrandomized studies and restriction of oxygen supplementation is becoming the standard practice.[3, 22] However, there was an increase in mortality when a restrictive oxygen supplementation was practiced in the 1950s and 1960s. Despite now being based on randomized controlled trials and limited evidence of safety, lower oxygen saturation targeting has become the recommended. In the current trial, lower oxygen saturation targeting (85-89%) resulted in an increased risk of mortality.

This trial was not prospectively powered for a difference in mortality only between the two oxygen saturation groups and, thus, the results should be viewed with caution. However, this is the largest randomized trial to test the effect of lower versus higher oxygen saturation targeting and the results add to previous data raising the concern that oxygen restriction may increase mortality in very preterm

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

infants. The infants in this trial were more immature than those of any previous trails of oxygen restriction and, thus, may have had a higher susceptibility to the effects of lower oxygen saturation targeting. In addition, aside from the decreased use of oxygen supplementation at 36 weeks, there were no other benefits from oxygen restriction. The previous data on the increased mortality from oxygen restriction were from studies with lower level of evidence rather than randomized controlled trials, except for the trends in the 1950s which had a combined risk difference of 4.9% increase in mortality in the oxygen restricted group (Ref 1).

Restriction of oxygenation in the randomized controlled trials in preterm infants beyond the first weeks of life did not show trends for increased mortality in the lower saturation target groups.[17, 18] However, these trials aimed for saturations of 91 to 94% and 89 to 94% in the lower oxygen saturation group. Mortality in the current trial did not differ by 7 or 14 days. Therefore, the lower target of oxygen saturations rather than the postnatal age of the intervention may be related to the adverse outcome.

There are several ongoing trials that address the same intervention tested in the current trial as well as a planned prospective meta-analysis.[1] At the present time, it is important that these trials continue. It is also important that the investigators and the data safety and monitoring committees of these trials are aware of the results of the current trial so appropriate decisions can be made regarding their interim analyses, completion of the trials, and dissemination of the data. The current trial raises the concern of adverse hospital outcomes due to oxygen saturation targeting in the 85 to 89% range. Further information from the ongoing randomized controlled trials that evaluate lower versus higher oxygen saturation targeting will become available in the next years but at the present time, caution should be exercised regarding oxygen targeting in the low range tested in the current trial.

Subject: O2 Saturation Paper
Date: Tuesday, September 15, 2009 4:50:09 PM
Attachments: Oxygen Saturation Targeting.9.15.09.doc

Dear Rose, Neil, Marie, and Abhik:

Enclosed is draft 3 of the saturation paper. I have written as agreed (without the ROP data). The Results and Discussion are completely new. The Discussion is still in its first draft. I have completed Figure 1 (pending decision to drop completely the ROP data) and have modified Figure 2 from one of the figures Marie sent. I have used the median figure as it gives one value per baby so there is less bias due to babies on O2 for a prolonged period. Should we consider a survival plot as mortality did not differ on day 7 and may be a late occurrence? The references need formatting.

I think you may want to wait until we are closer to data lock.

Marie: I still need IVH/death and other outcomes (see Tables) as well as RR and CI.

Thanks for your help.
Wally

ABSTRACT

Background

Non randomized studies suggest that the incidence of retinopathy decreases in premature infants with exposure oxygenation levels lower than previously maintained. However, the range of oxygen saturations that reduces retinopathy without increasing adverse outcomes is not known.

Methods

1316 infants of 24 to 27 weeks gestation born at 20 centers of the Neonatal Research Network were randomly assigned at birth to oxygen saturation targets of 85 to 89% or 91 to 95%. The primary outcome was a composite of threshold retinopathy of prematurity, eye surgery for retinopathy, and/or death.

Results

Conclusions

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

INTRODUCTION

Retinopathy of prematurity remains an important cause of blindness and other visual disabilities among prematurely born infants. The incidence of retinopathy of prematurity increased with exposure to unrestricted oxygen in premature infants in randomized controlled trials performed in the 1950s.[1] However, the practice of restricting oxygen supplementation in subsequent years was estimated to result in an excess of 16 deaths per case of blindness prevented.[2] However, more recent data suggest that oxygen saturation levels previously thought to be in the upper limits of normal appear to increase the risk of retinopathy of prematurity.[3-5] Oxygen toxicity may also increase the risk of mortality[6, 7], bronchopulmonary dysplasia[8-10], periventricular leukomalacia[11], cerebral palsy[12], and other morbidities. Even though a multicenter study [13] could not determine an association between oxygen levels and retinopathy, a single center cohort study using transcutaneous oxygen monitoring supported the association retinopathy with exposure to oxygen levels $\geq$ 80mmHg.[14]

With the introduction of pulse oximeters, more recent data are based on oxygen saturations. A survey study of 144 neonatal intensive care units conducted in 2001, revealed that average target oxygen saturations had a low limit of 90% and an upper limit of 96%.[5] Use of high saturation targets may result in increased risk for retinopathy. The rate of retinal ablation surgery was higher at neonatal intensive care units with maximal target oxygen saturation $\geq$ 98% (5.6 $\pm$ 1.1 versus 3.1 $\pm$ 0.3%) or higher than 92% (3.3 $\pm$ 0.3 versus 1.4 $\pm$ 0.2%).[5] Recent studies suggest that oxygen saturation targeting from the first day after birth at levels lower than previously used may reduce the incidence of retinopathy. In a retrospective study comparing outcomes at five neonatal intensive care units, the incidence of retinopathy requiring ablation therapy was 27% in units where target saturations were 88 to 98% and 6%

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

in units where the target was 70 to 90%.[3] Rates of mortality and cerebral palsy did not differ in these units. In three other studies, a policy of oxygen saturation targeting of approximately 83 to 95% resulted in a substantial reduction in retinopathy.[4, 15, 16] However, actual oxygen saturations achieved were not reported. Pulse oximetry has become the standard technique for continuous monitoring of oxygenation. While data from recent prospective observational and retrospective studies[3, 4, 15-19] suggest that maintenance of oxygenation at ranges lower than previously used may decrease the incidence of retinopathy of prematurity, there is no conclusive evidence that these oxygenation levels can reduce retinopathy of prematurity without an increase in serious adverse effects.

We conducted a 2 x 2 factorial-design multicenter randomized trial of oxygen saturation targeting, testing the effect of a lower oxygen saturation range (85-89%) as compared to a higher oxygen saturation range (91-95%) on the incidence of threshold retinopathy of prematurity, eye surgery for retinopathy, and/or death among infants of 24 to 27 weeks gestational age at birth. The factorial design allowed comparison of prophylactic/early surfactant versus continuous positive airway pressure; thus, controlling for the approach to ventilatory support.

METHODS

The institutional review boards at all Neonatal Research Network clinical centers and at Research Triangle International (data center) approved the trial. Written informed consent was obtained from the parent or guardian of each participant before delivery.

Patients

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

Infants of $24^{0/7}$ to $27^{6/7}$ weeks without a decision to forgo support were eligible for enrollment at birth. Exclusion criteria were outborn infants and major congenital anomalies. Multiples were randomized to the same arm of the trial.

Enrollment and treatment

Infants were stratified by gestational age ($24^{0/7}$ to $25^{6/7}$ weeks or $26^{0/7}$ to $27^{6/7}$ weeks) and by center. Infants were randomly assigned by means of double-sealed envelopes to oxygen saturation targeting of 85 to 89% or 91 to 95% with masking using electronically-altered pulse oximeters with output display of 88 to 92% for these oxygen ranges, an offset of 3% as previously used to separate oxygen saturations in premature infants.[20] They were also randomly assigned to respiratory support using either prophylactic/early surfactant with conventional ventilation management or to continuous positive airway pressure with a permissive ventilatory strategy. The oxygen saturation values displayed reverted to actual values when less than 85% or greater than 95%. Saturation targeting was initiated within the first two hours after birth. Oxygen saturation targeting with the altered pulse oximetry was continued until 36 weeks post-menstrual age or until the infant remained on room air and off the ventilator/continuous positive airway pressure for more than 72 hours. Infants weaned to room air but who subsequently received oxygen supplementation before 36 weeks post-menstrual age were placed back on the assigned study pulse oximetry. Adjustments in supplemental oxygen to target oxygen saturations were performed by the clinicians, not by the research staff.

Assessments

Research nurses recorded all data using standardized definitions. Data were collected until discharge or 120 days postnatal age whichever occurred last. Threshold retinopathy of prematurity (New Type 1

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

threshold per Early Treatment of Retinopathy [ETROP] Cooperative Group[21]) was coded if any of the following four findings were present up to 55 weeks post-menstrual age:

If in zone 1: Stage 3 retinopathy of prematurity, even without plus disease

Plus disease with any stage retinopathy of prematurity

If in zone II: Plus disease with stage 2 retinopathy of prematurity

Plus disease with stage 3 retinopathy of prematurity

Surgical intervention included laser therapy, cryotherapy, laser/cryotherapy, scleral buckle, and vitrectomy. Outcomes included predefined clinical diagnoses and potential adverse events.

Statistical analysis

The primary analysis of this factorial trial was a logistic regression analysis of the percentages of infants in each group (lower versus higher oxygen saturations) who developed the primary outcome. An absolute difference of 10% between the two treatment groups was considered clinically important. To detect this difference, we planned to enroll 1312 infants for 80% power and a baseline estimated rate of 45% of death/threshold retinopathy/surgery, and based on an increase by a factor of 1.12 to account for randomizing multiples to the same treatment group and an increase by a factor of 1.17 to account for the expected attrition after discharge and before follow up. The trial was not powered to determine an interaction between the two interventions. Intention-to-treat analyses were performed. The denominator used to calculate the rate of each outcome was the number of infants for whom that outcome was known. Analyses were conducted by the staff at the data center. A two-sided P value of less than 0.05 was considered to statistically significant. Analyses did not include adjustment for multiple comparisons. An independent data safety and monitoring committee reviewed the primary outcomes,

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

adverse events, and other interim results at ~25%, 50%, and 75% of planned enrollment. Pocock boundaries were used to develop stopping rules for interim safety monitoring.

RESULTS

1316 infants were enrolled between January 2004 and March 2009 (Figure 1). Enrollment was temporarily stopped by the Data Safety and Monitoring Committee because of concerns regarding compliance with oxygen saturation targets. Separate of analysis of the oximetry data while on room air versus while on oxygen supplementation resolved the concerns. The baseline characteristics of the lower saturation group and the higher saturation group were similar (Table 1).

Major outcomes

The Data Safety and Monitoring Committee masked interim analyses were made available to the investigators after enrollment was completed. There had been a trend for increased mortality in one of the treatment groups that had not reached the stopping boundary. The principal investigator and data center staff undertook a safety analysis to evaluate potential adverse outcomes without unblinding the retinopathy outcome data. This manuscript reports the hospital outcomes. Retinopathy and 18-22 month follow up outcomes will be reported later.

Mortality at any time while hospitalized occurred in 130 of the 655 (20%) of the infants in the lower oxygen saturation group versus in 106 of the 661 (16%) of the infants in the higher oxygen saturation group (RR 0.78, CI 0.62, 0.99, P=0.04). Comparable results were observed in both gestational age groups used for stratification. Mortality in the first and second weeks after birth was comparable in the

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

two groups (Table 2). Other prespecified major outcomes were comparable between the two treatment groups (Table 2).

The median oxygen saturation of both groups differed substantially but, as expected, there was some overlap (Figure 2). These data indicate that actual oxygen saturation levels are slightly higher than targets in both treatment groups. The duration of oxygen supplementation was shorter in the lower oxygen saturation group but the duration of mechanical ventilation, continuous positive airway pressure, and nasal synchronized intermittent mandatory ventilation did not differ (Table 3). Other measures of resource utilization did not differ.

DISCUSSION

The ranges of oxygen saturation targeting recommended for very preterm infants have been determined from nonrandomized studies and restriction of oxygen supplementation is becoming the standard practice.[3, 22] However, there was an increase in mortality when a restrictive oxygen supplementation was practiced in the 1950s and 1960s. Lower oxygen saturation targeting has become the recommended even though this practice is not based on randomized controlled trials and there has been limited evidence of safety. In the current trial, lower oxygen saturation targeting (85-89%) resulted in an increased risk of mortality.

This trial was not powered for mortality only and thus caution should be exercised regarding the mortality data. However, this is a large multicenter trial and the results extend previous data raising the

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

concern that oxygen restriction may increase mortality in very preterm infants. The previous data were from studies with lower level of evidence rather than randomized controlled trials.

Restriction of oxygenation in the randomized controlled trials in preterm infants beyond the first weeks of life did not show trends for increased mortality in the lower saturation target groups.[17, 18] However, these trials aimed for saturations of 91 to 95% and 89 to 94% in the lower oxygen saturation group. Mortality in the current trial did not differ by 7 or 14 days so the lower target of oxygen saturations used rather than the postnatal age of the intervention may be related to the adverse outcome.

There are several ongoing trials that address the same intervention tested in the current trial as well as a planned prospective meta-analysis (ref). At the present time, it is important that these trials continue. It is also important that the investigators and the data safety and monitoring committees of these trials are aware of the results of the current trial so appropriate decisions can be made regarding their interim analyses, completion of the trials, and dissemination of the data. The current trial raises the concern of adverse hospital outcomes due to oxygen saturation targeting in the 85 to 89% range. While further data from the ongoing randomized controlled trials are available, caution should be exercised regarding oxygen targeting in this range.

5-min Apgar score < 3 – no. (%)	34/655 (5)	24/661 (4)
Surfactant – no.(%)	532/654 (81)	557/659 (85)

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

Table 2. Major Outcomes

Predischarge outcome – no./total no. (%)	Lower Saturation Group	Higher Saturation Group	Relative Risk (95% CI)
Death before discharge	130/655 (20)	106/661 (16)	
Death by 7 days	41/655 (6)	38/661 (6)	
Death by 14 days	64/655 (10)	56/661 (8)	
Bronchopulmonary dysplasia by O_2 use at 36 weeks*	203/541 (38)	262/567 (46)	
Bronchopulmonary dysplasia (O_2) or death by 36 weeks*	317/655 (48)	356/661 (54)	
Bronchopulmonary dysplasia (physiologic) at 36 weeks*	209/542 (39)	239/567 (42)	
Bronchopulmonary dysplasia (physiologic) or death by 36 weeks*	322/655 (49)	333/661 (50)	
Intraventricular hemorrhage, grade 3 or 4	95/632 (15)	87/639 (14)	
Intraventricular hemorrhage, grade 3 or 4 or death	188/655 (29)	161/660 (24)	
Periventricular leukomalacia	23/631 (4)	32/640 (5)	
Periventricular leukomalacia or death	148/654 (23)	133/661 (20)	
Necrotizing enterocolitis, stage ≥ 2	76/642 (12)	70/648 (11)	
Necrotizing enterocolitis, stage ≥ 2 or death	176/655 (27)	155/661 (23)	
Late onset sepsis	228/625 (36)	227/633 (36)	
Late onset sepsis or death	301/655 (46)	291/661 (44)	
Patent ductus arteriosus	308/642 (48)	323/647 (50)	
Medical treatment for patent ductus arteriosus	220/635 (35)	232/644 (36)	
Surgical treatment for patent ductus arteriosus	73/642 (11)	68/647 (11)	
Pneumothorax – no. (%)	48/655 (7)	43/661 (7)	
Any air leaks – no. (%)	50/655 (8)	43/661 (7)

Subject: Duke Site Visit (Monitoring) Report
Date: Tuesday, September 15, 2009 4:26:16 PM
Attachments: Support Monitor Report Duke 20090915.doc

Hi Rose,

Please find attached our final draft of the Duke Monitoring trip report. I focused solely on the data monitoring and regulatory rather than any of the communications or lack of processes in place to bring things up to speed because I believe that will be covered in the trip on the 29th .

Thanks and please let me know if you have any questions or require any edits.

SITE MONITORING TRIP REPORT

Trial Name:	The SUrfactant Positive Airway Pressure and Pulse Oximetry Trial in Extremely Low Birth Weight Infants The SUPPORT Trial
Site Number:	19
Site Name:	Duke University
Investigator Name:	Ronald Goldberg MD
Prior Monitoring Visits:	December 3, 2002; March 19, 2008
Date(s) of This Visit:	September 2 & 3, 2009

Monitor Name: Kristin Zaterka-Baxter, RN
Other Non-Site Personnel in Attendance: Jeanette Auman, B.S Amanda Irene, B.S Jamie Newman, PhD Carolyn Huitema, M.S.
Site Personnel in Attendance: Ronald Goldberg, MD Michael Cotton, MD Kimberly Fischer, PhD Stephanie Crosby, LPN Charles Vajdl

Monitoring Summary:

Monitoring of primary study outcomes (ROP, BPD, 18-22M Follow Up) was incomplete due to lack of source documentation and was overall unsuccessful due to more than three of the 15 cases determined to have one or more data inconsistencies.

- ROP source documents were missing or incomplete for 11 of the 15 cases reviewed. There were at least 2 inconsistencies reported for final ROP status based on source document review.
- BPD data was available though found to be inconsistent with source documents in several cases. In at least 4 cases BPD queries were generated for incomplete data on the Supp11 because these infants were transferred to Durham Regional Hospital (DRH) prior to 36 weeks and no further data was collected. However, final status per the GDB was documented as discharged to home after 36 weeks; it is unclear whether DRH is a participating site and whether Duke can obtain data from DRH.
- There are no outstanding issues with Follow-Up for the cases reviewed. The follow up rate for both Support and GDB averages 93%.

Data edits were reviewed by the RTI Data Manager with the Duke staff. Most of the outstanding data edits for Support were resolved within this 2 hour window of review. Edits are repeatedly reported from month to month because they are not being resolved expeditiously; noted that there are a minimal number of Support edits.

The Regulatory process at Duke is quite involved with numerous (5) levels of review prior to approval. Average time from submission to approval is 2 months. All recent studies have been submitted or approved. There is a detailed audit trail from submission to approval available for each study. There were a few informed consents for the Breathing Outcomes secondary study that were not readily available for review and 2 incomplete Support consent forms specifically for the embedded opt-in/opt-out Neuroimaging and Neurodevelopmental secondary study option.

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

A. Regulatory Oversight

1. Local regulatory oversight adherence ☑ Yes ☐ No
- IRB Submission and approval adequately documented

- Detailed outline and discussion regarding regulatory processes for NIH approved studies recommended to enhance timely protocol approvals.

In brief; five levels of review are required before a study can start at Duke.
-Department Administrator
-Department Chair review
-Departmental IRB review
-Pediatric Risk Assessment review
-Full IRB review

Protocol	Study Approved for IRB Submission	Date of Submission to Local IRB	IRB Final Approval	Expires
GDB		3/23/2009	5/5/2009	5/19/2010
GDB Follow Up		2/26/2009	3/31/2009	4/21/2010
SUPPORT		2/10/2009	3/11/2009	4/7/2010
Term Hypotension		4/20/2009	5/28/2009	5/28/2010
Preemie aEEG	5/21/2009	6/4/2009	8/7/2009	8/7/2010
Early BP	5/21/2009	6/11/2009	Pending	
Late Hypothermia		4/2/2009	5/14/2009	5/29/2010
Extended Hypo FU		10/21/2008	11/18/2008	12/14/2009

All studies approved have current IRB approval. The regulatory binder presented did not have the following current documents:

Protocol	Items Missing
GDB	consent form in English technical memos (18, 29, 20, 23)
GDB Follow Up	consent form in English, Manual of operations technical memos (21, 33, 34)
SUPPORT	consent form
Growth:	protocol
Breathing Outcomes:	consent eventually rolled into primary
Neuroimaging:	Manual of operations consent eventually rolled into primary
Term Hypotension	Manual of operations
Preemie aEEG	Technical memo (1)
Early BP	*pending IRB approval*
Late Hypothermia	Manual of operations IRB approval Consent form technical memo (2)
Extended Hypo FU	consent form

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

B. Cases Reviewed:

CENTER	NETWORK	DOB
19	69841	09/07/2005
19	69871	09/16/2005
19	69971	09/30/2005
19	71681	11/28/2006
19	72361	06/06/2007
19	72362	06/06/2007
19	72541	05/21/2007
19	72892	09/26/2007
19	72911	10/01/2007
19	72981	10/27/2007
19	72982	10/27/2007
19	73981	11/29/2008
19	74031	12/22/2008
19	74032	12/22/2008
19	74131	01/18/2009

C. General Study Conduct

1. The Investigator is adhering to the protocol and amendments ☑ Yes ☐ No
- All subjects reviewed were randomized and delivered the assigned intervention however based on randomization number however, 2 cases reviewed were missing the actual randomization cards to verify the site used the correct randomization number.
- All subjects reviewed followed intervention guidelines per treatment arm and protocol.

2. Subject eligibility ☑ Yes ☐ No
- All subject that were reviewed appeared to be eligible for study however, of the 15 cases, 4 medical record charts were incomplete or unavailable for source documentation (69971, 74031, 74032, 73981)

D. Data Management

Support Study Data Collection

1. Case Report Forms (CRFs) reviewed against source documentation ☑ Yes ☐No
CRFs were reviewed where source documentation was provided

2. Source documentation adequate to support entries on CRFs ☐ Yes ☑No
Many source documents were not available at the time of review. There was an adoption of electronic medical records in 2008 though neither the electronic records nor paper medical records contained complete source documentation.

Several data inconsistencies noted when reviewed against available source documents (as outlined below).

3. Timely data entry ☐ Yes ☑ No
Upon random review of the Support data entry one infant was identified as being enrolled to study on 03/26/07; no data was entered until 09/02/09 (ID 74261) post completion of recruitment.

4. Timely resolution of edits ☐ Yes ☑No
- As of the most recent SUMMARY OF MISSING SUPPORT FORMS report posted to the NRN website (09/05/09), 30 out of a total of 64 missing forms cross centers belonged to Duke, the Supp05 forms had the

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

highest number missing (N17). The average of missing Support forms cross centers is 3 (range 0-8).

- Within the batch edits posted to the NRN website there are a minimal number of edited reported however, over the past 3 months, an average of 80% of these edits have been unresolved and repeated from month to month.

5. Deviations Noted ☑ Yes ☐ No

- Infant (74131) withdrawn from study per physician decision due to unblinding of the oximetery arm on DOL 51. Protocol Deviation form SUPP09 completed 03/26/09 however there is no documentation of informing NICHD or RTI of withdrawal and no source documentation of withdrawal or parental notification of withdrawal in medical or research records. Discussion of this case and whether the data can be used is pending.

E. Secondary Studies Data Collection

1. Object Permanence Ancillary (MRI09A form completed appropriately for eligible subject) ☐ Yes ☑ No
Jamie Newman, RTI Follow-up Coordinator, reviewed the Monthly Report table and accompanying list of eligible patients posted to the site specific portion of the NRN website with Dr. Kim Fisher. Out of 18 patients enrolled in the Neurodevelopmental Outcomes Secondary to SUPPORT, 5 patients are currently expected for the Object Permanence Ancillary (pts that have already been seen for 18 month Follow-up and have a Bayley III exam). No MRI09A forms have been keyed to date. Jamie will also address this with the Bayley examiner, Dr. Katie Gustafson. Duke is well positioned for moving forward with this study since the windows are just starting to open. They should be able to collect these additional Bayely III items (items 40, 45, 50) prospectively for the remainder of their patients. Whether the additional Bayley III items can be collected from the original Bayley III score form for the 5 patients that have already been seen for follow-up will be discussed with the Bayley examiner.

2. Tracking for SUPPORT School Age (SEF01 form completed appropriately for eligible subjects) ☐ Yes ☑ No

Out of 12 patients with a successful MRI for the Neurodevelopmental Outcomes Secondary to SUPPORT, only 1 patient is currently expected to have an SEF01 form keyed, which is the 3-4 year tracking form. However, Duke is well positioned for moving forward with tracking for this study since the 3-4 year tracking windows are just starting to open. Tracking tools and open window reports can be printed from the Network computer.

3. Breathing Outcomes questionnaires completed appropriately for eligible subject) ☐ Yes ☑ No
Duke does the discharge interviews face-to-face and Rochester conducts the 6, 12, and 18 month interviews. All SUPPORT/Breathing Outcomes patients have been discharged. During staff turnover (coordinators) at Duke there may have been delays in getting contact information to Rochester for conducting the interviews which may have contributed to the missing 6 months interviews (all 6 month interviews). Because Breathing Outcomes interviews can not be done out of window, making sure Rochester has contact information for remaining interviews will need to be done.

Breathing Outcomes eligible patients that are missing Breathing Outcomes consent forms needs to be further investigated (perhaps not all of the patient's file was given to us?). One possibility is that the family refused and the enrollment log (SUPF00) has not been keyed to indicate this. This is where the coordinator/keyer indicates that patient refused consent. (consent granted = 2 NO or 3 refused).

The enrollment log is located on the NRN website:
Protocols – SUPPORT – Secondary Studies – Breathing Outcomes – Forms – SUPF00 (Enrollment Log)
This will be the first page that appears when the keyer begins to key Breathing Outcomes data. Once patients that refuse have been keyed on the enrollment log, they will no longer appear on the Breathing Outcomes Interview Schedule Report.

4. Neuroimaging and Neurodevelopmental Outcomes form MRI01 completed appropriately for eligible subject and required images sent to RTI. ☐ Yes ☑ No
Several MRI01 forms are outstanding; this form is to be completed regardless of whether this infant in enrolled to

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

the secondary. For the MRI01 forms completed, the majority of the previous data inconsistencies have been resolved prior to the monitoring visit. There remain 2 outstanding MRI images that should be sent to RTI as soon as possible (ID 72101, 72051)

5. SUPPORT Follow-up ☑ Yes ☐ No
Duke has a high SUPPORT Follow-up rate of 92.59% (based on form completion as well as official follow-up rate). Out of 27 SUPPORT patients currently expected for follow-up, 25 patients have completed follow-up, 2 patients have died after discharge and 2 patients are lost-to-follow-up. No inappropriate form completion was noted.

6. GDB Follow-up ☑ Yes ☐ No
Duke has a high GDB Follow-up rate of 93.33% (based on form completion as well as official follow-up rate). Out of 30 patients currently expected for follow-up, 28 patients have completed follow-up, 1 patient is lost-to-follow-up, and 1 patient is pending. No inappropriate form completion was noted.

7. Antenatal Secondary study ☐ Yes ☐ No ☑ NA
Data on this study was not reviewed

8. Growth Outcomes Secondary study ☐ Yes ☐ No ☑ NA
Data on this study was not reviewed

F. List issues that require follow-up

1. Verification of all Support Trial primary outcome data (64 cases) is requested.
2. Resolution of all Support Trial data edits and inconsistencies is requested: all edits/inconsistencies reported below, all edits posted to the NRN site specific website; all recent BPD queries; all recent Cross-Forms queries.
3. Confirmation of ancillary site participation for the following sites is requested: Durham Regional Hospital (DRH); Raleigh Duke Health; Alamance Regional Medical Center
4. Regulatory follow-up; Duke should track and maintain all study approvals and approved consent forms where applicable and submit these to RTI/NICHD as soon as approval is granted (including all satellite site approvals and approved consents were applicable).
    a. Follow up regarding unavailable or inappropriate MRI and Breathing outcomes consent is requested.
5. Standard Operating Procedures should be developed and adhered to for; data QA/QC; edit resolution; ancillary site communication, regulatory affairs process and procedures; protocol and data management training.
6. Follow-up with Rochester regarding the Support Secondary Breathing Outcomes eligible study subjects is recommended.

G. Case Audit

1. Patient NRN ID 6984-1

a. Consent

1. GDB enrolled?	✓ Yes ☐ No
1a. GDB consent signed	✓ Yes ☐ No
2. SUPPORT primary enrolled?	✓ Yes ☐ No
2a. SUPPORT primary consent signed	✓ Yes ☐ No
3. SUPPORT Growth enrolled?	☐ Yes ✓ No
3a. SUPPORT Growth consent signed	☐ Yes ☐ No ✓ NA

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

4. SUPPORT Breathing Outcomes enrolled? ✓ Yes ☐ No
4a. SUPPORT Breathing Outcomes consent signed ✓ Yes ☐ No ☐ NA

5. SUPPORT Neuroimaging enrolled? ☐ Yes ✓ No
5a. SUPPORT Neuroimaging consent signed ☐ Yes ☐ No ✓ NA

6. Follow Up window open? ✓ Yes ☐ No
6a. Follow Up consent signed ✓ Yes ☐ No ☐ NA

b. ROP Outcome

1. Were all eye exams available for review? ☐ Yes ✓ No
2. Were there any problems with the eye exams? ✓ Yes ☐ No
   a. If yes, explain

issues with ROP exam dates not matching dates on Supp10 form

Subsequent medical review of ROP data will be conducted by the NICHD Program officer.

c. BPD Outcome

1. Were all pertinent data available for review? ☐ Yes ✓ No
2. Were there any problems with the data? ✓ Yes ☐ No
   a. If yes, explain

d/c to DRH 11/15/05- status d/c to home 12/12 – cannot verify BPD outcome

d. Other

- checked for eligibility and protocol procedure; no issues
-Need copy of dc summary

2. Patient NRN ID 6987-1

a. Consent

1. GDB enrolled? ✓ Yes ☐ No
1a. GDB consent signed ✓ Yes ☐ No
(witness unrelated to study section not signed)
2. SUPPORT primary enrolled? ✓ Yes ☐ No
2a. SUPPORT primary consent signed ✓ Yes ☐ No

3. SUPPORT Growth enrolled? ☐ Yes ✓ No
3a. SUPPORT Growth consent signed ☐ Yes ☐ No ✓ NA

4. SUPPORT Breathing Outcomes enrolled? ☐ Yes ✓No
4a. SUPPORT Breathing Outcomes consent signed ☐ Yes ☐ No ✓ NA

5. SUPPORT Neuroimaging enrolled? ☐ Yes ✓ No
5a. SUPPORT Neuroimaging consent signed ☐ Yes ☐ No ✓ NA

6. Follow Up window open/closed? ✓ Yes ☐ No
6a. Follow Up consent signed ✓ Yes ☐ No ☐ NA

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

b. ROP Outcome

1. Were all eye exams available for review? ✓ Yes ☐ No
2. Were there any problems with the eye exams? ☐ Yes ✓ No
   a. If yes, explain

Subsequent medical review of ROP data will be conducted by the NICHD Program officer.

c. BPD Outcome

1. Were all pertinent data available for review? ☐ Yes ✓ No
2. Were there any problems with the data? ✓ Yes ☐ No
   a. If yes, explain

d/c to DRH 11/07/05- status d/c to home 12/02 – cannot verify BPD outcome

d. Other

- Checked for eligibility and protocol procedure; no issues
-Need copy of dc summary
-No note in comp with 11/7/05-dc from Duke to DRH on 11/7/05 but per NG03, status=DC to home 12/2/05. Do have SUPP11 data from DRH

3. Patient NRN ID 6997-1

a. Consent

1. GDB enrolled? ✓ Yes ☐ No
1a. GDB consent signed ✓ Yes ☐ No
did not check section with question pertaining to being contacted @18 months, baby died
2. SUPPORT primary enrolled? ✓ Yes ☐ No
2a. SUPPORT primary consent signed ✓ Yes ☐ No

3. SUPPORT Growth enrolled? ☐ Yes ✓ No
3a. SUPPORT Growth consent signed ☐ Yes ☐ No ✓ NA

4. SUPPORT Breathing Outcomes enrolled? ✓ Yes ☐ No
4a. SUPPORT Breathing Outcomes consent signed ☐ Yes ✓ No ☐ NA
Listed as Enrolled in the DMS but perhaps site failed to enter infant as "Consent Not Granted" on SUPF00
5. SUPPORT Neuroimaging enrolled? ☐ Yes ✓ No
5a. SUPPORT Neuroimaging consent signed ☐ Yes ☐ No ✓ NA

6. Follow Up window open/closed? ✓ Yes ☐ No
6a. Follow Up consent signed ☐ Yes ☐ No ✓ NA
baby died

b. ROP Outcome

1. Were all eye exams available for review? ☐ Yes ✓No
2. Were there any problems with the eye exams? ✓ Yes ☐ No
   a. If yes, explain

Missing 6 ROP exam reports

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

Subsequent medical review of ROP data will be conducted by the NICHD Program officer.

c. BPD Outcome

1. Were all pertinent data available for review? ☐ Yes ✓ No
2. Were there any problems with the data? ✓ Yes ☐ No
   a. If yes, explain

- has NICU discharge summary but not detailed enough
- BPD 36wk support verified, no BPD

d. Other

No SUPP02 entered
This infant died 2/21/2006, after discharge

Hi Rose

I forgot to cc you on this when I sent to Kris. Basically just getting all our ducks in a row for data entry for SUPPORT MRIs. I sent off a batch of completed MRI's to Kris on Friday - but the reading process is SLOW going! I see many 6 am readings in my future stretching out for months to come...

Susan

> Hi Kris and Pat,
>
> Attached are the COMMENTS_ISSUES document (Pat we have talked about these changes and issues, but I have embedded a few additional questions for you - of course we will be seeing each other in early AM hours this week so we can go over it then if you want), and the revised KEY.
>
> Kris, I am sorry this took me a while! You are very patient. As you can see, it is the great American novel (or at least a short story), but I am very sure that I have not made myself too clear in parts. However, you are amazing and a mind reader, so you may understand my ramblings. Please call or email if you are scratching your head, and also if you have questions about MY questions to you!
>
> THANK YOU!!!

SUPPORT Neuroimaging:
COMMENTS/CLARIFICATIONS on MRI central reader FORM/KEY (SRH) *September 8, 2009*

These comments/corrections will follow the order of the MRI03 form as closely as possible, and are based on findings from multiple readings with Dr. Barnes. **These comments also incorporate previous comments from the June 29th reading.**

Note that the yellow highlighted are changes/corrections made to the key in June (sent previously, reiterated here); those in **blue font** are changes/corrections/additions made after the last 2 weeks of reading; and in [redacted] are comments/questions to Kris Zaterka. I have also inserted comments using "Track Changes" for Dr. Barnes.

1) **SECTION A (HEADER):**
   a. A. 5-13 (sequences and views)
      i. If a sequence is NOT circled "Yes", then it means "No" = those images are NOT present.
         1. For instance: If NOTHING is circled under coronal images on any line 5-9, then NO coronal images are present on the MRI
         2. If I am there with Dr. Barnes, I will do my best to circle the "no", but if Dr. Barnes is reading without me, it will likely NOT be circled.
         3. Clarification on sequences evaluated for Signal Abnormalities:
            a. If SPGR or "Ax-Flash" is available, that sequence may be reviewed as the preferred T1 sequence. This sequence may be more sensitive than "traditional" T1, and it is performed increasingly frequently in recent years.
   b. A. 14 (OTHER)
      i. Any other sequences obtained will be noted here. There are a few specific issues that have come up regarding sequences obtained from some of the sites that will be noted here:
         1. "T2=SSFSE": This means that the T2 sequence obtained was actually a single shot fast spin echo (SSFSE). T2 will still be circled YES, but the SSFSE will mean that Dr. Barnes cannot make a determination as to myelination by T2 (C.2.a) and it will be marked "not evaluable" in that section.
         2. "Proton Density" – Center 16 seems to get these a lot, at least early on (pre-2008)
2) **SECTION B (SIGNAL ABNORMALITIES):**
   a. **REGION, SITE**
      i. EPENDYMAL sub-site code: Under "Cerebral", there is now the addition of "ependymal" under each SITE (see yellow highlighted).

REGION	***CODE***	***SITE***		***CODE***
CEREBRAL	C	Frontal	cortical	FC
			subcortical	FSC

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

			periventricular	FPV
			ependymal	**FEP**
		Temporal	cortical	TC
			subcortical	TSC
			periventricular	TPV
			ependymal	**TEP**
		Parietal	cortical	PC
			subcortical	PSC
			periventricular	PPV
			ependymal	**PEP**
		Occipital	cortical	OC
			subcortical	OSC
			periventricular	OPV
			ependymal	**OEP**

1. **EPENDYMAL** lesions should NOT be coded GM or WM – they should be left blank (or with line through the GM/WM cell associated with that lesion). If Dr. Barnes thinks a lesion is definitely a WM or GM lesion, **they should be coded differently in terms of site and sub-site** (i.e., as periventricular, cortical, etc).
    a. **Therefore, if a lesion is coded as EPENDYMAL sub-site and GM or WM is coded, this should be flagged.**
2. **EPENDYMAL** lesions will most likely be coded as TYPE = hemorrhagic or mineralization (HEM/MIN). These are likely to represent subependymal hemorrhage or previous IVH in evolution.
3. A new code (see below) has been added for FOCAL/DIFFUSE cell which is **multifocal linear (MFL)**. This code will almost exclusively be used in conjunction with **EPENDYMAL** lesions, will be associated with multiple sub-sites (i.e., FEP, TEP, PEP, OEP), and will be TYPE=HEM/MIN. These lesions are basically mineralization or resolving hemorrhage lining the ependyma around multiple regions around the ventricle. Again, they probably represent subependymal hemorrhage or previous IVH in evolution.

[redacted]

b. SIDE

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

i. If I am with Dr. Barnes, I try my best to code lesions as separate lesions, even if similar lesions appear on R and L (i.e., same lesion description for R and L side, entered as lesion #1 and lesion #2). However, if Dr. Barnes is reading without me, he may use his shorthand (as with the Hypothermia MRIs) and write R/L in the SIDE cell associated with the lesion. This will mean that the lesion described is on the RIGHT and LEFT side (i.e., two lesions).

c. **T1, T2, FL, GRE, DWI, ADC**
   i. If the cell is left **blank**, it means it cannot be seen on that sequence = ISOINTENSE or I.
      1. [redacted]
   ii. However, NOTE that the cell may be left blank also if that sequence was NOT DONE! So, the programmers/data entry folks should know that they shouldn't just replace a blank cell with "I" code. [redacted]
   iii. Note that I have removed the line in the KEY that says "If lesion no seen on sequence, code "98" or if sequence not done, code"99".

d. **Focal/Diffuse**
   i. As noted above a new code needs to be added for FOCAL/DIFFUSE cell which is **multifocal linear (MFL)**. This code will almost exclusively be used in conjunction with **EPENDYMAL** lesions, will be associated with multiple sub-sites (i.e., FEP, TEP, PEP, OEP).
   ii. FP = focal punctate. The lesion is 1 mm or less in diameter
   iii. FL = focal linear.
   iv. FN = focal nodular
   v. D = diffuse. [I doubt this will be used too much. It is very hard to QUANTITATE a diffuse lesion.]
   vi. MF = multifocal nodular. Multiple scattered nodular lesions.

e. **GM/WM**
   i. When I am with Dr. Barnes during the reading, I am trying to be AS CLEAR as possible about whether a lesion is GM or WM – if there are lesions in both GM and WM, I do my best to make sure to mark them separately. However, if Dr. Barnes is reading alone, **he may mark GM/WM and it means that both WM and GM are involved in the area of injury**.
   ii. If the lesion cannot be classified as EITHER WM or GM, it should be left blank or with a line through that cell. This should really only occur with a limited number of sites –
      1. EPENDYMAL lesions as described above,
      2. VENT lesions

Comment [SH1]: PAT: Do you agree with this? For instance, I find the whole "DEHSI" issue a bit difficult to sort out unless all imaging is done in the same place with exactly the same protocol

Comment [SH2]: PAT: Please review this section of comments pertaining to GM/WM column of the Signal Abnormalities section of the form. Is this all correct from your perspective?

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

3. *There may be others, but I can't think of any at the moment!*

f. **SIZE**
   i. Size will be entered in millimeters (i.e., 3 = 3 mm).
   ii. For FP, 1 will be entered. (See section d above).
   iii. If the lesion is FN, the diameter of will be entered. If multifocal nodular (MF), the diameter of the largest lesion will be entered. If focal linear, this will mean that the diameter is 1 mm or less and the LENGTH of the lesion will be entered. **For MFL, the SIZE CELL will be left blank** because MFL will mean the lesion spans over several sub-site areas. In any case, as noted above, the MFL code will be used probably almost exclusively for the ependymal Hem/Min lesions.

g. **TYPE**
   i. See Key.
   ii. If a lesion is CYSTIC, and it appears to be a porencephalic cyst, **the lesion # should be referenced and this should be noted on page 1 (in the blank space under the signal abnormalities grid) or in the COMMENTS at the end of the form.**
   [redacted]
   iii. NOTE: Some lesions are marked HEM/MIN. It is difficult to know whether it is actually blood or mineralization. This is especially true for those lesions only seen on GRE.
   iv. [redacted]analysis
   v. Also, the HEM/MIN or NCYS lesions that are seen ONLY on GRE (i.e., isointense in all other sequences) may need to be broken out in analysis separately at some point in analysis.

Comment [SH3]: Pat: I would suspect you would agree with this statement and the one following (g.iv). It may not be possible for you to distinguish hemorrhage from mineralization, and in any case, these are near-term infants – the likelihood that there is true active hemorrhage I would think is remote.

3) **SECTION C. MATURATION AND DEVELOPMENT**

a. **C 1. GRAY MATTER**

Dr. Barnes' experience, coupled with the brain MRI's reviewed thus far from this extremely preterm SUPPORT cohort, have revealed a concerning and more delayed than anticipated cortical maturational pattern. This has been noted in previous literature (Inder 2003), with very limited number of extremely preterm patients. Furthermore, previous literature has only recorded only *broad maturation categories of up to 3-5 week PMA* (Woodward 2005, Huppi 1996, Childs 2001) based on the best available developmental data from 1970's and 1980's (Chi 1977, McArdle 1987, Martin 1988). It is therefore likely that the description of the SUPPORT MRI cohort cortical maturational pattern will bring important new information to the literature. It is therefore important to parse the cortical gray matter maturation as carefully as possible.

   i. Therefore, **"G 2.5" and "G 3.5" categories have been added** because the original stages and previous descriptions in the literature were simply too far apart and did not encompass the finer level of detail in maturational changes that have been seen. See revised KEY below.

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

***C.1. GRAY MATTER MATURATION* (ref. 1-3, 8-10)**	
Stage	***C.1.a. Cortical maturation markers***
G0	Frontal and occipital cortex completely smooth, insula widely open
G1	Frontal cortex still smooth, but some sulci in occipital cortex
G2	Frontal and occipital cortex with some convolutions, frontal sulci shallow. Internal surface of insula more convoluted.
G 2.5	**All G2 markers, approaching G3 - however, secondary gyri are not present in all areas as noted in G3**
G3	Presence of marginal sulcus and paracentral gyrus. Frontal and occipital cortex folded and richer in sulci. Insula more convoluted and infolded. Secondary gyri present in frontal, superior and middle temporal, pre- and post-rolandic, insula, occipital
G 3.5	**All G3 markers, approaching G4 – secondary gyri of G4 present, but anterior and posterior orbital gyri may not be established**
G4	Secondary gyri present transverse and inferior temporal; Anterior and posterior orbit gyri should be established.
G5	Teritiary inferior temporal and inferior occipital gyri and sulci present. White matter now isointense with gray matter on T1
NE	Not Evaluable

b. C.2.a WHITE MATTER Markers of myelination

i. As noted above (section 1.b.i.1), T2 will be marked Not Evaluable in cases where T2 was obtained by SSFSE

ii. As described in the June 29th changes, clarification as to the myelination pattern was necessary. The revised definition recognizes the need for more detailed white matter maturation pattern based on completeness of PLIC myelination at this postmenstrual age range. This is consistent with the literature. The following has been changed in the key:

***C.2.a. WHITE MATTER MATURATION* (ref 1.3.5)**	
For each hemisphere, mark level of maturation noted on both T1 and T2	
Stage	***C.2.a. Myelination***
W0	Brainstem, cerebellar peduncle, inf. Colliculus, cerebellar vermis
W1	Subthalamic nuclei, globus pallidus, ventrolat thalamus
W2	Part of PLIC (i.e., caudal portion), or very poor myelinatjon of PLIC
W3	Complete or near-complete PLIC
W4	Corona radiata
W5	Corticospinal tracts of the precentral and postcentral gyri
NE	Not Evaluable

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

c. **C.2.b WHITE MATTER Corpus Callosum**
   i. Should read "thinning" rather than "enlargement" for column headings "Mild-Moderate enlargement" and Marked enlargement". This has been changed on the key.

d. **C.2.e WHITE MATTER Qualitative assessment of lateral ventricular dilation**
   i. Currently, the form indicates that only one box may be checked per hemisphere – this needs to be changed specifically to allow **SHUNTED** to be checked along with another box for each hemisphere
      1. For instance, there may be a shunt in place in the left

4) **D.3.A - HEMORRHAGE GRADES (Papile classification)**
   a. We are not utilizing the section on Papile classifications (D.3.A)
      i. This is because these MRI's are LATER imaging, Papile classifications are not utilized on the late CUS form, and any intraventricular hemorrhage or echodensity would be identified on the "signal abnormalities" section (B) utilizing the VENT site code.

5) **Need for massive injury code...similar to "hemispheric devastation" assignment in Hypothermia?**
   a. There have been a few cases already in which there is massive (usually bilateral) ventricular dilation, and enormous injury leading to ***"obliteration of sulcation and gyration landmarks, deformation"***. I have been writing these in - using about those words - on the front of the envelope and also in the E. (COMMENTS) section on page 3 of the form. We also write what this severe injury likely represents – in most cases so far, massive bilateral post-hemorrhagic hydrocephalus, in some cases with porencephalic cyst.
   b. If Dr. Barnes judges this to be the case, ***he <u>cannot</u> assign gray matter maturation score (C.1.a), Subarachnoid space measurements or assessments (C.1.b) or myelination score (C.2.a) so those will be left blank. Also, there will be NO cavum septum pellucidum or Sylvian fissure measurements made (see below).*** However, Dr. Barnes is still able to detail signal abnormalities (if any are specifically seen)

6) **ADDITIONAL MEASUREMENTS:**
   a. We will always (except in the case above with "obliteration of landmarks) be measuring the following - **cavum septum pellucidum (CSP), Sylvian fissure Left (L) and Right (R).** (Sylvian fissure may be abbreviated also to SF)
      i. When I am reading with Dr. Barnes, I always record these measurements in E. Other, "COMMENTS" at the end of page 3. However, if Dr. Barnes reads alone, he may record them in blank spot at the end of page 2 (but he is trying to break this habit).

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

ii. Similar to the case with additions to the CUS central reading form after the first central reading (May 10-11), we would therefore like specific data fields to be created for these measurements. I have added the following to the KEY under section E. Other:
    1. Cavum septum pellucidum (CSP)
        a. "Cavum septum pellucidum: measure CSP size in millimeters on axial image. If no CSP is seen, record 0"
    2. Sylvian fissure
        a. "Record Left (L) and Right (R) Sylvian fissure size in millimeters on maximum AP dimension on axial imaging"

7) "Qualitative assessments"

a. This study will be the first to make such complete and detailed measurements. Previous studies have infrequently reported measurements associated with enlargement or thinning of specific brain features. For instance, there are extremely limited data on the actual expected measured thickness of the corpus callosum at term, much less that seen in preterm infants at term equivalent age.
b. For the purposes of our scoring sheet, qualitative assessments are meant to be just that – qualitative. We have some guidelines as seen in the key, but these qualitative assessments are not necessarily based on measurements, but rather are meant to reflect the clinical impression of an experienced neuroradiologists. This would be similar to a clinical reading.
    i. The "qualitative assessment" may be evaluated on any image or group of images. For instance, the corpus callosum "qualitative" assessment may be evaluated on axial and sagittal images; ventricular dilation may be evaluated on axial and coronal images; etc..

8) Expanded reference list:

a. The reference list has been expanded as follows for completeness, and included in the Key

1. Huppi P, et. al. Peds Res 1996;39:895-901
2. Inder T, et. al. J Pediatr 2003;143:171-179
3. Childs A-M, et. al. AJNR 2001;22:1577-1582
4. Valkama AM, et. al. Acta Paediatr 2000;89:348-355
5. Counsell S, et. al. AJNR 2002;23:872-881
6. Poland RL, Slovis TL, Shankaran S. Pediatr Radiol 1985;15:12-14
7. Miller SP,et. al. AJNR 2003; 24:1661-1669
8. McArdle CB, et. al. Radiology 1987; 162:223-229

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

9. Chi JG, et. al. Ann Neurol 1977; 1:86-93
10.Martin E, et. al. J Comp Assist Tomog 1988; 12:917-922
11. Woodward L, et. al. NEJM 2006; 355:685-699 and Suppl material

The following pertain to the SUPPLEMENTAL FORM:

1) EVALUTING WHITE MATTER LESIONS FOR SUMMARY CLASSIFICATIONS: White matter lesions will be "counted" for both summary classification systems if a signal abnormality is seen on any sequence and judged by Dr. Barnes to represent a true white matter lesion. In other words, not only the T1 and T2 weighted images will be evaluated for these scores.
2) B.1. Miller Classification
    a. Note that there are 2 typos in the line following "Moderate". See below in red is corrected – the less than and greater than signs got turned around in the forms

Moderate	3 or more areas of T1 signal abnormality or these areas measuring **>2 mm but <5% of** hemisphere involved

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

Non-Cystic abnormalities	T1 hyper or hypo T2 hyper FL hyper ***Note; T1 hyper in absence of marked T2 hypo is likely gliosis*
Hemorrhage or mineralization	GRE hypo +/- T1 hyper and MARKED T2 hypo

C. MATURATION AND DEVELOPMENT

C.1. GRAY MATTER MATURATION **(ref. 1-3, 8-10)**

Stage	***C.1.a. Cortical maturation markers***
G0	Frontal and occipital cortex completely smooth, insula widely open
G1	Frontal cortex still smooth, but some sulci in occipital cortex
G2	Frontal and occipital cortex with some convolutions, frontal sulci shallow. Internal surface of insula more convoluted.
G 2.5	All G2 markers, approaching G3 - however, secondary gyri are not present in all areas as noted in G3
G3	Presence of marginal sulcus and paracentral gyrus. Frontal and occipital cortex folded and richer in sulci. Insula more convoluted and infolded. Secondary gyri present in frontal, superior and middle temporal, pre- and post-rolandic, insula, occipital
G 3.5	All G3 markers, approaching G4 – secondary gyri of G4 present, but anterior and posterior orbital gyri may not be established
G4	Secondary gyri present transverse and inferior temporal; Anterior and posterior orbit gyri should be established.
G5	Teritiary inferior temporal and inferior occipital gyri and sulci present. White matter now isointense with gray matter on T1
NE	Not Evaluable

C.1.b. Subarachnoid Space For each hemisphere, mark as described

Record widest measure at ant./post. IHF, lat. post. parietal SAS at centrum semiovale. The following may serve as guidelines for severity of enlargement

Normal	<4 mm; or "small space, barely visible" (ref #11)
Mild-moderate enlargement	4-6 mm; or "mildly enlarged CSF space with visible enlarge of interhem and extracereb space" (ref #11)
Marked enlargement	>6 mm; or "more substantially enlarged, visible space between gyri and interhem and extracereb" (ref #11)

Stage	***C.2.a. Myelination***
W0	Brainstem, cerebellar peduncle, inf. colliculus, cerebellar vermis
W1	Subthalamic nuclei, globus pallidus, ventrolat thalamus
W2	Part of PLIC (i.e., caudal portion), or very poor myelination of PLIC
W3	Complete or near-complete PLIC
W4	Corona radiata
W5	Corticospinal tracts of the precentral and postcentral gyri
NE	Not Evaluable

C.2.b and c Corpus Callosum Thinning Qualitative Summary Question

NOTE: These are *qualitative assessments*; quantitative measures will be primary

C.2.d. Lateral ventricle measurements

Measure diameter ventricular and brain region as indicated in millimeters for both left and right. ***NOTE:*** V/B ratio can be calculated from these measures by data center after submission of completed form

C.2.e. Qualitative assessment of lateral ventricle dilation (ref 4,6,7)

Guidelines from the literature include the following:

"Mild": abnormal, with V/B ratio ~1/3; "moderate": V/B ratio 1/3-2/3; "severe": V/B ratio>2/3 (measured at level of atria on coronal)

Mild ventriculomegaly": largest ventricular diameter at level of glomus of the choroid = 8-10 mm; "Moderate-severe": >10 mm (ref. 7)

Frontal horn, midbody	V/B ratio>0.35* = "abnormal"
Trigone	V/B ratio >0.60 = "abnormal

C.2.f. Third, Fourth Ventricle, temporal and occipital horn

Measure indicated region in mm. Then assess qualitatively as described

E. OTHER: Report structural abnormalities and describe in comments

The following measurements will also be recorded in COMMENTS area:

Sylvian fissures: Record L and R Sylvian fissure size in millimeters on maximum AP dimension on axial imaging

Cavum Septum Pellucidum (CSP): Record CSP in millimeters on axial imaging. If no CSP is seen, record 0.

Subject: SUPPORT Protocol and forms

As you may recall, Ed Bell had requested to share the SUPPORT protocol and forms with Ophthalmology colleagues to develop a secondary analysis of the SUPPORT trial data to look at growth and development of ROP. I have discussed with Drs. Finer and Duara who are ok with this provided the primary analyses and the secondary growth analyses are first done. **Send me a yes/no vote to share the forms with Ed's colleagues by September 15.**

Thanks
Rose

>>> "Higgins, Rosemary (NIH/NICHD) [E]" <higginsr@mail.nih.gov> 9/11/09 6:39 AM >>>
As you may recall, Ed Bell had requested to share the SUPPORT protocol and forms with Ophthalmology colleagues to develop a secondary analysis of the SUPPORT trial data to look at growth and development of ROP. I have discussed with Drs. Finer and Duara who are ok with this provided the primary analyses and the secondary growth analyses are first done. Send me a yes/no vote to share the forms with Ed's colleagues by September 15.

Thanks
Rose

Subject: RE: SUPPORT Protocol and forms
Date: Friday, September 11, 2009 10:02:50 AM

Yes, with a great deal of concern for the process
And compromise of the main trial and pre planned secondaries.
New secondaries, particularly that growth rates could substitute for known
Risk factors for ROP which is speculative at best, should only occur after
The preplanned secondary studies.

Subject: RE: Duke
Date: Wednesday, September 09, 2009 12:22:44 PM

Rose:

Please see below for small suggested changes. I also got the sense from Kris that Duke may be doing a lot of other industry funded studies, with the result that NRN studies are getting lower priority/attention. However, that may be something you enquire about when you are there, rather than putting it in this email. Incidentally, late September is not good for me (Study Section, among other things), but you may not need me there, and I could see if Dennis can make it.

As you may know, Kris is (b) (6) and you may not hear back from her right away.

Thanks

Abhik

Importance: High

Carolyn, Kris and Abhik – I want to send this to Ron today: please edit!!!

The staff at RTI have briefly updated me on last week's visit to Duke. There are several issues which need to be addressed in person. I can come to Duke on 9/29 – will that work for you and the site? It is imperative that I visit in the next few weeks.

The following outstanding items are of urgent importance:

1. SUPPORT primary outcome data including death, BPD and ROP for each of the 64 infants enrolled at Duke needs to be formally approved by you or Mike Cotten (as alternate PI). This is time sensitive and needs to be done by the end of the month as the investigators are anxious to have a final data set.
2. Primary source data need to be available in the patient's chart. Apparently, ophthalmology exams from the primary source, or copies thereof, are not readily available, which makes it impossible to properly audit these data. ~~There is difficulty in obtaining eye exams from the primary source.~~
3. IRB approval process has several levels of review. We would like an efficient system for NRN studies.
4. Collaborative organization of the team at the Duke site that would enable more efficient running of NRN studies.

Subject: Hot Topics 2010

Hi,
Jerry Lucey would like a presentation from the SUPPORT study in 2010 at Hot Topics - NOT THIS YEAR, BUT NEXT YEAR.

The current plan is to have the first two papers written and submitted in the near future, probable abstracts at PAS and presentation at American Thoracic Society 2010 (May) if accepted.

Neil and Wally are ok with this.

Please send me a yes/no vote for presentation by September 11.

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

Thanks
Rose

From: Wally Carlo, M.D.
To: Finer, Neil; Das, Abhik; Higgins, Rosemary (NIH/NICHD) [E]
Subject: RE: SUPPORT data!
Date: Tuesday, September 08, 2009 6:51:13 PM

There is an absolute risk diff (NS)for phys def BPD of 3% favoring the low sat group but there are several biases including that the physiologic test not used if FiO2 is >30% (so less babies in the higher sat group would have an attempt to be weaned off with the phys def test) and that clinicians may be more likely to go back on O2 during the testing if baseline FiO2 is higher before the testing. Thus, this ARR is likely an over-estimation of the truth. With such a large sample size, I think the best interpretation is that there is not a large benefit of low sats targeting for the reduction of BPD.

What do you think of these thoughts?

Wally

Dear Rose,
I wondered if the significant effect on BPD outcome is a matter of higher oxygen sat group "needing" oxygen to reach that target sat-or something else? The physiologic BPD was no different between groups.--Carol

Hello Everyone
I am delighted to send you the first look at the SUPPORT Results with thanks to Marie and Abhik.
Please find the basic demographic tables and the outcome of BPD and death etc. You will note that Death/BPD using the need for oxygen at 36 weeks as the postulated primary – because that was the data we based the study on – is significant both unadjusted and adjusted. Note that BPD is also less for the Low SpO2 group – but for that study, we need ROP which we are still waiting for.
Congratulations on a study well done to you all and the coordinators, and RTI
Wally Wade and I will be at RTI a week today to review all the data and I have already started the first paper.
Be well
Neil

Neil,
What do you think? I would hate to have the data picked clean before we even get a chance to look at it. Boundaries are hard to establish once a sub-analysis gets underway.
Shahnaz

Ed would like to submit a proposal – should I ask him to send it?
Thanks
Rose

Does that mean we can't submit the new proposal until the main trial is in press?

Rose,
Sorry – just back from India. I understood from most of the discussion around this that there was concern about data use before we publish our main findings. I would prefer to wait until we publish our main findings before we share findings outside the study.
Again, sorry for the delay.
Shahnaz

Shahnaz; Navarrete, Cristina
Subject: Request for collaborative proposal

Based on a recent publication Löfqvist et al from Lund (Arch Ophthalmol 2009; 127:622), Ed Bell is interested in collaborating with Drs. Binebaum and Quinn from CHOP Ophthalmology to evaluate growth rates and evolution/resolution of ROP. Please send a yes/no vote by August 17 to share the SUPPORT main trial protocol/forms as well as the growth secondary protocol/forms with the folks from CHOP.

Subject: Cross-form queries for SUPPORT infants

Attached is a zip file containing documents with cross-form queries (GDB and SUPPORT forms) for SUPPORT infants. A summary of the queries is also attached. These queries impact some of the secondary outcomes for the SUPPORT papers, so hopefully the centers will be able to clear them up quickly. As before, if they can make a note of how the query was resolved and return the query document to us with those notes it will help us track their progress. I will be out of town for the next two weeks, but hopefully the centers will be able to resolve most of the queries by the time I return on September 21.

Thanks,
Marie

Secondary cross-form queries (may be >1 per infant)

The FREQ Procedure

Query			
queryNum	Frequency	Cumulative Frequency
Birth date was >120 days ago but SUPP09 has not been completed	8	8
Infant was outborn per NG02 but was enrolled in SUPP01	2	10
NG02 birth time does not match SUPP03 delivery time	55	65
NG02 birth date/time is after SUPP04 NICU admission time	3	68
Per SUPP03 status following resuscitation was death but per SUPP04 infant was admitted to NICU	1	69
NG03e death date/time is before NG02 birth date/time	1	70
NG03 status is discharge but status date (Q A.2.) is different from discharge date (Q N.1.)	17	87
NG03 status is death but status date (Q A.2.) is different from death date (Q O.1.)	2	89
Date of death on NG03e differs from date of death on SUPP08	6	95
Date of death on NG03 differs from date of death on SUPP08	2	97
NG05 status is discharge but status date (Q A.2.) is different from discharge date (Q D.1.)	2	99
Infant status on NG03 and SUPP09 are the same but dates are different	24	123
NG03 surfactant date/time is before NG02 birth date/time and/or SUPP03 delivery date/time	12	135
SUPP03 surfactant date/time is before NG02 birth date/time	2	137
SUPP04 surfactant date/time is before NG02 birth date/time	1	138
SUPP03 surfactant date/time does not match NG03 surfactant date/time	19	157
SUPP04 surfactant date/time does not match NG03 surfactant date/time	17	174
Infant intubated in DR per NG03 but was not intubated in DR per SUPP03	14	188
Infant intubated for the 1st time in NICU per SUPP04 but was intubated in DR per SUPP03	1	189
Per SUPP04 indication for NICU intubation was surfactant but surfactant was not given	1	190
DR chest compressions is inconsistent on SUPP03 vs NG03	3	193
Per SUPP03/NG03 infant received chest compressions or epinephrine in the DR but AE was not reported on SUPP08	37	230
Per SUPP08 infant received chest compressions or epinephrine in the DR but neither was reported on SUPP03	1	231
Per SUPP08 infant received chest compressions or epinephrine in the DR but neither was reported on NG03	7	238
Per SUPP08 infant had pneumothorax but it is not recorded on NG03	4	242
Per SUPP08 infant had pulmonary hemorrhage but it is not recorded on NG03	8	250
Per SUPP09 infant had a HUS at 4-21 days but cranial sonogram is not recorded on NG03	3	253
Per SUPP08 infant had IVH grade 3-4 in 1st 14 days but severe IVH is not recorded on NG03	4	257
Per SUPP08 infant had IVH grade 3-4 on DOL 4-14 but severe IVH is not recorded on SUPP09	2	259
Per NG03 infant had HUS with IVH 3-4 on DOL 4-21 but severe IVH is not recorded on SUPP09	18	277
Per SUPP09 infant had HUS with IVH 3-4 on DOL 4-21 but severe IVH is not recorded on NG03	7	284
Per MRI01 infant had HUS with IVH 3-4 on DOL 1-28 but severe IVH is not recorded on NG03	10	294
Per MRI01 infant had HUS with IVH 3-4 on DOL 4-21 but severe IVH is not recorded on SUPP09	11	305
Per NG03 infant had HUS with PVL on DOL 4-21 but PVL is not recorded on SUPP08	5	310
Per SUPP08 infant had NEC requiring surgery, but per NG03 infant had medical NEC only	1	311
SUPP08 AE entered for DOL >14	12	323

Hi,
Yes, DRH is under a separate IRB. We do have all dates of the entire IRB submission process for all the most current studies.

Will keep you posted - no worries - we will have fun when you get back going through this....
Thanks,
Kris

Subject: Re: Duke

Is Durham Regional covered under the Duke IRB or is it a separate institution - probably separate based on your comments below.
Also, do we have a list of dates for their IRB process for the most recent 3-4 protocols?
Thanks for doing this - sorry I'm not there.

Subject: RE: Duke

Primarily missing ROP source ophthal reports (only 2 of the 15 cases had all reports; most didn't have 50%) however, I believe we may be able to rectify this as Kim has asked the eye center to retrieve these. There is one case however that did not report the left eye as having surgery (and they did).

Other problems;

consent issues with the MRI secondary; in the most recent version of the main Support consent, the MRI secondary was rolled into it with an opt in/opt out check box and neither box was check for one or more infants

There is confusion over Durham Regional being a secondary to Duke; apparently they are no longer and have no IRB approvals for nay NRN study

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

There have been at lease 6 cases (regarding Marie's recent BPD queries) where Duke has reported status as D/C to home but in reality they were transferred to Durham Regional (which should be status if they are no longer a satellite site). In short; these kids were transferred prior to the 36 wk date and D/C'd home form DRH; they have the wrong status and wrong date of status and are using an F5 comment to let us know they were transferred.

There was one kid withdrawn from study that we did not know about; they competed a PD stating the withdrawal but did not let you or RTI know. This kid's study oximeter was essentially unblinded close to the 36 week date and the PI (Mike C.) found out, decided the kid could no longer be in study). When I talked to Abhik about it he did not this the kid should not have been taken off study; a PD would have sufficed; we do though, have data on this kid - more on that to come.

There was one kid that did not give consent for GDB but did for Support so they held all data (did not transmit support data) until they were to return for FU so they could ask again for GDB consent; this mean we actually have one more kid enrolled to Support we do not currently have counted.

There are minor inconsistencies with data

We have not looked at FU yet; Jamie will be with us tomorrow; more to come then.

This is just a brief, from memory low down; we have everything written down in the monitoring room and Carolyn with have that up in Rockville next Tuesday.

Thanks, and I hope you and all your family are taking care; hope all is relatively well.

Kris

Subject: RE: Oxygen Saturation Targeting Paper

Hi Wally, Rose, Abhik, Marie and Wade
I think one approach would be to write the Methods to be fully descriptive of the study.
In the Introduction, the last paragraph should indicate that we did the study to determine the most appropriate SpO2 level for the treatment of the very preterm infant. The DSMC blinded interim analyses for this trial were made available to the investigators after the trial was complete and the last infant reached 55 weeks of age. They had noted a trend to increased mortality in one of the SpO2 groups which did not reach the predetermined boundary for stopping the trial. The Principal investigators and data center then undertook a safety analyses to evaluate any potential adverse outcomes while waiting for the final ROP diagnosis for all enrolled infants. This analysis did not unblind the investigators to any ROP outcomes by treatment group but evaluated all other available outcomes for which final patient data was available for the randomized infants. We now report the results of these analyses

This will avoid the need to report any ROP outcomes and I suspect that we should report these when we do the follow-up paper.
Let me know what you think
Neil

Subject: Oxygen Saturation Targeting Paper

Dear Marie, Neil, Rose, Abhik, Wade:

I have drafted the tables as requested by Marie. I have also drafted the CONSORT figure so it is easy to identify the gaps. Marie also has the request that we addressed yesterday.

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

I am enclosing the 2nd draft of the paper. As agreed, I have changed the focus away from retinopathy. I am still struggling on how to present the primary outcome measure and hypothesis and yet not present the retinopathy methods at the present time or the results in the table. I think we may have to leave the retinopathy in the Methods because that was assessed by the DMC and when we get to the results, we can clarify that we will not be reporting our retinopathy.

I am enclosing the draft 2.0 of the paper with the tables as drafted to make it easier to add additional results.

I am still working to improve the Introduction and Methods. I will write the Results and Discussion next week after I get the data analyzed by Marie.

Thanks
Wally

Running head: oxygen saturation and retinopathy of prematurity

Key words: prematurity, extremely low birth weight infant, neonatal mortality, oxygen toxicity

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

ABSTRACT

Background

Non randomized studies suggest that the incidence of retinopathy decreases in premature infants with exposure to lower levels of oxygenation than previously maintained but the range of oxygen saturations that reduces retinopathy without increasing adverse outcomes is not known.

Methods

1310 infants of 24 to 27 weeks gestation born at 20 centers of the Neonatal Research Network were randomly assigned at birth to oxygen saturation targets of 85 to 89% or 91 to 95%. The primary outcome was a composite of threshold retinopathy of prematurity, eye surgery for retinopathy, and/or death.

Results

Conclusions

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

INTRODUCTION

Retinopathy of prematurity remains an important cause of blindness and other visual disabilities among prematurely born infants. The incidence of retinopathy of prematurity is increased with exposure to high levels of oxygenation in premature infants. Oxygen saturation levels previously thought to be in the upper limits of normal appear to increase the risk of retinopathy of prematurity.[1,2,3] Oxygen toxicity may also increase the risk of mortality[4,5], bronchopulmonary dysplasia[6,7] and other morbidities. While data from prospective observational and retrospective studies suggest that maintenance of oxygenation at ranges lower than what have been used may decrease the incidence of retinopathy of prematurity, there is no conclusive evidence regarding the oxygenation levels that reduce retinopathy of prematurity without an increase in adverse effects.

We conducted a 2 x 2 factorial-design multicenter randomized trial of oxygen saturation targeting, testing the effect of a lower oxygen saturation range (85-89%) as compared to a higher oxygen saturation range (91-95%) on the incidence of threshold retinopathy of prematurity, eye surgery for retinopathy, and/or death among infants of 24 to 27 weeks gestational age at birth. The factorial design allowed comparing prophylactic/early surfactant versus continuous positive airway pressure, thus, controlling for the approach to ventilatory support.

METHODS

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

The institutional review boards at all Neonatal Research Network clinical centers and at Research Triangle International (data center) approved the trial. Written informed consent was obtained from the parent or guardian of each participant before delivery.

Patients

Infants of $24^{0/7}$ to $27^{6/7}$ weeks without a decision to forgo support were eligible for enrollment at birth. Exclusion criteria were outborn infants and major congenital anomalies. Multiples were randomized to the same arm of the trial.

Enrollment and treatment

Infants were stratified by gestational age ($24^{0/7}$ to $25^{6/7}$ weeks or $26^{0/7}$ to $27^{6/7}$ weeks) and by center. Infants were randomly assigned by means of double-sealed envelopes to oxygen saturation targeting of 85 to 89% or 91 to 95% with masking using electronically-altered pulse oximeters with output display of 88 to 92% for these oxygen ranges, an offset of 3% as previously used to separate oxygen saturations in premature infants.[8] They were also randomly assigned to respiratory support using either prophylactic/early surfactant with conventional ventilation management or to continuous positive airway pressure with a permissive ventilatory strategy. The oxygen saturation values displayed reverted to actual values when less than 85% or greater than 95%. Saturation targeting was initiated within the first two hours after birth. Oxygen saturation targeting with the altered pulse oximetry was continued until 36 weeks post-menstrual age until the infant remained on room air and off the ventilator/ continuous positive airway pressure for more than 72 hours. Infants weaned to room air but who subsequently received oxygen before 36 weeks were placed back on the assigned study pulse oximetry. Adjustments

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

in supplemental oxygen to target oxygen saturations were performed by the clinicians, not by the research staff.

Assessments

Data were collected until discharge, were 36 weeks post-menstrual age, or 120 days postnatal age, whichever occurred last. Research nurses recorded all data using standardized definitions. Threshold retinopathy of prematurity (New Type 1 threshold per Early Treatment of Retinopathy [ETROP] Cooperative Group[9]) was coded if any of the following four findings were present up to 55 weeks post-menstrual age:

If in zone 1:	Stage 3 retinopathy of prematurity, even without plus disease
	Plus disease with any stage retinopathy of prematurity
If in zone II:	Plus disease with stage 2 retinopathy of prematurity
	Plus disease with stage 3 retinopathy of prematurity

Surgical intervention included laser therapy, cryotherapy, laser/cryotherapy, scleral buckle, and vitrectomy. Death was coded up to 36 weeks post-menstrual age for the primary outcome measure. Outcomes included predefined clinical diagnoses and potential adverse events.

Statistical analysis

The primary analysis of this factorial trial was a logistic regression analysis of the percentages of infants in each group (lower versus higher oxygen saturations) who developed the primary outcome. An absolute difference of 10% between the two treatment groups was considered clinically important. To detect this difference, we planned to enroll 1312 infants for 80% power and a baseline estimated rate of 45% of death/threshold retinopathy/surgery and based on an increase by a factor of 1.12 to account for

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

randomizing multiples to the same treatment group and a increase by a factor of 1.17 to account for the expected attrition after discharge and before follow up. The trial was not powered to determine an interaction between the two interventions. Intention-to-treat analyses were performed. The denominator used to calculate the rate of each outcome was the number of infants for whom that outcome was known. Analyses were conducted by the staff at the data center. A two-sided P value of less than 0.05 was considered to statistically significant. Analyses did not include adjustment for multiple comparisons. An independent data safety monitoring committee reviewed the primary outcomes, adverse events and other interim results at ~25%, 50%, and 75% of planned enrollment. Pocock boundaries were used to develop stopping rules for interim safety monitoring.

RESULTS

DISCUSSION

Tables Aug 29.docx

Hi Guys
Thanks for yesterday – a tumultuous day to say the least. Marie – you are great and thanks for being so patient and doing the analyses – over and over and over!!!
Well, Wally will no doubt be surprised at the outcome but here it is
I decided that the gender difference is too large to ignore p=.054 and asked that we adjust for it
We did and no more significance for Death/BPD
That's the truth and so be it!!
It looks like both papers will be about death, decreased by 8% for our small strata or NNT of 12.5 for infants of 24-25 wks as good as I have ever seen. All directions of BPD are better as is time on vent, need for PNS etc and there are no increased adverse outcomes
So I have rewritten the manuscript for all of your reviews
Marie please check the actual p values and correct them - I estimated from what I remembered
Please also correct the tables where needed if at all.
The paper is about 400 words too long so everyone can slash and burn
Wally we will go together to the NEJM. The 2 papers provide a balance and the negative message for SpO2 is offset by the positive in CPAP –
Who knows what the journal will accept – but we are completely in keeping with our protocol, manual and web info
Let's try to get these to the journal within 4 weeks - that would deal with the need to provide the other trials with needed data – we can also do that sooner if we want -I propose a Subcommittee meeting in 2 weeks when they can all see both manuscripts
I would keep still about everything till then – Marie and Abhik can check the data and stats so we have it right.
I don't feel a need to rush with our data anymore – I think having it peer reviewed would be good and our DSMC should also have a chance to see the outcomes and provide feedback and counsel about discussing our outcomes with the other trials
Big breath in !!!!!
Neil

Abstract

Background: The most appropriate initial and ongoing respiratory support for the extremely low birthweight infant (ELBW) has not been established by adequate prospective evidence. The current usual approaches include the early use of continuous positive airway pressure (CPAP) or the early administration of surfactant following endotracheal intubation.

Methods: The SUPPORT study was a randomized multicenter factorial trial that enrolled consented preterm infants of 24 0/7ths weeks to 27 6/7ths weeks by best obstetrical estimate within 2 prospective strata, 24 to 25 6/7ths weeks, and 26 to 27 6/7th weeks. Infants randomized to CPAP were treated with CPAP initiated in the delivery room and were subsequently treated using a permissive strategy allowing higher PaCO2s and extubation at higher ventilator settings. Infants randomized to surfactant were intubated and received surfactant within 60 min minutes of birth. All infants were also randomized to one of 2 ranges of SpO2 while in the NICU and receiving supplemental oxygen, a low target range of 85% to 89% and a high target range of 91% to 95% using specifically altered blinded oximeters.

Results: The study enrolled 1316 infants from February 2005 to February 2009. There were 565 infants enrolled in the lower gestational age strata, and 751 in the higher strata. In the delivery room, 66% of the CPAP infants received positive pressure ventilation compared with 93% of the surfactant infants, and surfactant was given to 14% of the CPAP versus 51% of the surfactant group, and 67% of the CPAP infants received surfactant at any time during their hospitalization, (all $p<0.001$). There were no differences overall for death in the delivery room nor any differences in length of stay, or days of oxygen for survivors, and the need for oxygen at discharge. More CPAP infants were alive and off mechanical ventilation by day 7, ($p=0.015$). All infants in the Surfactant arm were intubated, compared with only 77% of the CPAP infants required intubation during their nursery course, ($p<0.001$). There were no differences between the groups for airleaks including penumothoraces. The primary outcome of death or BPD, defined as the need for supplemental oxygen at 36 weeks post conceptional age was 48% versus 54%, (unadjusted $p = 0.035$, $p= 0.042$ when adjusted for gestational age, center and familial clustering and gender). There was a significantly lower mortality in the 24 to 25 weeks strata for the infants in the Surfactant arm, (24% vs 32%, unadjusted $p=0.026$, adjusted $p=.04$).

Conclusions: The use of early CPAP with a permissive ventilator strategy results in a decrease in death or survival with BPD defined as the need for oxygen at 36 weeks post conceptional age compared with the use of surfactant within 1 hour of birth and a conventional mechanical ventilation approach. There were no increased adverse outcomes in the CPAP group, and the surviving infants will be followed for a complete neurodevelopmental assessment at 18 to 22

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

months. Early CPAP and the use of a permissive ventilator strategy is an evidence based approach for the initial respiratory support of the ELBW infant.

Introduction:

At the present time, there is no agreement as to the optimal approach for the extremely low birth weight (ELBW) infant following delivery. Positive End Expiratory Pressure (PEEP) has been shown to be of benefit in maintaining functional residual capacity (FRC) and continuous positive airway pressure appears beneficial during cardiopulmonary resuscitation[1]. Gregory et al in 1971 first demonstrated that the use of CPAP started at approximately 5.9hours (+12.4hrs) for their infants < 1500 gm at birth, improved oxygenation[2] in newborn infants with respiratory distress; these observations were followed by prospective studies that demonstrated improved survival in premature infants treated with early CPAP[3]. A review of prospective studies evaluating early (not delivery room) CPAP in the pre-surfactant, pre-antenatal steroid era found that early CPAP improved survival overall and for infants greater than 1500 gm, and was associated with increased pneumothoraces.[4] A more recent review of prophylactic CPAP started in the delivery room reviewed only 2 available trials and found no significant difference between the CPAP and conventionally managed infants and noted a trend to increased adverse outcomes for the CPAP treated infants.[5]

There is substantial retrospective evidence suggesting a benefit for early CPAP in experiences from both the US and other countries.[67] These reports have documented a decrease in the need for mechanical ventilation among very preterm infants without an increase in morbidity following the initiation of early CPAP treatment.[8910]

The current available evidence demonstrates that prophylactic and early surfactant treatment at less than 2 hours of life significantly decreases mortality, air leak, and BPD in preterm infants.[1112] Overall surfactant has not been reported to significantly reduce BPD, but may do so for the most immature infants and has not been found to significantly reduce subsequent neurodevelopmental impairment (NDI). [13]

The recent COIN trial randomized 610 infants from 25 weeks 0 days to 28 weeks 6 days gestational age at birth, who were able to breathe at 5 minutes of age, and had evidence of respiratory distress at that time. Infants were randomized to either intubation and ventilation

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

or CPAP received 8 cm H20. CPAP infants were intubated if they met failure criteria.[14] This study did not compare early CPAP to the early administration of surfactant, and surfactant use followed unit standard of care. There was a significant primary increase in the occurrence of pneumothoraces in the CPAP group, most occurring within the first 2 days (9.1% vs 3.0%, p=.001), consistent with the findings of an earlier meta analyses4 and a reduction in death or the need for oxygen at 28 days in the CPAP infants (odds ratio, 0.63; 95% CI, 0.46 to 0.88; P=0.006) with no difference in death or BPD at 36 weeks.

In view of the current interest in the use of early CPAP and the lack of prospective comparisons of this approach with the evidence based intervention of prophylactic or early surfactant, the SUPPORT study was designed to compare these approaches for the most preterm infants. We also randomized infants to 2 ranges of pulse oximetry targets during their exposure to oxygen using a factorial design, and the results for the oximetry study will be reported separately.

Methods

This was a prospective, randomized, factorial 2X2 design multi-center trial conducted by the NICHD Neonatal Research Network. This report describes the prospective comparison of CPAP and a permissive ventilatory strategy begun in the delivery room and continuing in the NICU with the early (< 1 hour) intratracheal administration of surfactant followed by conventional mechanical ventilation.

Infants were also randomized to a prospective comparison of a lower SpO2 range (85% to 89%) with a higher more conventional SpO2 range (91% to 95%) until the infant was no longer requiring ventilatory support or oxygen using purpose altered oximeters. These results will be separately reported.

The primary hypothesis of this study was that relative to infants managed with prophylactic/early surfactant and conventional ventilation that the use of early CPAP and a permissive ventilatory strategy in infants of less than 28 weeks gestation with continuing CPAP in the NICU will result in an increased survival without BPD at 36 weeks.

Eligible infants were 24 0/7ths to 27 6/7th weeks at birth by best obstetrical estimate, born at a randomizing center, for which a decision has been made to provide full resuscitation without known malformations, and for whom parental consent had been obtained. The infants were randomized to 2 gestational age strata, 24 0/7ths to 25 6/7ths weeks, and 26 0/7ths-27 6/7ths weeks.

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

CPAP Arm - Delivery room management: A T-piece resuscitator, a neonatal ventilator, or an equivalent CPAP methodology was used at all sites for the delivery room administration of CPAP. CPAP or ventilation with PEEP both at a recommended 5 cm H_2O was utilized if the infant required positive pressure during resuscitation. CPAP was continued until admission to the NICU using the Neopuff or equivalent device and a face mask or nasal prongs. CPAP infants were not to be intubated for surfactant only in the DR, and CPAP infants who required intubation for resuscitation were to receive surfactant within 60 minutes of birth. Intubation for these infants was performed only for the standard NRP indications including failure to respond to positive pressure ventilation (PPV) with evidence of continuing cyanosis or bradycardia, the need for chest compressions, the need to administer intratracheal medications, or other situations in which the resuscitation team determined that surfactant is urgently required.

NICU management: Intubation was performed at any time for the occurrence of repetitive apnea requiring bag and mask ventilation, clinical shock, sepsis, and/or the need for surgery . While intubation was never required by protocol, CPAP infants could be intubated if they met any of the following criteria: an FiO_2 >.50 required to maintain an indicated SpO2 $\geq$ 88% for one hour, an arterial $PaCO_2$ > 65 torr documented on a single blood gas, or hemodynamic instability defined as a low blood pressure for gestational age and/or poor perfusion, requiring volume and/or pressor support for a period of 4 hours or more. If intubated within the first 48 hours of life infants were to receive surfactant.

Extubation for CPAP infants was to be attempted within 24 hours if all of the following criteria were met: a PaCO2 < 65 torr with a pH > 7.20, an SpO2 > 88% with an FiO2 < 50% , a mean airway pressure (MAP) < 10 cm H2O, ventilator rate < 15 bpm, an amplitude < 2X MAP if on high frequency ventilation (HFV), and hemodynamically stable, and without a clinically significant patent ductus arteriosus. Re-intubation criteria were the same as those for Intubation for the CPAP infants. After 3 intubations CPAP infants were treated using NICU standard of care.

Surfactant Arm: All infants were to be intubated within 1 hour of life and receive surfactant, followed by continued ventilation. All infants were to be extubated within 24 hours of meeting all of the following criteria: $PaCO_2$ < 50 torr and pH > 7.30 An FiO2 $\leq$ 35 with a SpO2 > 88%, a mean airway pressure (MAP) < 8 cm H_2O, ventilator rate $\leq$ 15 bpm, an amplitude < 2X MAP if on high frequency ventilation (HFV), and be hemodynamically stable with no evidence of clinically significant PDA. Once extubated Surfactant infants were treated using NICU standard of care.

These criteria were in effect for the first 14 days of life, following which the infant was treated as per NICU standard of care. For both arms of the trial intubation could be performed at any

time for the occurrence of repetitive apnea requiring bag and mask ventilation, clinical shock, sepsis, and/or the need for surgery.

Randomization was stratified by gestational age group, utilizing specially prepared double-sealed envelopes. Deliveries were randomized as a unit, and thus multiples, were randomized to the same arm of the trial.

Hypothesis and sample size: We hypothesized that early CPAP would reduce the incidence of death or survival with BPD at 36 weeks, (using the NRN occurrence of death or survival with BPD of 67% using the year 2000 data), and the occurrence of death or survival with neurodevelopmental impairment (NDI) at 18 to 22 months (using the NRN occurrence of NDI of 61% using year 2000 data) by 10%. We increased the sample size by a factor of 1.12 to allow for multiples to be randomized to the same treatment as this introduced a clustering effect into the design, and increased the sample sizes by 17% to adjust for attrition after discharge and before follow-up. This resulted in a sample size of 1312 infants. This sample size was not large enough to determine an interaction effects between the 2 factorial arms.

In addition there was a prospective decision to also evaluate the occurrence of BPD using the Physiologic Definition which required an attempt at oxygen withdrawal for infants who required < 30% oxygen at 36 weeks and assigned a diagnosis of BPD to any infant who required more than 30% oxygen at 36 weeks or who required positive pressure support. [15,16]

Statistical analyses: Intention-to-treat analyses were performed. The denominator used to calculate the rate of each outcome was the number of infants for whom that outcome was known. The primary analyses was a logistic regression analysis of the percent of each Group who developed their respective outcome measure of survival without BPD at 36 weeks and on the percent infants who survive without neurodevelopmental sequelae at 2 years. Adjustment was performed as pre-specified for gestational age, center and familial clustering. A two-sided P value of less than 0.05 was considered to statistically significant. An independent data safety monitoring committee reviewed the interim results, including those concerning adverse outcomes, four times. Pocock boundaries were used to develop stopping rules for interim safety monitoring.

The study was approved by Human Subjects Committees at all participating sites and RTI, the data center, and parental consent was required before delivery.

Results:

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

There were 1361 infants enrolled in this trial from Jan 1 2004 through to Mar 1 2009. The trial was temporarily suspended by the DSMB because of concerns regarding the oximetry data in November 2005 but after a complete review the trial was continued in February 2006 with no protocol changes. The patient descriptive information for the CPAP versus Early Surfactant arms is shown in Table 1.There were 565 infants enrolled in the lower gestational age strata, and 751 in the higher strata. There were no significant differences for sex, birth weight Apgar scores or race between the 2 groups, although there were more boys in the CPAP arm, p=.056. The Surfactant group received significantly more epinephrine in the delivery room and had a higher DR mortality which was not significant.

In the delivery room, 66% of the CPAP infants received positive pressure ventilation compared with 93% of the surfactant infants, and surfactant was given to 14% of the CPAP versus 51% of the surfactant group, and 67% of the CPAP infants received surfactant at any time during their hospitalization, (all $p<0.0001$). Intubation in the DR occurred in 34% of CPAP infants compared with 93% of surfactant infants, $p<0.0001$, Table 2.

The primary outcome of death or BPD, defined as the need for supplemental oxygen at 36 weeks post conceptional age was significantly lower for the CPAP group compared with the Surfactant group, 48% versus 54%, ($p = 0.0354$, $p= 0.0424$ when adjusted for gestational age, center and familial clustering). There was a non-significant reduction in the occurrence of BPD using the need for supplemental oxygen, 40% vs 44%, p=.121 unadjusted, and p=.214 adjusted. Using the Physiologic Definition for BPD there was a non-significant decrease in the occurrence of BPD in the CPAP group (39% vs 41%, p=.63), and a non-significant reduction in the occurrence of death or Physiologic BPD at 36 weeks in the CPAP group, (48% vs 51%, p=.248). In view of the greater proportion of males in the Surfactant arm, we elected to do a further adjustment for gender, which reduced the significance of the primary outcome for death and BPD using oxygen alone to p=.07 and further increased in the p value for the primary using the Physiologic definition of BPD.

There were no differences overall for death in the delivery room nor any differences in length of stay, or days of oxygen for survivors, and the need for oxygen at discharge. (Table 3). More CPAP infants were alive and off mechanical ventilation by day 7, ($p=0.0149$). We prospectively recorded air leaks in the first 14 days and there were no differences between the groups, and no differences for medical or surgical NEC, PDA requiring surgery, severe IVH or airleaks during the hospital stay. All infants in the Surfactant arm were intubated, compared with 83% of the CPAP infants who required intubation during their nursery course, ($p<0.0001$). There was a significant reduction in the use of postnatal steroids for BPD in the CPAP infants compared with the Surfactant infants, 7% vs13%, $p=0.0004$). Death during the hospitalization was 4% lower for

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

the CPAP group overall, and was significantly lower in the CPAP arm the 24 to 25 week strata even after adjustment which included gender.

Strata Results: 24 – 25 weeks Gestation

There were significantly more non-Hispanic black infants in the CPAP group compared with the Surfactant group **(Marie – I think we adjusted for this please indicate this - please correct all my estimated p values for the adjusted outcomes – Thanks)** The differences are shown in Table 4 (24-25 wk Strata). CPAP infants had a significantly lower mortality (24% vs 32%, p=0.0264, p=.04 after adjustment for gestational age, center, familial clustering and gender. There was a significantly higher exposure to postnatal steroids for BPD, 21% vs 13%, p=0.0198) for the Surfactant group, and there were more infants alive and off mechanical ventilation at 1 week in the CPAP infants in this strata.

26-27 weeks Gestation

There was no difference in mortality for the CPAP vs Surfactant groups, 10% vs 11%. The CPAP infants required fewer days of oxygen, 36.8 vs 46.5, p=0.0097, lesser days of mechanical ventilation, 10.7 vs 14.2, p=0.0068, and less postnatal steroids for BPD, 3% vs 8%, p=0.0027.

Discussion:

The SUPPORT trial is the first large multicenter study to prospectively compare early CPAP, with early surfactant given within an hour of life to a large group of ELBW infants. The current trial is the largest study reported to prospectively compare the use of early CPAP and early surfactant for the ELBW infant and the only study to include infants of 24 weeks gestation. In a preliminary study we found that 100% of infants of 23 weeks gestation required intubation in the DR, and thus decided that such infants would be unlikely to be successfully treated with CPAP alone following delivery.[17] Others have retrospectively reported that some of these infants can be successfully managed with early CPAP, but the majority of such infants require intubation.[18]

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

Our study differs from the recently reported COIN trial14 in that we randomized all eligible ELBW infants of consenting families irrespective of whether they demonstrated spontaneous breathing, included infants of 24 weeks gestation, and compared the CPAP/permissively ventilated infants with infants who all received surfactant within 1 hour of birth. Our methodology of using early CPAP and a permissive ventilation strategy was a result of previous retrospective reviews of practice which demonstrated that the unit with the most success using CPAP also utilized a very permissive approach for intubation and the initiation of mechanical ventilation. **Error! Bookmark not defined.** We believed that testing this complete approach would be provide a more relevant result as most units currently using early CPAP also tend to be permissive in their use of intubation.

Our study has demonstrated that early CPAP and a permissive ventilator strategy when compared with surfactant given within 1 hour of birth is associated with a reduction in death or survival with BPD as defined by the need for oxygen at 36 weeks from 54% to 48%. As with any prospective randomized trial differences may exist in baseline characteristics and we noted more males in our Surfactant arm. While this difference did not reach significance, we believed that the clinical significance of this difference was relevant and chose to further adjust our results for gender which resulted in a loss of significance for our primary outcome variable using the definition of BPD as requiring oxygen at 36 weeks age. However we also noted a very significant 8% reduction in death in our 24 to 25 week strata resulting in a number needed to treat of 12.5 for each additional survivor. The 565 infants in our 24 to 25 week strata to our knowledge represents the largest prospective group of such immature infants to be randomized in any neonatal trial evaluating respiratory interventions. We believe that this lower incidence of death in these infants along with a reduction of BPD and decreased durations of ventilation and exposure to post natal steroids in the overall CPAP group represents a substantial clinical benefit compared with the initial use of early surfactant.

Our rates of BPD are higher than those reported for the COIN trial, 33.9% vs 38.9%, but the difference between the arms is very similar. The higher rates seen in our study no doubt reflect the inclusion of infants of 24 weeks gestation and the lack of inclusion of infants greater than 27 6/7ths weeks, as well as the requirement in the COIN trial that the infants demonstrate adequate spontaneous breathing at 5 minutes of life.

We prospectively identified a number of safety outcomes that we chose to follow as investigators. These included the need for compressions in the delivery room, the occurrence of severe IVH, and the incidence of airleaks, initially defined as pneumothoraces but later altered to include pulmonary interstitial emphysema, pneumomediastinum and pneumopericardium. We did not find an increase in airleaks with the use of early CPAP at 5 cm H2O.

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

The SUPPORT study was designed as a factorial design with each infant randomly receiving 2 interventions, CPAP vs Surfactant, and a lower versus higher SpO2 target range. While the study was not powered to detect an interaction between the 2 interventions, we did prospectively agree to evaluate such interactions and none were found. Both arms of the study were adequately powered for both the outcomes at neonatal discharge and the occurrence of survival NDI at 18 to 22 months and these results will be presented after all survivors have been assessed.

Conclusions:

ELBW infants between 24 and 27 6/7ths weeks gestation at birth treated with CPAP and a permissive ventilator strategy compared with the use of surfactant within 1 hour of birth and conventional mechanical ventilation have a decreased incidence of death or survival with BPD based on the need for oxygen at 36 weeks PCA with no demonstrable increase in any adverse neonatal outcomes. Early CPAP and a permissive ventilator strategy is associated with a significant reduction in mortality in the most immature infants. Surviving infants will have a complete neurodevelopmental evaluation at 18 to 22 months and these results will be separately reported.

Hi Rose
The LowSpO2 group overall actually were bigger at birth, and had less males, and we adjusted for GA, Familial clustering – we will look at the occurrence of multiples between the arms.
We then did the gender - We will work on getting the best data set and not attempt to force the ROP data at present. We agree with informing the DSMC.
We believe the most prudent approach is to rapidly report this trial to provide the best data for all other investigators. We believe that we , the investigators should be the group that informs others – Not the DSMC as this study is complete.
Neil and Wally

Subject: Re:

This is a safety issue and should go to the DSMC. For the low sat arm- are we sure that there were not confounding factors that would have raised the mortality rate such as lower GA, lower BW, more multiples or higher order multiples (as these infants may have higher mortality) that could account for the deaths?

Thanks for your thoughts.

Hi Rose
We have been reviewing the SUPPORT outcomes and we thought that you would want to know – a little distraction for you. We noted an increase in death in the Low SpO2 vs Hi SpO2 strata that was p=.07. We then ran the usual adjustments for GA, center and familial clustering and the p value was p=.0499. We the noted that there were more boys in the Hi SpO2 strata and then adjusted for gender and the p=.0378.
The ROP data is not good – too many missing values – we will try to get better info but this is not going to be clean. I think that we need to fast track a manuscript to NEJM regarding the increase

mortality in the Low SpO2 strata. We will look at causes of death. All of us think that we should do this and also discuss with the DSMC as soon as we can.

We thought you would want to know – we are still hashing this out.

Subject: RE: ROP documents

Neil,

As far as the primary outcome is concerned, in the data I sent a positive ROP outcome is defined as when both eyes meet the criteria of vessels in zone 4=Mature for one exam or in zone 3=III for two consecutive exams. A negative ROP outcome is defined as when one or both eyes has Threshold (New Type I) ROP as recorded on the SUPP10, has ROP stage 4 or 5, or has surgery for ROP.

The reason I sent such detailed data is that we need to review the exam data for inconsistencies or "red flags" that would cause us to doubt that the data are correct. For example, if one eye has lowest zone of any vessels of 4=Mature and the other eye has ROP stage 4, we would probably want to query that site to see if a typo had been made. As I look at the data I sent you all, I can see multiple instances where there are such inconsistencies that need to be cleared up. But, I am not an expert on ROP, so I know that I will not be able to identify all potential problems on my own. I will need other eyes to review the data so that we can put together queries to send the centers.

Thanks, everyone, for your help in this. I know it's a lot to look at, but it will help us ensure that our primary outcome data are as clean as possible.

Subject: RE: ROP documents

Hi Marie
We are looking at the crosstabs and will send a final answer in an hour or so. Overall we should resolve any discrepancies but for timing etc – unless the difference indicates that the intervention was done as per protocol or not, then such discrepancies are not worth resolving
The ROP data is obviously based on Dales very detailed input. However, lets look at how we are defining ROP – either threshold or surgery –
I assume that for any child, a single eye involvement is sufficient to meet this primary and concordance between the eyes is of interest but not for the primary.
The definition of the Threshold ROP is as follows:
Threshold (New Type I) ROP
Threshold (New Type I) ROP is defined as:
• In Zone II: plus disease with stage 2 or stage 3
• In Zone I: plus disease with any stage ROP, or stage 3 without plus disease

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

I can't see where it was said or not but are you working on the assumption that an infant has ROP if they meet the criteria or had surgery on any eye or are you looking at both eyes. For me, it would be any eye in a child that meets the definition of Threshold, whether the other eye meets this or not and the same for surgery.
Much of the data that you sending I believe is for more secondary outcomes to look at more detail than is needed or wanted for the Primary. Is this also your understanding of this issue?

Subject: ROP documents

Hi all,

Please find attached four ROP documents for your review (described below). Before we do the ROP analysis, we will need to clean the ROP data as we have been doing for BPD. This will likely involve sending out a batch of queries for the centers to resolve inconsistencies within and between forms. As I am less familiar with ROP than I am with the BPD outcomes, I will need your help to identify inconsistencies that need to be resolved. The attached documents were created in order to facilitate that process. Perhaps we can review them together during our meeting on Monday.

1) **SUPP10 ROP cross-tabs (all exams) 8-27-09.rtf** – This document contains cross-tabulations of ROP data for all exams entered on the SUPP10. The purpose of this document is to help identify any inconsistent data within the exams.
2) **Current and previous exam results by ROP reason 8-27-09.rtf** – For all infants with a final ROP determination, selected data from the current exam (from which the ROP determination was made) and the previous exam for the infant are presented. Additional information included are the estimated PMA at the time of the current exam and the number of days between the current and previous exam. The purpose of this document is to help identify cases where the change in ROP data between exams seems unreasonable for the amount of time that elapsed between the exams.
3) **Cases where ROP status changed per SUPP10 8-27-09.rtf** – This document lists data from each ROP exam for infants whose final ROP status appears to have changed over time (final status was positive but changed to negative at a subsequent exam or vice versa). The purpose of this document is to determine whether or not the changes in status seem reasonable.
4) **ROP on NG03 vs SUPP10 8-27-09.rtf** – This document contains cross-tabulations of similar data fields on the NG03 and SUPP10. Note that only SUPP10 exams that occurred by the date of NG03 status are included in this comparison. Because ROP exam dates are not entered on the NG03, and it is therefore not clear precisely which exams were consulted when the NG03 data were entered, it may be difficult to compare the data on these two forms.

Neil and Wade, have you had a chance to look over the proposed cross-form queries I sent you on 8/18? As these queries involve many important data elements, including treatment variables like intubation/surfactant and outcomes like air leaks and IVH, we need to have these inconsistencies resolved before we finalize the SUPPORT manuscripts. If at all possible, I would like to send these

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

queries to the centers by the end of next week. As I told everyone when we planned the analysis meeting, I will be out of town September 5-20, so it would be nice if the centers could be working on the queries during that time.

For the meeting on Monday, I will have my analysis datasets for BPD, ROP and other outcomes available for review. Please let me know if there is anything else of high-priority for me to prepare for Monday. Time is obviously limited, but I will try to accommodate.

I look forward to reviewing the SUPPORT data with you next week.

Thanks,
Marie

Dear Neil, Rosemary, Rich, Abhik, Kristin, and Marie:

Enclosed is a first draft of the oxygen saturation paper. The Introduction and Methods are complete. I have not worked on the rest of the pending results and/or interpretation of them.

See you on Wednesday.

Subject: RE: ROP documents

Neil,

As far as the primary outcome is concerned, in the data I sent a positive ROP outcome is defined as when both eyes meet the criteria of vessels in zone 4=Mature for one exam or in zone 3=III for two consecutive exams. A negative ROP outcome is defined as when one or both eyes has Threshold (New Type I) ROP as recorded on the SUPP10, has ROP stage 4 or 5, or has surgery for ROP.

The reason I sent such detailed data is that we need to review the exam data for inconsistencies or "red flags" that would cause us to doubt that the data are correct. For example, if one eye has lowest zone of any vessels of 4=Mature and the other eye has ROP stage 4, we would probably want to query that site to see if a typo had been made. As I look at the data I sent you all, I can see multiple instances where

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

there are such inconsistencies that need to be cleared up. But, I am not an expert on ROP, so I know that I will not be able to identify all potential problems on my own. I will need other eyes to review the data so that we can put together queries to send the centers.

Thanks, everyone, for your help in this. I know it's a lot to look at, but it will help us ensure that our primary outcome data are as clean as possible.

Subject: RE: ROP documents

Hi Marie
We are looking at the crosstabs and will send a final answer in an hour or so. Overall we should resolve any discrepancies but for timing etc – unless the difference indicates that the intervention was done as per protocol or not, then such discrepancies are not worth resolving
The ROP data is obviously based on Dales very detailed input. However, lets look at how we are defining ROP – either threshold or surgery –
I assume that for any child, a single eye involvement is sufficient to meet this primary and concordance between the eyes is of interest but not for the primary.
The definition of the Threshold ROP is as follows:
Threshold (New Type I) ROP
Threshold (New Type I) ROP is defined as:
• In Zone II: plus disease with stage 2 or stage 3
• In Zone I: plus disease with any stage ROP, or stage 3 without plus disease
I can't see where it was said or not but are you working on the assumption that an infant has ROP if they meet the criteria or had surgery on any eye or are you looking at both eyes. For me, it would be any eye in a child that meets the definition of Threshold, whether the other eye meets this or not and the same for surgery.
Much of the data that you sending I believe is for more secondary outcomes to look at more detail than is needed or wanted for the Primary. Is this also your understanding of this issue?
Neil

Subject: ROP documents

Hi all,

Please find attached four ROP documents for your review (described below). Before we do the ROP analysis, we will need to clean the ROP data as we have been doing for BPD. This will likely involve sending out a batch of queries for the centers to resolve inconsistencies within and between forms. As I am less familiar with ROP than I am with the BPD outcomes, I will need your help to identify inconsistencies that need to be resolved. The attached documents were created in order to facilitate that process. Perhaps we can review them together during our meeting on Monday.

1) **SUPP10 ROP cross-tabs (all exams) 8-27-09.rtf** – This document contains cross-tabulations of ROP data for all exams entered on the SUPP10. The purpose of this document is to help identify any inconsistent data within the exams.
2) **Current and previous exam results by ROP reason 8-27-09.rtf** – For all infants with a final ROP determination, selected data from the current exam (from which the ROP determination was made) and the previous exam for the infant are presented. Additional information included are the estimated PMA at the time of the current exam and the number of days between the current and previous exam. The purpose of this document is to help identify cases where the change in ROP data between exams seems unreasonable for the amount of time that elapsed between the exams.
3) **Cases where ROP status changed per SUPP10 8-27-09.rtf** – This document lists data from each ROP exam for infants whose final ROP status appears to have changed over time (final status was positive but changed to negative at a subsequent exam or vice versa). The purpose of this document is to determine whether or not the changes in status seem reasonable.
4) **ROP on NG03 vs SUPP10 8-27-09.rtf** – This document contains cross-tabulations of similar data fields on the NG03 and SUPP10. Note that only SUPP10 exams that occurred by the date of NG03 status are included in this comparison. Because ROP exam dates are not entered on the NG03, and it is therefore not clear precisely which exams were consulted when the NG03 data were entered, it may be difficult to compare the data on these two forms.

Neil and Wade, have you had a chance to look over the proposed cross-form queries I sent you on 8/18? As these queries involve many important data elements, including treatment variables like intubation/surfactant and outcomes like air leaks and IVH, we need to have these inconsistencies resolved before we finalize the SUPPORT manuscripts. If at all possible, I would like to send these queries to the centers by the end of next week. As I told everyone when we planned the analysis meeting, I will be out of town September 5-20, so it would be nice if the centers could be working on the queries during that time.

For the meeting on Monday, I will have my analysis datasets for BPD, ROP and other outcomes available for review. Please let me know if there is anything else of high-priority for me to prepare for Monday. Time is obviously limited, but I will try to accommodate.

I look forward to reviewing the SUPPORT data with you next week.

Thanks,
Marie

Abstract

Background: The most appropriate initial and ongoing respiratory support for the extremely low birthweight infant (ELBW) has not been established by adequate prospective evidence. The current usual approaches include the early use of continuous positive airway pressure (CPAP) or the early administration of surfactant following endotracheal intubation. No study to date has compared these approaches in a large population of ELBW infants

Methods: The SUPPORT study was a randomized multicenter trial that enrolled consented preterm infants of 24 0/7ths weeks to 27 6/7ths weeks by best obstetrical within 2 prospective strata, 24 to 25 6/7ths weeks, and 26 to 27 6/7th weeks. Infants randomized to CPAP were treated with CPAP initiated in the delivery room and continued following admission to the NICU and such infants could be intubated if they met prespecified criteria including an FiO2 >.50 required to maintain an indicated SpO2 > 88% for one hour, an arterial PaCO2 > 65 torr , and/or hemodynamic instability defined as a low blood pressure for gestational age and/or poor perfusion, requiring volume and/or pressor support for a period of 4 hours or more. Infants randomized to surfactant were intubated and received surfactant within 60 min minutes of birth. Criteria for extubation differed between the 2 groups with the CPAP infants treated using a permissive strategy allowing higher PaCO2s and extubation at higher ventilator settings. All infants were also randomized to one of 2 ranges of SpO2 while in the NICU and receiving supplemental oxygen, a low target range of 85% to 89% and a high target range of 91% to 95% using specifically altered blinded oximeters.

Results: The study enrolled 1316 infants from February 2005 to February 2009. There were 565 infants enrolled in the lower gestational age strata, and 751 in the higher strata. There were no significant differences for sex, birth weight, APGAR scores or race between the 2 groups. There were no differences between the groups in the receipt of any or a full course of antenatal steroids, or compressions in the DR, whereas the Surfactant group received significantly more epinephrine in the delivery room (4% vs 2%, p=0.022). In the delivery room, 66% of the CPAP infants received positive pressure ventilation compared with 93% of the surfactant infants, and surfactant was given to 14% of the CPAP versus 51% of the surfactant group, and 67% of the CPAP infants received surfactant at any time during their hospitalization, (all p<0.001). There were no differences overall for death in the delivery room or death during the hospitalization, nor any differences in length of stay, or days of oxygen for survivors, and the need for oxygen at discharge. More CPAP infants were alive and off mechanical ventilation by day 7, (p=0.015). There were no differences between the groups for airleaks including penumothoraces, and no

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

differences for medical or surgical NEC, PDA requiring surgery, or severe IVH. All infants in the Surfactant arm were intubated, compared with only 77% of the CPAP infants required intubation during their nursery course, ($p<0.001$). There was a significant reduction in the use of postnatal steroids for BPD in the CPAP infants compared with the Surfactant infants , 7% vs 13%, $p=0.0004$). The primary outcome of death or BPD, defined as the need for supplemental oxygen at 36 weeks post conceptional age was 48% versus 54%, ($p = 0.035$, $p= 0.042$ when adjusted for gestational age, center and familial clustering). There was a significantly higher mortality (32% vs 24%, $p=0.026$) in the 24 to 25 weeks strata for the infants in the Surfactant arm.

Conclusions: The use of early CPAP with a permissive ventilator strategy results in a decrease in death or survival with BPD defined as the need for oxygen at 36 weeks post conceptional age compared with the use of surfactant within 1 hour of birth and a conventional mechanical ventilation approach. There were no increased adverse outcomes in the CPAP group, and the surviving infants will be followed for a complete neurodevelopmental assessment at 18 to 22 months. Early CPAP and the use of a permissive ventilator strategy is an evidence based approach for the initial respiratory support of the ELBW infant.

Introduction:

At the present time, there is no recommendation or standard teaching regarding the early use of CPAP/PEEP during resuscitation and continuing after NICU admission for the extremely low birth weight (ELBW) infant. However, a number of studies, mostly retrospective in nature, have suggested that the use of early CPAP may be associated with improved outcomes, including a decreased need for mechanical ventilation, a decreased need for surfactant therapy, and a decrease in oxygen supplementation and/or death at 28 days after birth and at 36 weeks post menstrual age. There has not been a prospective study which has randomized ELBW infants to CPAP/PEEP beginning in the delivery room, and continuing in the NICU and a permissive ventilation strategy if intubation is required and compared their outcomes to infants treated with prophylactic or early natural surfactant, interventions with known efficacy in reducing mortality, severity of disease and the incidence of chronic lung disease (CLD).

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

Positive End Expiratory Pressure (PEEP) has been shown to be of benefit in maintaining functional residual capacity (FRC). Although no formal recommendation has been made to date about maintaining PEEP in the delivery room setting, continuous positive airway pressure appears beneficial during cardiopulmonary resuscitation[1]. Gregory et al in 1971 first demonstrated that the use of CPAP started at approximately 5.9hours (+12.4hrs) for their infants < 1500 gm at birth, improved oxygenation[2] in newborn infants with respiratory distress; these observations were followed by prospective studies that demonstrated improved survival in premature infants treated with early CPAP[3]. Premature infants who do not achieve a FRC are more likely to develop hyaline membrane disease (HMD) requiring mechanical ventilation.[4] CPAP may prevent the excessive consumption of surfactant in newborn infants with limited surfactant production.[5] A review of prospective studies evaluating early (not delivery room) CPAP in the pre-surfactant, pre-antenatal steroid era found that early CPAP improved survival overall and for infants greater than 1500 gm, and was associated with increased pneumothoraces.[6] A more recent review of prophylactic CPAP started in the delivery room reviewed only 2 available trials and found no significant difference between the CPAP and conventionally managed infants and noted a trend to increased adverse outcomes for the CPAP treated infants.[7] These authors concluded that there was insufficient evidence to evaluate the use of prophylactic nasal CPAP in preterm infants.

There is substantial retrospective evidence suggesting a benefit for early CPAP in experiences from the USA. A survey of eight neonatology units in the USA in 1987 demonstrated that one unit, Columbia, which preferentially utilized early CPAP had the lowest rate of CLD when compared to other units. [8] More recent comparisons of practices and outcomes between two neonatology units in Boston and the Babies and Children's Hospital unit (Columbia) evaluated VLBW infants born in 1991 to 1993 and with units in Stockholm which also used early CPAP . demonstrated that the units using early CPAP had less CLD or less oxygen dependency at 40 weeks postconceptional age. [910] Similar observations were reported by a number of other European centers who noted a decrease in the need for mechanical ventilation among their very preterm infants without an increase in morbidity following the initiation of early CPAP treatment.[111213]

The recent COIN trial randomized 610 infants from 25 weeks 0 days to 28 weeks 6 days gestational age at birth, who were able to breathe at 5 minutes of age, and had evidence of respiratory distress at that time. Infants were randomized to either intubation and ventilation or CPAP received 8 cm H20. CPAP infants were intubated if they met failure criteria.[14] This study did not compare early CPAP to the early administration of surfactant, and surfactant use followed unit standard of care. The results demonstrated that there was no difference between the groups for the outcome of death or BPD by the need for oxygen at 36 weeks. There was a significant primary increase in the occurrence of pneumothoraces in the CPAP group, most

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

occurring within the first 2 days (9.1% vs 3.0%, p=.001), consistent with the findings of an earlier meta analyses6 and a reduction in death or the need for oxygen at 28 days in the CPAP infants (odds ratio, 0.63; 95% CI, 0.46 to 0.88; P=0.006) .

At the present time there are no studies in the surfactant and antenatal steroid era which have prospectively compared early CPAP with the use of prophylactic or early surfactant and conventional ventilation. The current available evidence demonstrates that prophylactic natural surfactant treatment significantly decreases mortality, air leak, and BPD in preterm infants.[15] Early surfactant, defined as surfactant at less than 2 hours of life is also of benefit and reduces air leaks, and mortality.[16] Overall surfactant has not been reported to significantly reduce BPD, but may do so for the most immature infants.[17] In addition surfactant has not been found to significantly reduce subsequent neurodevelopmental impairment (NDI), but has reduced death and not been associated with increased NDI in such survivors.

In view of the current interest in the use of early CPAP and the lack of prospective comparisons of this approach with the evidence based intervention of prophylactic or early surfactant, the SUPPORT study was designed to compare these approaches for the most preterm infants. We also randomized infants to 2 ranges of pulse oximetry targets during their exposure to oxygen using a factorial design, and the results for the oximetry study will be reported separately.

Methods

This was a prospective, randomized, factorial 2X2 design multi-center trial conducted by the NICHD Neonatal Research Network. This report describes the prospective comparison of CPAP and a permissive ventilatory strategy begun in the delivery room and continuing in the NICU with early (< 1 hour) surfactant and mechanical ventilation.

Infants were also randomized to a prospective comparison of a lower SpO2 range (85% to 89%) with a higher more conventional SpO2 range (91% to 95%) until the infant was no longer requiring ventilatory support using purpose altered oximeters. These results will be separately reported.

The primary hypothesis of this study was that relative to infants managed with prophylactic/early surfactant and conventional ventilation that the use of early CPAP and a permissive ventilatory strategy in infants of less than 28 weeks gestation with continuing CPAP in the NICU will result in an increased survival without BPD at 36 weeks.

Eligible infants were 24 0/7ths to 27 6/7th weeks at birth by best obstetrical estimate, born at the randomizing center, for which a decision has been made to provide full resuscitation as

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

required without known malformations, and for whom parental consent had been obtained, with 2 randomization strata, infants of 24 0/7ths to 25 6/7ths weeks, and infants of 26 0/7ths-27 6/7ths weeks.

CPAP Arm - Delivery room management: A T-piece resuscitator, a neonatal ventilator, or an equivalent CPAP methodology was used at all sites for the delivery room administration of CPAP. CPAP or ventilation with PEEP was utilized if the infant requires positive pressure during resuscitation. CPAP was continued until admission to the NICU using the Neopuff or equivalent device and a face mask or nasal prongs. CPAP infants were not to be intubated for surfactant only in the DR, and CPAP infants who required intubation for resuscitation were to receive surfactant within 60 minutes of birth. Intubation for these infants was performed only for the standard NRP indications including failure to respond to positive pressure ventilation (PPV) with evidence of continuing cyanosis or bradycardia, the need for chest compressions, the need to administer intratracheal medications, or other situations in which the resuscitation team determines that surfactant is urgently required.

NICU management: Intubation was performed at any time for the occurrence of repetitive apnea requiring bag and mask ventilation, clinical shock, sepsis, and/or the need for surgery . While intubation was never required by protocol, CPAP infants could be be intubated if they meet ***ANY*** *of* the following criteria: an FiO_2 >.50 required to maintain an indicated SpO2 $\geq$ 88% for one hour, an arterial $PaCO_2$ > 65 torr documented on a single blood gas, or hemodynamic instability defined as a low blood pressure for gestational age and/or poor perfusion, requiring volume and/or pressor support for a period of 4 hours or more. If intubated within the first 48 hours of life infants were to receive surfactant.

Extubation for CPAP infants was to be attempted within 24 hours if ALL of the following criteria were met: a PaCO2 < 65 torr with a pH > 7.20, an SpO2 > 88% with an FiO2 < 50% , a mean airway pressure (MAP) < 10 cm H2O, ventilator rate < 15 bpm, an amplitude < 2X MAP if on high frequency ventilation (HFV), and hemodynamically stable, and without a clinically significant patent ductus arteriosus. Re-intubation criteria were the same as those for Intubation for the CPAP infants. After 3 intubations CPAP infants were treated using NICU standard of care.

Surfactant Arm: All such infants were to be intubated within 1 hour of life and receive surfactant, followed by continued ventilation. All infants were to be extubated within 24 hours of meeting all of the following criteria: $PaCO_2$ < 50 torr and pH > 7.30 An FiO2 ≤ 35 with a SpO2 > 88%, a mean airway pressure (MAP) < 8 cm H_2O, ventilator rate $\leq$ 15 bpm, an amplitude < 2X MAP if on high frequency ventilation (HFV), and be hemodynamically stable with no evidence of clinically significant PDA. Once extubated Surfactant infants were treated using NICU standard of care.

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

These criteria were in effect for the first 14 days of life, following which the infant was treated as per NICU standard of care. For both arms of the trial intubation could be performed at any time for the occurrence of repetitive apnea requiring bag and mask ventilation, clinical shock, sepsis, and/or the need for surgery.

Randomization was stratified by gestational age group, utilizing specially prepared double-sealed envelopes. Deliveries were randomized as a unit, and thus multiples, were randomized to the same arm of the trial.

Hypothesis and sample size: We hypothesized that early CPAP would reduce the incidence of death or survival with BPD at 36 weeks, and the occurrence of death or survival with neurodevelopmental handicap at 18 to 22 months by 10% using the NRN occurrence of these outcomes for infants born in 2000. We increased the sample size by a factor of 1.12 to allow for multiples to be randomized to the same treatment as this introduced a clustering effect into the design, and increased the sample sizes by 17% to adjust for attrition after discharge and before follow-up. This resulted in a sample size of 1312 infants. This sample size was not large enough to determine an interaction effects between the 2 factorial arms.

In addition there was a prospective decision to also evaluate the occurrence of BPD using the Physiologic Definition which required an attempt at oxygen withdrawal for infants who required < 30% oxygen at 36 weeks and assigned a diagnosis of BPD to any infant who required more than 30% oxygen at 36 weeks or who required positive pressure support. [1819]

The study was approved by Human Subjects Committees at all participating sites and RTI, the data center, and parental consent was required before delivery.

Results:

There were 1361 infants enrolled in this trial from Jan 1 2004 through to Mar 1 2009. The trial was temporarily suspended by the DSMB because of concerns regarding the oximetry data in November 2005 but after a complete review the trial was continued in February 2006 (Check dates) with no protocol changes. The patient descriptive information for the CPAP versus Early Surfactant arms is shown in Table 1.There were 565 infants enrolled in the lower gestational age strata, and 751 in the higher strata. There were no significant differences for sex, birth weight Apgar scores or race between the 2 groups, although there were more boys in the CPAP arm. In addition there were no differences in the maternal receipt of any or a full course of antenatal steroids, or compressions in the DR, whereas the Surfactant group received significantly more epinephrine in the delivery room and had a higher DR mortality which was not significant.

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

In the delivery room, 66% of the CPAP infants received positive pressure ventilation compared with 93% of the surfactant infants, and surfactant was given to 14% of the CPAP versus 51% of the surfactant group, and 67% of the CPAP infants received surfactant at any time during their hospitalization, (all $p<0.0001$). Intubation in the DR occurred in 34% of CPAP infants compared with 93% of surfactant infants, $p<0.0001$.

The primary outcome of death or BPD, defined as the need for supplemental oxygen at 36 weeks post conceptional age was significantly lower for the CPAP group compared with the Surfactant group, 48% versus 54%, ($p = 0.0354$, $p= 0.0424$ when adjusted for gestational age, center and familial clustering). Using the Physiologic Definition for BPD there was a non-significant decrease in the occurrence of BPD in the CPAP group (39% vs 41%, p=.63), and a non-significant reduction in the occurrence of death or Physiologic BPD at 36 weeks in the CPAP group, (48% vs 51%, p=.248)

There were no differences overall for death in the delivery room or death during the hospitalization, nor any differences in length of stay, or days of oxygen for survivors, and the need for oxygen at discharge. (Table 2). More CPAP infants were alive and off mechanical ventilation by day 7, ($p=0.0149$). We prospectively recorded air leaks in the first 14 days and there were no differences between the groups, and no differences for medical or surgical NEC, PDA requiring surgery, severe IVH or airleaks during the hospital stay. All infants in the Surfactant arm were intubated, compared with 83% of the CPAP infants who required intubation during their nursery course, ($p<0.0001$). There was a significant reduction in the use of postnatal steroids for BPD in the CPAP infants compared with the Surfactant infants, 7% vs13%, $p=0.0004$).

Strata Results: 24 – 25 weeks Gestation

There were significantly more non-Hispanic black infants in the CPAP group compared with the Surfactant group and no other differences noted in the DR for death, the need for compressions and epinephrine, and no difference in the mothers receipt of antenatal steroids. The other differences are shown in Table 3 (24-25 wk Strata). There was a significantly higher mortality (32% vs 24%, $p=0.0264$), and a significantly higher exposure to postnatal steroid for BPD, 21% vs 13%, $p=0.0198$) for the Surfactant infants compared with the CPAP group, with no differences for any other clinical outcomes including air leaks. As with the overall groups there were more infants alive and off mechanical ventilation at 1 week in the CPAP infants of this strata.

26-27 weeks Gestation

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

There was no difference in mortality for the CPAP vs Surfactant groups, 10% vs 11%. The CPAP infants required fewer days of oxygen, 36.8 vs 46.5, p=0.0097, lesser days of mechanical ventilation, 10.7 vs 14.2, p=0.0068, and less postnatal steroids for BPD, 3% vs 8%, p=0.0027.

Discussion:

This is the first large multicenter study to prospectively compare early CPAP, with early surfactant given within an hour of life to a large group of ELBW infants. There have been many retrospective cohort reviews suggesting that early CPAP reduced the occurrence of BPD without increasing other morbidities.[20] More recent experiences also suggest that there may an increase in retinopathy of prematurity with the early use of bubble CPAP.[21] The current trial is the largest study reported to prospectively compare CPAP and Surfactant for the ELBW infant and the only study to include infants of 24 weeks gestation. In a preliminary study we found that 100% of infants of 23 weeks gestation required intubation in the DR, and thus decided that such infants would be unlikely to be successfully treated with CPAP alone following delivery.[22] Others have retrospectively reported that some of these infants can be successfully managed with early CPAP, but the majority of such infants require intubation.[23] Our study differs from the recently reported COIN trial14 in that we randomized all eligible ELBW infants of consenting families irrespective of whether they demonstrated spontaneous breathing, included infants of 24 weeks gestation, and compared the CPAP/permissively ventilated infants with infants who all received surfactant within 1 hour of birth. Our methodology of using early CPAP and a permissive ventilation strategy was a result of previous retrospective reviews of practice which demonstrated that the unit with the most success using CPAP also utilized a very permissive approach for intubation and the initiation of mechanical ventilation, and we felt that testing this complete approach would be provide a more relevant result as most units currently using early CPAP also tend to be permissive in their use of intubation. Indeed the actual study sites varied greatly in the prestudy practices with many already having adopted an early CPAP approach. All centers agreed to the protocol, and we followed all study protocol violations. The commonest problems were the failure to give surfactant within the first hour to both the Surfactant infants (n=30) and CPAP infants who were intubated (n=34).

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

Our study has demonstrated that early CPAP and a permissive ventilator strategy when compared with surfactant given within 1 hour of birth is associated with a reduction in death or survival with BPD as defined by the need for oxygen at 36 weeks from 54% to 48%. These occurrences are higher than those reported for the COIN trial, 33.9% vs 38.9%, but the difference between the arms is very similar. The higher rates seen in our study no doubt reflect the inclusion of infants of 24 weeks gestation and the lack of inclusion of infants greater than 27 6/7ths weeks, as well as the requirement in the COIN trial that the infants demonstrate adequate spontaneous breathing at 5 minutes of life. Our study had more infants in our large strata (751) than any previously reported retrospective or prospective study of the use of CPAP and the 565 infants in our 24 to 25 week strata represents the largest prospective group of such immature infants to be randomized in any neonatal trial comparing respiratory outcomes.

We prospectively identified a number of safety outcomes that we chose to follow as investigators. These included the need for compressions in the delivery room, the occurrence of severe IVH, and the incidence of airleaks, initially defines as pneumothoraces but later altered to include pulmonary interstitial emphysema, pneumomediastinum and pneumopericardium. These results were provided for the total group of enrolled infants, not by study assignment, and were compared to the occurrence of these outcomes using the generic database of the Neonatal Research Network for 2002 to 2004 for infants of 24 to 27 weeks gestation preceeding the initiation of the study. The investigators agreed that as long as these occurrences were within the previous rates that there would minimal concern and the DSMB at all times had full access to all information including these occurrences by randomized group. We did not find any significant increase in these outcomes.

Subject: Data requests, tracking, etc re: SUPPORT neuroimaging

Hi Meg, Qing, Jenny, Jamie, Rose, Abhik,

With the second central US reading for SUPPORT just completed, we now need to tackle the issue of what we have completed, what we have left to do, what is missing, etc. We need this to plan how the rest of the CUS readings will be done, the timeline, and analysis plans. **I would like for us to have something completed for late breakers PAS - and I think realistically we need to say all readings must be done and input by beginning of November, providing we have been inputting the central reader data as it comes in.** (And also provided we start data cleaning and plan for analysis strategy.)

In addition, thinking about how we will wrap up the neuroimaging readings and analysis has reminded me to ask a separate series of questions about the 18-22 mo follow-up and school-age follow-up.

So here it goes -

1) Characterization of CUS studies: expected, done, left to do, plans for remaining reading.

a. In order to plan how many days we need to read with Dr. Bulas and Dr. Slovis, we will need the following info:

i. How many total CUS are expected in the entire study? (All MRI01 forms should be submitted by now, so we should know this number at this point.)

ii. Are any of these "expected" CUS still not sent to RTI by the sites?

iii. How many CUS were read in the first central reading by DB, how many by TS?

iv. How many total CUS were read in the second central reading by DB, how many by

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

TS?

v. How many patients have BOTH early and late CUS? How many of these have been completely read by both DB and TS?

vi. How many have COMPLETE neuroimaging (early CUS, late CUS, MRI)

b. Of course we want every CUS we can get, but the most important group for the study as a whole is the group that has all neuroimaging. So, we should be most aggressive about getting the CUS that are missing in that group.

2) Setting up more readings

a. As we discussed at the central reading, we should **move forward now with arranging separate dates for RTI to go out to Dr. Slovis and Dr. Bulas to finish up** the readings- and I think Meg may already be looking at dates for her and Amanda to vist with Dr. Bulas. I believe Julie will be going out to see Dr. Slovis? In any case, I recommend nailing down a FEW DATES NOW for the next 4 -6 weeks (even if it is a day here and a day there).

3) More data requests, but related to above questions:

a. The big spreadsheet Meg has and I want: Meg has a very nice spreadsheet with what I believe is ALL patients who were enrolled in SUPPORT Neuroimaging who have ANY CUS. Could I have an updated version of that electronically?

i. Will the "updated version" I receive be final and complete? In other words, will all the MRI01 data be in by now.

ii. Also, that spreadsheet indicates if Early or Late US and MRI were doneŠbut not whether they have been received. I really don't want to make that spreadsheet more cumbersome, so don't add columns, you can just answer 1.b above.

b. "MasterMRIFU" data sheet: Jenny Auman made a really nice spreadsheet for me with all sorts of information pertinent to the neuroimaging and follow-up issues. Jenny - could I have an updated version? **I am attaching the June 10 version just to show you which spreadsheet I mean.**

c. Pertinent to questions 1.f - looking at the June 10 version of the MasterMRIFU list, it seems that there are only 12 patients with an early CUS and a successful MRI, but NO late CUSŠthis is a group (and of course there may be more than 12 now) that we should really try to understand. As I said above, the most important group we should focus on is the group that have ALL neuroimaging, so if they are missing a late CUS but they actually have one somewhere, we should try to snag it.

4) Tracking for extended follow-up - I know a lot of questions will come up about the details of this and the $$ involved as we move toward the follow-up of this group. So here are a few questions and comments -

a. REMINDERS to sites? As you know, we did remind PI's about the 3-4 year tracking for the school age follow-up on the FU PI conference call. However, can we do something more formal - or are you already doing that? Can you - or are you already planning to - send out an email 3 months before the 3-4 year window opens to remind about the form, then again at 3 _ years IF the form is not yet completed? I know that sites don't like to be "bugged", but if they understand that tracking reimbursement is LINKED to completion of that form, it may be better tolerated.

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

i. BTW, from the MasterMRIFU spreadsheet I think we have **68 or 69 subjects who have already have their window open for 3-4 year tracking! 9 or 10 patients will have that window CLOSED by the end of this month!** Are the tracking forms in on those yet?

b. $$ for tracking between 18-22 months and 3-4 years: Rose, can you tell me how much was the FINAL budgeted for the contacts between 18-22 months and 3-4 years? We had said in the original budget that it would be 2 one-hour contacts at $35/hr, but I think that was revised upward. Also, from a process perspective, when are those funds released to sites? As soon as they complete the 3-4 year tracking form? Or when the patient will reach 3-4 years IF the tracking form has been completed?

c. How will the later tracking funds will be distributed and contact attempts "verified"? In the protocol, we originally budgeted four 2 hour tracking contacts (total 8 hours of tracking contact at $35/hr) for tracking between 3-4 years and the school age follow-up visit. We now have a mechanism in place to "track the tracking" at 3-4 years. But what should we do for tracking between 3-4 and the school age visit? Just a reminder email at 5 _ years? And are we just distributing the tracking funds without "verification"?

5) Data "cleaning" and analysis:

a. Qing - we could probably start talking about starting some data clean up and setting up analyses so we can be ahead of the game.

i. I have a few ideas for cleaning up the data. For instance, we will need to look at "normal" and make sure there really are NO things marked on the form or comments made. Also, we will need to search the comments for any mention of cerebellar or cerebellum because some abnormalities in that area were not so easily categorized. Also a few other things, but I will make a list of things I am thinking about, and you can also tell me what you think.

ii. As for how we will look at the data and prelim analysis - should I put together some mock data tables?

Thanks again all! I am sure I have forgotten a lot, but that's it for now.

THANKS for all your help and great work!

Susan

fax: 650-725-8351

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

1) Characterization of CUS studies: expected, done, left to do, plans for remaining reading.

a. In order to plan how many days we need to read with Dr. Bulas and Dr. Slovis, we will need the following info:

i. How many total CUS are expected in the entire study? (All MRI01 forms should be submitted by now, so we should know this number at this point.)

We still have 10 missing MRI01 forms and they've been reported to the Centers as such. However, we currently have 676 patients enrolled, 652 with an Early US reported and 571 with a Late US reported.

ii. Are any of these "expected" CUS still not sent to RTI by the sites?

Yes, I am waiting on:
3 early HUS from UCSD
5 early HUS and 3 late HUS from Dallas – Nancy Miller is working to track them down
1 early and late from Houston that was a problem at the last reading, I have emailed her
1 early and late from UAB that was a problem at the last reading, I have emailed her

iii. How many CUS were read in the first central reading by DB, how many by TS?

For the first reading,

Reader Initials	TotalRead
Db	433
Ts	425

iv. How many total CUS were read in the second central reading by DB, how many by TS?

Can't do this until the forms are keyed, I anticipate the keying to take 3 weeks, however, I sent you rough numbers and I estimate:
DB=458
TS=346

v. How many patients have BOTH early and late CUS? How many of these have been completely read by both DB and TS?

Per the keyed MRI01 forms at this point (10 still pending), 568 patients have both an early and late US. The second question can't be answered until all the most recent set of MRI04 forms are keyed.

vi. How many have COMPLETE neuroimaging (early CUS, late CUS, MRI)

Per the keyed MRI01 forms at this point (10 still pending), 542 patients have all three images. There is one patient with missing codes in the MRI date, so Jenny will investigate what happened with that one.

b. Of course we want every CUS we can get, but the most important group for the study as a whole is the group that has all neuroimaging. So, we should be most aggressive about getting the CUS that are missing in that group.

2) Setting up more readings

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

a. As we discussed at the central reading, we should **move forward now with arranging separate dates for RTI to go out to Dr. Slovis and Dr. Bulas to finish up** the readings- and I think Meg may already be looking at dates for her and Amanda to vist with Dr. Bulas. I believe Julie will be going out to see Dr. Slovis? In any case, I recommend nailing down a FEW DATES NOW for the next 4 -6 weeks (even if it is a day here and a day there).

Amanda and Meg will be at Children's on September 14th to read with Dorothy and hopefully finish up with her. We may need on additional 4 hour block and we will set up a second time with Dorothy.

For Tom in Detroit, we will need one longish trip out there to finish up, Meg and Julie plan to go out there October 25-27. I will also have him block a couple days in early November if needed.

3) <u>More data requests, but related to above questions</u>:
a. The big spreadsheet Meg has and I want: Meg has a very nice spreadsheet with what I believe is ALL patients who were enrolled in SUPPORT Neuroimaging who have ANY CUS. Could I have an updated version of that electronically?

We will send in a couple of weeks when it is updated.

i. Will the "updated version" I receive be final and complete? In other words, will all the MRI01 data be in by now.

We still have 10 MRI forms pending.

ii. Also, that spreadsheet indicates if Early or Late US and MRI were done but not whether they have been received. I really don't want to make that spreadsheet more cumbersome, so don't add columns, you can just answer 1.b above.

Meg will send you something shortly.

b. "MasterMRIFU" data sheet: Jenny Auman made a really nice spreadsheet for me with all sorts of information pertinent to the neuroimaging and follow-up issues. Jenny - could I have an updated version? **I am attaching the June 10 version just to show you which spreadsheet I mean.**

Jenny sent this to Susan on 8/26.

c. Pertinent to questions 1.f - looking at the June 10 version of the MasterMRIFU list, it seems that there are only 12 patients with an early CUS and a successful MRI, but NO late CUSŠthis is a group (and of course there may be more than 12 now) that we should really try to understand. As I said above, the most important group we should focus on is the group that have ALL neuroimaging, so if they are missing a late CUS but they actually have one somewhere, we should try to snag it.

Meg has queried the centers about these and will let you know when she hears back.

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

4) Tracking for extended follow-up - I know a lot of questions will come up about the details of this and the $$ involved as we move toward the follow-up of this group. So here are a few questions and comments -

a. REMINDERS to sites? As you know, we did remind PI's about the 3-4 year tracking for the school age follow-up on the FU PI conference call. However, can we do something more formal - or are you already doing that? Can you - or are you already planning to - send out an email 3 months before the 3-4 year window opens to remind about the form, then again at 3 _ years IF the form is not yet completed? I know that sites don't like to be "bugged", but if they understand that tracking reimbursement is LINKED to completion of that form, it may be better tolerated.

Reminders for missing forms can be posted to the web as they are for the other protocols, we don't email them out anymore, it's too time consuming. I'll add this to the list of special edit reports. Also, Jamie sent a reminder to all PIs/coordinators concerning the SEF01 and the tracking tools for 6-7 Year Follow-up on 08/25/2009

i. BTW, from the MasterMRIFU spreadsheet I think we have **68 or 69 subjects who have already have their window open for 3-4 year tracking! 9 or 10 patients will have that window CLOSED by the end of this month!** Are the tracking forms in on those yet?

I have an MR table that shows the numbers for this, I can attach the missing forms edit to it.

b. $$ for tracking between 18-22 months and 3-4 years: Rose, can you tell me how much was the FINAL budgeted for the contacts between 18-22 months and 3-4 years? We had said in the original budget that it would be 2 one-hour contacts at $35/hr, but I think that was revised upward. Also, from a process perspective, when are those funds released to sites? As soon as they complete the 3-4 year tracking form? Or when the patient will reach 3-4 years IF the tracking form has been completed?

c. How will the later tracking funds will be distributed and contact attempts "verified"? In the protocol, we originally budgeted four 2 hour tracking contacts (total 8 hours of tracking contact at $35/hr) for tracking between 3-4 years and the school age follow-up visit. We now have a mechanism in place to "track the tracking" at 3-4 years. But what should we do for tracking between 3-4 and the school age visit? Just a reminder email at 5 _ years? And are we just distributing the tracking funds without "verification"?

5) Data "cleaning" and analysis:

a. Qing - we could probably start talking about starting some data clean up and setting up analyses so we can be ahead of the game.

i. I have a few ideas for cleaning up the data. For instance, we will need to look at "normal" and make sure there really are NO things marked on the form or comments made. Also, we will need to search the comments for any mention of

cerebellar or cerebellum because some abnormalities in that area were not so easily categorized. Also a few other things, but I will make a list of things I am thinking about, and you can also tell me what you think.

Please make a list and send to Qing, she will look this over, add anything if needed, and you guys can get to work!

ii. As for how we will look at the data and prelim analysis - should I put together some mock data tables?

Sure, please. Mock tables do help get analysis organized. I will also look into the protocol to think about analyses. We will probably have many rounds to get the analysis finalized, so feel free to ask me anything that may come up. I am looking forward to it. -QY

Good Morning Rosemary,

I have changed the answer to the question on (b) (6) because the patient definitely was not 18 months old at the time of the exam. Sorry for the inconvenience.
Please let us know if you need us to correct anymore information. Thank you.

Respectfully,

Subject: RE: ROP documents

Neil,

As far as the primary outcome is concerned, in the data I sent a positive ROP outcome is defined as when both eyes meet the criteria of vessels in zone 4=Mature for one exam or in zone 3=III for two consecutive exams. A negative ROP outcome is defined as when one or both eyes has Threshold (New Type I) ROP as recorded on the SUPP10, has ROP stage 4 or 5, or has surgery for ROP.

The reason I sent such detailed data is that we need to review the exam data for inconsistencies or "red flags" that would cause us to doubt that the data are correct. For example, if one eye has lowest zone of any vessels of 4=Mature and the other eye has ROP stage 4, we would probably want to query that site to see if a typo had been made. As I look at the data I sent you all, I can see multiple instances where there are such inconsistencies that need to be cleared up. But, I am not an expert on ROP, so I know that I will not be able to identify all potential problems on my own. I will need other eyes to review the data so that we can put together queries to send the centers.

Thanks, everyone, for your help in this. I know it's a lot to look at, but it will help us ensure that our primary outcome data are as clean as possible.

Subject: RE: ROP documents

Hi Marie
We are looking at the crosstabs and will send a final answer in an hour or so. Overall we should resolve any discrepancies but for timing etc – unless the difference indicates that the intervention was done as per protocol or not, then such discrepancies are not worth resolving
The ROP data is obviously based on Dales very detailed input. However, lets look at how we are defining ROP – either threshold or surgery –
I assume that for any child, a single eye involvement is sufficient to meet this primary and concordance between the eyes is of interest but not for the primary.
The definition of the Threshold ROP is as follows:
Threshold (New Type I) ROP
Threshold (New Type I) ROP is defined as:
• In Zone II: plus disease with stage 2 or stage 3
• In Zone I: plus disease with any stage ROP, or stage 3 without plus disease
I can't see where it was said or not but are you working on the assumption that an infant has ROP if they meet the criteria or had surgery on any eye or are you looking at both eyes. For me, it would be any eye in a child that meets the definition of Threshold, whether the other eye meets this or not and the same for surgery.
Much of the data that you sending I believe is for more secondary outcomes to look at more detail than is needed or wanted for the Primary. Is this also your understanding of this issue?

Subject: ROP documents

Hi all,

Please find attached four ROP documents for your review (described below). Before we do the ROP analysis, we will need to clean the ROP data as we have been doing for BPD. This will likely involve sending out a batch of queries for the centers to resolve inconsistencies within and between forms. As I am less familiar with ROP than I am with the BPD outcomes, I will need your help to identify inconsistencies that need to be resolved. The attached documents were created in order to facilitate that process. Perhaps we can review them together during our meeting on Monday.

1) **SUPP10 ROP cross-tabs (all exams) 8-27-09.rtf** – This document contains cross-tabulations of ROP data for all exams entered on the SUPP10. The purpose of this document is to help identify any inconsistent data within the exams.
2) **Current and previous exam results by ROP reason 8-27-09.rtf** – For all infants with a final

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

ROP determination, selected data from the current exam (from which the ROP determination was made) and the previous exam for the infant are presented. Additional information included are the estimated PMA at the time of the current exam and the number of days between the current and previous exam. The purpose of this document is to help identify cases where the change in ROP data between exams seems unreasonable for the amount of time that elapsed between the exams.

3) **Cases where ROP status changed per SUPP10 8-27-09.rtf** – This document lists data from each ROP exam for infants whose final ROP status appears to have changed over time (final status was positive but changed to negative at a subsequent exam or vice versa). The purpose of this document is to determine whether or not the changes in status seem reasonable.
4) **ROP on NG03 vs SUPP10 8-27-09.rtf** – This document contains cross-tabulations of similar data fields on the NG03 and SUPP10. Note that only SUPP10 exams that occurred by the date of NG03 status are included in this comparison. Because ROP exam dates are not entered on the NG03, and it is therefore not clear precisely which exams were consulted when the NG03 data were entered, it may be difficult to compare the data on these two forms.

Neil and Wade, have you had a chance to look over the proposed cross-form queries I sent you on 8/18? As these queries involve many important data elements, including treatment variables like intubation/surfactant and outcomes like air leaks and IVH, we need to have these inconsistencies resolved before we finalize the SUPPORT manuscripts. If at all possible, I would like to send these queries to the centers by the end of next week. As I told everyone when we planned the analysis meeting, I will be out of town September 5-20, so it would be nice if the centers could be working on the queries during that time.

For the meeting on Monday, I will have my analysis datasets for BPD, ROP and other outcomes available for review. Please let me know if there is anything else of high-priority for me to prepare for Monday. Time is obviously limited, but I will try to accommodate.

I look forward to reviewing the SUPPORT data with you next week.

Thanks,
Marie

ABSTRACT

Background

The incidence of retinopathy increases with exposure to high levels of oxygenation in premature infants but the range of oxygen saturations that reduce adverse outcomes is not known.

Methods

We randomly assigned at birth 1310 infants of 24 to 27 weeks gestation to oxygen saturation targets of 85 to 89% or 91 to 95%. The primary outcome was a composite of threshold retinopathy of prematurity, eye surgery for retinopathy, and/or death.

Results

Conclusions

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

INTRODUCTION

Retinopathy of prematurity remains an important cause of blindness and other visual disabilities among prematurely born infants. The incidence of retinopathy of prematurity is increased with exposure to high levels of oxygenation in premature infants. Oxygen saturation levels previously thought to be in the upper limits of normal increase the risk of retinopathy of prematurity.[1, 2, 3] Oxygen toxicity may also increase the risk of mortality[4,5], bronchopulmonary dysplasia[6,7], and other morbidities. While data from prospective observational and retrospective studies suggest that maintenance of oxygenation at lower ranges may decrease the incidence of retinopathy of prematurity, there is no conclusive evidence regarding the oxygenation levels that reduce retinopathy of prematurity without an increase in adverse effects.

We conducted a 2 x 2 factorial-design multicenter randomized trial of oxygen saturation targeting, testing the effect of a lower oxygen saturation range (85-89%) as compared to a higher oxygen saturation range (91-95%) on the incidence of threshold retinopathy of prematurity and/or need for surgical eye intervention or death among infants of 24 to 27 weeks gestational age at birth. The factorial design allowed comparing prophylactic/early surfactant versus continuous positive airway pressure, thus, controlling for the approach to ventilatory support.

METHODS

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

The institutional review boards at all Neonatal Research Network clinical centers and Research Triangle International approved the trial. Written informed consent was obtained from the parent or guardian of each participant.

Patients

Infants of $24^{0/7}$ to $27^{6/7}$ weeks without a decision to forgo support were eligible for enrollment at birth. Exclusion criteria were outborn infants and major congenital anomalies. Multiples were randomized to the same arm of the trial.

Enrollment and treatment

Infants were stratified by gestational age ($24^{0/7}$ to $25^{6/7}$ weeks or $26^{0/7}$ to $27^{6/7}$ weeks) and by center. Infants were randomly assigned by means of double-sealed envelopes to oxygen saturation targeting of 85 to 89% or 91 to 95% with masking using electronically-altered pulse oximeters with output display of 88 to 92% for these oxygen ranges, an offset of 3% as previously used to separate oxygen saturations in premature infants.[8] They were also randomly assigned to respiratory support using either prophylactic/early surfactant with conventional ventilation management or continuous positive airway pressure with permissive ventilation management. The oxygen saturation values displayed reverted to actual values when less than 85% or greater than 95%. Saturation targeting was initiated immediately following admission and no later than two hours after admission. Oxygen saturation targeting with the altered pulse oximetry was continued as long as the infant remained on room air and off the ventilator/continuous positive airway pressure for 72 hours until 36 weeks post-menstrual age. Targeting of saturation was performed by the clinicians, not by the research staff.

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

Assessments

Research nurses recorded all data using standardized definitions. Threshold retinopathy of prematurity (New Type 1 threshold per Early Treatment of Retinopathy [ETROP] Cooperative Group[9]) was coded if any of the following four findings were present up to 52 weeks post-menstrual age:

If in Zone 1: Stage 3 retinopathy of prematurity, even without plus disease
Plus disease with any stage retinopathy of prematurity

If in Zone II: Plus disease with stage 2 retinopathy of prematurity
Plus disease with stage 3 retinopathy of prematurity

Surgical intervention included laser therapy, cryotherapy, laser/cryotherapy, scleral buckle, and vitrectomy. Death was coded up to 36 weeks post-menstrual age. Secondary outcomes included each of the individual outcomes above and predefined clinical diagnoses and potential adverse events.

Statistical analysis

The primary analysis of this factorial trial was a logistic regression analysis of the percentages of infants in each group (lower versus higher oxygen saturations) who developed the primary outcome. An absolute difference of 10% between the two treatment groups was considered clinically important. To detect the difference, we planned to enroll 1310 infants for 80% power and a baseline rate of 45% of death/threshold retinopathy/surgery. Intention-to-treat analyses were performed. The denominator used to calculate the rate of each outcome was the number of infants for whom that outcome was known. Analyses were conducted by the staff at the data center. A two-sided P value of less than 0.05 was considered to statistically significant. Analyses did not include adjustment for

multiple comparisons. An independent data safety monitoring committee reviewed the interim results, including those concerning adverse outcomes, four times. Pocock boundaries were used to develop stopping rules for interim safety monitoring.

Hi Marie
Thanks for going over these Tables with me. Marie and I reviewed the discrepancies that she identified and we defined situations where a further query would be appropriate. We also reviewed the Table: Cases where ROP status changed and reviewed each one of these. Marie will query those cases that we identified.
I suggested the following as grounds for asking for further information
1. Any case where the individual eyes differed by more than 2 stages/grades
2. Any case where the ROP was diagnosed as Stage 4 or 5 with NO antecedent stages or threshold or surgery
3. Any case where the surgery was only performed in 1 eye. The usual experience is that such discrepancies occur in 10% or less of cases and Marie thinks that overall we have about 120 cases.
I hope this helps.
Thanks again Marie
Neil

Subject: RE: ROP documents

Neil,

As far as the primary outcome is concerned, in the data I sent a positive ROP outcome is defined as when both eyes meet the criteria of vessels in zone 4=Mature for one exam or in zone 3=III for two consecutive exams. A negative ROP outcome is defined as when one or both eyes has Threshold (New Type I) ROP as recorded on the SUPP10, has ROP stage 4 or 5, or has surgery for ROP.

The reason I sent such detailed data is that we need to review the exam data for inconsistencies or "red flags" that would cause us to doubt that the data are correct. For example, if one eye has lowest zone of any vessels of 4=Mature and the other eye has ROP stage 4, we would probably want to query that site to see if a typo had been made. As I look at the data I sent you all, I can see multiple instances where there are such inconsistencies that need to be cleared up. But, I am not an expert on ROP, so I know that I will not be able to identify all potential problems on my own. I will need other eyes to review the data so that we can put together queries to send the centers.

Thanks, everyone, for your help in this. I know it's a lot to look at, but it will help us ensure that our primary outcome data are as clean as possible.

Marie

Subject: RE: ROP documents

Hi Marie
We are looking at the crosstabs and will send a final answer in an hour or so. Overall we should resolve any discrepancies but for timing etc – unless the difference indicates that the intervention was done as per protocol or not, then such discrepancies are not worth resolving
The ROP data is obviously based on Dales very detailed input. However, lets look at how we are defining ROP – either threshold or surgery –
I assume that for any child, a single eye involvement is sufficient to meet this primary and concordance between the eyes is of interest but not for the primary.
The definition of the Threshold ROP is as follows:
Threshold (New Type I) ROP
Threshold (New Type I) ROP is defined as:
• In Zone II: plus disease with stage 2 or stage 3
• In Zone I: plus disease with any stage ROP, or stage 3 without plus disease
I can't see where it was said or not but are you working on the assumption that an infant has ROP if they meet the criteria or had surgery on any eye or are you looking at both eyes. For me, it would be any eye in a child that meets the definition of Threshold, whether the other eye meets this or not and the same for surgery.
Much of the data that you sending I believe is for more secondary outcomes to look at more detail than is needed or wanted for the Primary. Is this also your understanding of this issue?
Neil

Subject: ROP documents

Hi all,

Please find attached four ROP documents for your review (described below). Before we do the ROP analysis, we will need to clean the ROP data as we have been doing for BPD. This will likely involve sending out a batch of queries for the centers to resolve inconsistencies within and between forms. As I am less familiar with ROP than I am with the BPD outcomes, I will need your help to identify

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

inconsistencies that need to be resolved. The attached documents were created in order to facilitate that process. Perhaps we can review them together during our meeting on Monday.

1) **SUPP10 ROP cross-tabs (all exams) 8-27-09.rtf** – This document contains cross-tabulations of ROP data for all exams entered on the SUPP10. The purpose of this document is to help identify any inconsistent data within the exams.
2) **Current and previous exam results by ROP reason 8-27-09.rtf** – For all infants with a final ROP determination, selected data from the current exam (from which the ROP determination was made) and the previous exam for the infant are presented. Additional information included are the estimated PMA at the time of the current exam and the number of days between the current and previous exam. The purpose of this document is to help identify cases where the change in ROP data between exams seems unreasonable for the amount of time that elapsed between the exams.
3) **Cases where ROP status changed per SUPP10 8-27-09.rtf** – This document lists data from each ROP exam for infants whose final ROP status appears to have changed over time (final status was positive but changed to negative at a subsequent exam or vice versa). The purpose of this document is to determine whether or not the changes in status seem reasonable.
4) **ROP on NG03 vs SUPP10 8-27-09.rtf** – This document contains cross-tabulations of similar data fields on the NG03 and SUPP10. Note that only SUPP10 exams that occurred by the date of NG03 status are included in this comparison. Because ROP exam dates are not entered on the NG03, and it is therefore not clear precisely which exams were consulted when the NG03 data were entered, it may be difficult to compare the data on these two forms.

Neil and Wade, have you had a chance to look over the proposed cross-form queries I sent you on 8/18? As these queries involve many important data elements, including treatment variables like intubation/surfactant and outcomes like air leaks and IVH, we need to have these inconsistencies resolved before we finalize the SUPPORT manuscripts. If at all possible, I would like to send these queries to the centers by the end of next week. As I told everyone when we planned the analysis meeting, I will be out of town September 5-20, so it would be nice if the centers could be working on the queries during that time.

For the meeting on Monday, I will have my analysis datasets for BPD, ROP and other outcomes available for review. Please let me know if there is anything else of high-priority for me to prepare for Monday. Time is obviously limited, but I will try to accommodate.

I look forward to reviewing the SUPPORT data with you next week.

Thanks,
Marie

HI Wally
I am OK with this but I do not want us to get bogged down in what appears to be a lot of data for a secondary regarding detailed yery diagnoses and concordance. We need to focus on the occurrence of the primary outcome and spend time looking at such data that is unclear. The ability to make the diagnosis of ROP should be reasonably transparent, albeit there will be infants without the exam at the time etc.
Rose can we see if Dale is available for an hour on Monday afternoon so that we could engage her in such a discussion?
Thanks
Neil

Thanks, Marie.

In contrast to Marie, I am really unfamiliar with all the details of the ROP diagnosis. Rose is an expert on ROP. I think we need to plan to be able to consult Dale. Maybe we should check out availability for a conf call with Dale while we are in DC on Monday (just in case it is needed).

The attached documents were created in order to facilitate that process. Perhaps we can review them together during our meeting on Monday.

1) **SUPP10 ROP cross-tabs (all exams) 8-27-09.rtf** – This document contains cross-tabulations of ROP data for all exams entered on the SUPP10. The purpose of this document is to help identify any inconsistent data within the exams.
2) **Current and previous exam results by ROP reason 8-27-09.rtf** – For all infants with a final ROP determination, selected data from the current exam (from which the ROP determination was made) and the previous exam for the infant are presented. Additional information included

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

are the estimated PMA at the time of the current exam and the number of days between the current and previous exam. The purpose of this document is to help identify cases where the change in ROP data between exams seems unreasonable for the amount of time that elapsed between the exams.

3) **Cases where ROP status changed per SUPP10 8-27-09.rtf** – This document lists data from each ROP exam for infants whose final ROP status appears to have changed over time (final status was positive but changed to negative at a subsequent exam or vice versa). The purpose of this document is to determine whether or not the changes in status seem reasonable.
4) **ROP on NG03 vs SUPP10 8-27-09.rtf** – This document contains cross-tabulations of similar data fields on the NG03 and SUPP10. Note that only SUPP10 exams that occurred by the date of NG03 status are included in this comparison. Because ROP exam dates are not entered on the NG03, and it is therefore not clear precisely which exams were consulted when the NG03 data were entered, it may be difficult to compare the data on these two forms.

Neil and Wade, have you had a chance to look over the proposed cross-form queries I sent you on 8/18? As these queries involve many important data elements, including treatment variables like intubation/surfactant and outcomes like air leaks and IVH, we need to have these inconsistencies resolved before we finalize the SUPPORT manuscripts. If at all possible, I would like to send these queries to the centers by the end of next week. As I told everyone when we planned the analysis meeting, I will be out of town September 5-20, so it would be nice if the centers could be working on the queries during that time.

For the meeting on Monday, I will have my analysis datasets for BPD, ROP and other outcomes available for review. Please let me know if there is anything else of high-priority for me to prepare for Monday. Time is obviously limited, but I will try to accommodate.

I look forward to reviewing the SUPPORT data with you next week.

Thanks,
Marie

Attachments:	SUPP10 ROP cross-tabs (all exams) 8-27-09.rtf Current and previous exam results by ROP reason 8-27-09.rtf Cases where ROP status changed per SUPP10 8-27-09.rtf ROP on NG03 vs SUPP10 8-27-09.rtf

Hi all,

Please find attached four ROP documents for your review (described below). Before we do the ROP analysis, we will need to clean the ROP data as we have been doing for BPD. This will likely involve sending out a batch of queries for the centers to resolve inconsistencies within and between forms. As I am less familiar with ROP than I am with the BPD outcomes, I will need your help to identify inconsistencies that need to be resolved. The attached documents were created in order to facilitate that process. Perhaps we can review them together during our meeting on Monday.

1) **SUPP10 ROP cross-tabs (all exams) 8-27-09.rtf** – This document contains cross-tabulations of ROP data for all exams entered on the SUPP10. The purpose of this document is to help identify any inconsistent data within the exams.
2) **Current and previous exam results by ROP reason 8-27-09.rtf** – For all infants with a final ROP determination, selected data from the current exam (from which the ROP determination was made) and the previous exam for the infant are presented. Additional information included are the estimated PMA at the time of the current exam and the number of days between the current and previous exam. The purpose of this document is to help identify cases where the change in ROP data between exams seems unreasonable for the amount of time that elapsed between the exams.
3) **Cases where ROP status changed per SUPP10 8-27-09.rtf** – This document lists data from each ROP exam for infants whose final ROP status appears to have changed over time (final status was positive but changed to negative at a subsequent exam or vice versa). The purpose of this document is to determine whether or not the changes in status seem reasonable.
4) **ROP on NG03 vs SUPP10 8-27-09.rtf** – This document contains cross-tabulations of similar data fields on the NG03 and SUPP10. Note that only SUPP10 exams that occurred by the date of NG03 status are included in this comparison. Because ROP exam dates are not entered on the NG03, and it is therefore not clear precisely which exams were consulted when the NG03 data were entered, it may be difficult to compare the data on these two forms.

Neil and Wade, have you had a chance to look over the proposed cross-form queries I sent you on 8/18? As these queries involve many important data elements, including treatment variables like intubation/surfactant and outcomes like air leaks and IVH, we need to have these inconsistencies resolved before we finalize the SUPPORT manuscripts. If at all possible, I would like to send these queries to the centers by the end of next week. As I told everyone when we planned the analysis meeting, I will be out of town September 5-20, so it would be nice if the centers could be working on the queries during that time.

For the meeting on Monday, I will have my analysis datasets for BPD, ROP and other outcomes available for review. Please let me know if there is anything else of high-priority for me to prepare for Monday. Time is obviously limited, but I will try to accommodate.

I look forward to reviewing the SUPPORT data with you next week.

Thanks,
Marie

The other more practical concern is that we would miss your expertise in ROP when reviewing the charts.

Thanks

Abhik

Abhik, Carolyn and Kris-
(b) (6) [redacted]

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

(b) (6) may not be able to attend the Duke site visit.

I am confident that RTI can obtain the appropriate information. I can get a "report" from you (based on the agenda that Kris already put together) and then formulate recommendations as needed. I think there is urgency to do this next week to sort out the SUPPORT ROP data.

Would this be ok for you to go without me?

Let me know

Thanks
Rose

Rose,
I think we have satisfied all the BPD questions except for 3 charts (have been requested and should have this week). I am in the process of reviewing to make sure that all PH01's that should be entered, have been entered and not just coded on the NG07. Do not have any new nesws on the ROP front. Will keep working on it.
Ellen

Hi,

Can you let us know if you have made progress? We are anxious to have all queries resolved to move on with the analysis!!
Thanks

Hi,

We are getting close to having final outcomes for SUPPORT. Thanks for all your hard work. I have attached the BPD queries and an explanation for the queries to the email. In addition, we are missing the following primary outcomes for SUPPORT listed below.

Again, thanks so much for all the hard work and effort!!
Regards,

Rose

I agree Wally
I am asking are we powered for this outcome – This strata is bigger than almost any previous trial. That is my question to Abhik.

NEJM has published specific requirements necessary for reporting subgroups results. Only if we meet those criteria, should we include it in the paper. As we did not pre-specify the subgroup analysis and are not powered for it, we need to be very thoughtful on whether we should report it of highlight it.

I may have missed it, but I don't see any explicit mention in the protocol of our intent to report outcomes by GA strata. So, I would say that while we can certainly report this and comment on it, we are perhaps better off not playing it up too much, beyond saying that it is a strongly suggestive result. NEJM would also likely not allow us to include it in the abstract.

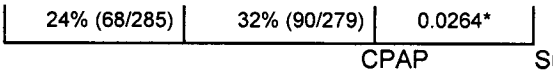
Hello Everyone
It appears we can find whatever definition we want.
The problem using the Physiologic as the primary is that we did not use Physiologic BPD to determine the sample size or postulated improvement. The protocol is obviously unclear. I would suggest that we report both but that we stick to BPD defined as Oxygen at 36 weeks as the primary as this is the only way to allow others to interpret our data and guys like me who do the meta analyses to combine trials.
There was simply too much interpretation required for the Physiologic and no agreed to standards as to how one would define an individual child – ie on NC at 1 lpm RA ? BPD or NO? NC at 2 LPM BPD or NO?. Nasal CPAP RA – BPD or NO?
No other study has done the oxygen withdrawal in other prospective trials. While the Physiologic will no doubt provide some useful info – I would not want this trial to depend on it. I am also unsure how you power a study using one outcome and then use that data to measure the effect of another.

The other major result – and we have significance without manipulation – is the death rate in the small strata.
This is a major difference and larger than any BPD outcome. This strata is larger than any trial of this population for respiratory interventions. Abhik What will be allowed to say?? 24-25 weeks strata



Neil

This is also from the current protocol (page 21)

5.3.1 Primary Outcome Measure

The primary outcome will be the percentage of infants surviving without BPD (using the Physiologic Definition) or severe ROP (threshold disease or the need for surgery).

The protocol states:

2.2 Primary Hypotheses

1). We hypothesize that relative to infants managed with prophylactic/early surfactant and conventional ventilation that the use of early CPAP and a permissive ventilatory strategy in
infants of less than 28 weeks gestation with continuing CPAP in the NICU will result in an increased survival without BPD at 36 weeks.

In the protocol physio def is listed as a predefined secondary outcome

Neil:

I just checked the protocol. The primary outcome was death/BPD (with phys def). There is a secondary also for BPD by phys def. I think it would be best to report this as well as BPD by clinical needs as well as other measures of O2 or vent needs. All of this could be the part of the main analysis.

All – A reminder for our call today. Please see updated agenda below and attached materials.

UPDATED: Steering Committee Conference Call Agenda 08/25/2009

1. Hydrocortisone protocol presentation (3-3:40) – Presentation and protocol attached
2. SUPPORT Update – Dr. Finer – materials attached (confidential)
3. Vitamin E Update
4. NEST Update
5. FU Bayley III motor component
6. New business

Hello Everyone
I am delighted to send you the first look at the SUPPORT Results with thanks to Marie and Abhik.
Please find the basic demographic tables and the outcome of BPD and death etc. You will note that Death/BPD using the need for oxygen at 36 weeks as the postulated primary – because that was the data we based the study on – is significant both unadjusted and adjusted. Note that BPD is also less for the Low SpO2 group – but for that study, we need ROP which we are still waiting for.
Congratulations on a study well done to you all and the coordinators, and RTI
Wally Wade and I will be at RTI a week today to review all the data and I have already started the first paper.
Be well
Neil

Subject: SUPPORT MRI project
Date: Tuesday, August 25, 2009 12:27:08 PM

Hi Pat

I know you have been going crazy with all the NICHD projects and everything else in your life and work. I realize the Hypothermia MRI project was much more involved and complex than originally planned. I also realize that there have been suggestions made on the hypothermia conference calls about further "re-readings" and proceeding with intrarater reliability reads at this point. I think the results of the hypothermia MRI project will be truly interesting and important, and I am excited to see the final findings. However, as you know, the SUPPORT (premie) MRI project has been completely on hold for many months now, and we must move forward. I know you have been put in the middle of all this, and you also have many other demands on your time. I have spoken with Rose Higgins, and she agrees that it is time to let you truly and completely set aside the hypothermia project and move full steam forward on SUPPORT. So, after the Friday hypothermia conference call (which hopefully will wrap up the final questions about the readings), you will not be dealing with hypothermia at all in the near future. It may be that at some point (after all is complete with SUPPORT), you may be engaged to do re-reads, but not until SUPPORT is complete.

The SUPPORT MRI reading is critical at this point, because all of the CUS central reads are just about completed. The main trial results (i.e., whether the ventilation and oxygenation target interventions impacted the rates of BPD and other short term outcomes) will be coming out very soon - and they are likely to be very interesting and high profile. So, it is crucial that we get these important secondary analyses out and in the public eye as soon as possible.

I would envision the first abstract from the neuroimaging component of SUPPORT to be broad in scope - just a report of brain injuries on CUS and MRI, perhaps very preliminary comparison of late CUS and MRI in terms of findings. We do not yet have neurodevelopmental follow-up data at 18-22 months, so that will be an analysis for later. In order to make the deadline for the Pediatric Academic Societies meeting late breaker abstract (which would be a high-impact meeting in which to present the report, and would also be the same meeting as the main trial results are reported), realistically all SUPPORT neuroimaging needs to be read by beginning of November. That is even pushing it, and assumes that I will be sending back the readings as they are done, dealing with data entry questions in "real time" and setting up preliminary analysis plans in the next month or so with statisticians. This will mean you would need to read ~50-55 MRIs each week. I will commit to set aside as much time in my schedule whenever you want me to help (i.e., early mornings, evenings, etc) to help score and get this done. Is this possible?

Please let me know what you think - thanks Pat

Subject: Data requests, tracking, etc re: SUPPORT neuroimaging
Date: Tuesday, August 25, 2009 1:35:34 AM
Attachments: MasterMRIFU_20090610.xls

Hi Meg, Qing, Jenny, Jamie, Rose, Abhik,

With the second central US reading for SUPPORT just completed, we now need to tackle the issue of what we have completed, what we have left to do, what is missing, etc. We need this to plan how the rest of the CUS readings will be done, the timeline, and analysis plans. **I would like for us to have something completed for late breakers PAS - and I think realistically we need to say all readings must be done and input by beginning of November, providing we have been inputting the central reader data as it comes in.** (And also provided we start data cleaning and plan for analysis strategy.)

In addition, thinking about how we will wrap up the neuroimaging readings and analysis has reminded me to ask a separate series of questions about the 18-22 mo follow-up and school-age follow-up.

So here it goes -

1) Characterization of CUS studies: expected, done, left to do, plans for remaining reading.

a. In order to plan how many days we need to read with Dr. Bulas and Dr. Slovis, we will need the following info:

i. How many total CUS are expected in the entire study? (All MRI01 forms should be submitted by now, so we should know this number at this point.)

ii. Are any of these "expected" CUS still not sent to RTI by the sites?

iii. How many CUS were read in the first central reading by DB, how many by TS?

iv. How many total CUS were read in the second central reading by DB, how many by TS?

v. How many patients have BOTH early and late CUS? How many of these have been completely read by both DB and TS?

vi. How many have COMPLETE neuroimaging (early CUS, late CUS, MRI)

b. Of course we want every CUS we can get, but the most important group for the study as a whole is the group that has all neuroimaging. So, we should be most aggressive about getting the CUS that are missing in that group.

2) Setting up more readings

a. As we discussed at the central reading, we should **move forward now with arranging separate dates for RTI to go out to Dr. Slovis and Dr. Bulas to finish up** the readings- and I think Meg may already be looking at dates for her and Amanda to vist with Dr. Bulas. I believe Julie will be going out to see Dr. Slovis? In any case, I

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

recommend nailing down a FEW DATES NOW for the next 4 -6 weeks (even if it is a day here and a day there).

3) More data requests, but related to above questions:

a. The big spreadsheet Meg has and I want: Meg has a very nice spreadsheet with what I believe is ALL patients who were enrolled in SUPPORT Neuroimaging who have ANY CUS. Could I have an updated version of that electronically?

i. Will the "updated version" I receive be final and complete? In other words, will all the MRI01 data be in by now.

ii. Also, that spreadsheet indicates if Early or Late US and MRI were doneŠbut not whether they have been received. I really don't want to make that spreadsheet more cumbersome, so don't add columns, you can just answer 1.b above.

b. "MasterMRIFU" data sheet: Jenny Auman made a really nice spreadsheet for me with all sorts of information pertinent to the neuroimaging and follow-up issues. Jenny - could I have an updated version? **I am attaching the June 10 version just to show you which spreadsheet I mean.**

c. Pertinent to questions 1.f - looking at the June 10 version of the MasterMRIFU list, it seems that there are only 12 patients with an early CUS and a successful MRI, but NO late CUSŠthis is a group (and of course there may be more than 12 now) that we should really try to understand. As I said above, the most important group we should focus on is the group that have ALL neuroimaging, so if they are missing a late CUS but they actually have one somewhere, we should try to snag it.

4) Tracking for extended follow-up - I know a lot of questions will come up about the details of this and the $$ involved as we move toward the follow-up of this group. So here are a few questions and comments -

a. REMINDERS to sites? As you know, we did remind PI's about the 3-4 year tracking for the school age follow-up on the FU PI conference call. However, can we do something more formal - or are you already doing that? Can you - or are you already planning to - send out an email 3 months before the 3-4 year window opens to remind about the form, then again at 3 _ years IF the form is not yet completed? I know that sites don't like to be "bugged", but if they understand that tracking reimbursement is LINKED to completion of that form, it may be better tolerated.

i. BTW, from the MasterMRIFU spreadsheet I think we have **68 or 69 subjects who have already have their window open for 3-4 year tracking! 9 or 10 patients will have that window CLOSED by the end of this month!** Are the tracking forms in on those yet?

b. $$ for tracking between 18-22 months and 3-4 years: Rose, can you tell me how much was the FINAL budgeted for the contacts between 18-22 months and 3-4 years? We had said in the original budget that it would be 2 one-hour contacts at $35/hr, but I think that was revised upward. Also, from a process perspective, when are those funds released to sites? As soon as they complete the 3-4 year tracking form? Or when the patient will reach 3-4 years IF the tracking form has been completed?

c. How will the later tracking funds will be distributed and contact attempts "verified"? In the protocol, we originally budgeted four 2 hour tracking contacts (total 8 hours of

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

tracking contact at $35/hr) for tracking between 3-4 years and the school age follow-up visit. We now have a mechanism in place to "track the tracking" at 3-4 years. But what should we do for tracking between 3-4 and the school age visit? Just a reminder email at 5 _ years? And are we just distributing the tracking funds without "verification"?

5) Data "cleaning" and analysis:

a. Qing - we could probably start talking about starting some data clean up and setting up analyses so we can be ahead of the game.

i. I have a few ideas for cleaning up the data. For instance, we will need to look at "normal" and make sure there really are NO things marked on the form or comments made. Also, we will need to search the comments for any mention of cerebellar or cerebellum because some abnormalities in that area were not so easily categorized. Also a few other things, but I will make a list of things I am thinking about, and you can also tell me what you think.

ii. As for how we will look at the data and prelim analysis - should I put together some mock data tables?

Thanks again all! I am sure I have forgotten a lot, but that's it for now.

THANKS for all your help and great work!

Susan

Hi Wally
We only had 2 primaries – Death/BPD at 36 wks and NDI
We can certainly look at these but I doubt that we could say much in NEJM – Lets discuss this. I also want to see the interaction between Low SpO2 ands CPAP
We have a lot of work to do together!!
Be well

Neil:

Great job to you and all.

I think a very important outcome is severity of BPD as measured by duration of ventilatory support and of O2 supplementation as well as on a vent at 36 weeks. I think these were pre-specified.

I would like to make sure we look at these.

Hello Everyone
I am delighted to send you the first look at the SUPPORT Results with thanks to Marie and Abhik. Please find the basic demographic tables and the outcome of BPD and death etc. You will note that Death/BPD using the need for oxygen at 36 weeks as the postulated primary – because that was the data we based the study on – is significant both unadjusted and adjusted. Note that BPD is also less for the Low SpO2 group – but for that study, we need ROP which we are still waiting for.

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

Congratulations on a study well done to you all and the coordinators, and RTI
Wally Wade and I will be at RTI a week today to review all the data and I have already started the first paper.
Be well
Neil

Hi Ivan
The protocol may say this but my understanding was always that our postulate was based on existing Network outcomes of BPD that were NOT based on the physiologic definition, and that was how we calculated the power of the study. I do not believe the Network had or used such data for the calculations for the SUPPORT trial.
In addition the physiologic requires many interpretations of infants who were or were not challenged, not all were!, requires assumptions of BPD based on nasal cannula flow or other treatments and use of these does not allow comparison of our data with any other study.
I have always assumed that we would use the conventional definition and look at the physiologic and see how clear this is. The previous assumption was that the Physiologic Definition would lower the actual BPD rate and we did not postulate that. Indeed as can be seen, the Physiologic definition resulted in very similar estimates
Our results show almost the same absolute decrease in death or BPD as the COIN trial comparing CPAP to the Controls using the same definitions – 6% for our study, 5% for COIN.
We will need further dialogue about this
Thanks
Neil

Neil: Congratulations on pulling all this together so quickly. The data are very interesting. A comment re the abstract: The end point you report, death or BPD defined as oxygen use at 36 weeks is not the primary endpoint as written in the protocol (death or BPD by physiologic definition). The data table indicates a discrepancy between these two endpoints. We need some thought and discussion as to how to move forward with this. I look forward to hearing more this afternoon.

Ivan

Subject: Steering Committee Call Tuesday

Dear All -

The next standing Steering Committee call is scheduled for Tuesday, August 25th at 3 PM ET.

Please Dial:
Outside the USA 1-203-310(b) (6)
or Within the USA 866-675-(b) (6)
Then, enter Participant Passcode: (b) (6)

Steering Committee Conference Call Agenda 08/25/2009

7. Hydrocortisone protocol presentation (3-3:40)
8. New business

Thanks!
Meg

The Surfactant Positive Airway Pressure and Pulse Oximetry Trial in Extremely Low Birth Weight Infants – The SUPPORT Trial

The SUPPORT Study Group of the Eunice Kennedy Shriver NICHD Neonatal Research Network

Abstract

Background: The most appropriate initial and ongoing respiratory support for the extremely low birthweight infant (ELBW) has not been established by adequate prospective evidence. The current usual approaches include the early use of continuous positive airway pressure (CPAP) or the early administration of surfactant following endotracheal intubation. No study to date has compared these approaches in a large population of ELBW infants

Methods: The SUPPORT study was a randomized multicenter trial that enrolled consented preterm infants of 24 0/7ths weeks to 27 6/7ths weeks by best obstetrical within 2 prospective strata, 24 to 25 6/7ths weeks, and 26 to 27 6/7th weeks. Infants randomized to CPAP were treated with CPAP initiated in the delivery room and continued following admission to the NICU and such infants could be intubated if they met prespecified criteria including an FiO2 >.50 required to maintain an indicated SpO2 > 88% for one hour, an arterial PaCO2 > 65 torr , and/or hemodynamic instability defined as a low blood pressure for gestational age and/or poor perfusion, requiring volume and/or pressor support for a period of 4 hours or more. Infants randomized to surfactant were intubated and received surfactant within 60 min minutes of birth. Criteria for extubation differed between the 2 groups with the CPAP infants treated using a permissive strategy allowing higher PaCO2s and extubation at higher ventilator settings. All infants were also randomized to one of 2 ranges of SpO2 while in the NICU and receiving supplemental oxygen, a low target range of 85% to 89% and a high target range of 91% to 95% using specifically altered blinded oximeters.

Results: The study enrolled 1316 infants from February 2005 to February 2009. There were 565 infants enrolled in the lower gestational age strata, and 751 in the higher strata. There were no significant differences for sex, birth weight, APGAR scores or race between the 2 groups. There were no differences between the groups in the receipt of

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

any or a full course of antenatal steroids, or compressions in the DR, whereas the Surfactant group received significantly more epinephrine in the delivery room (4% vs 2%, p=0.022). In the delivery room, 66% of the CPAP infants received positive pressure ventilation compared with 93% of the surfactant infants, and surfactant was given to 14% of the CPAP versus 51% of the surfactant group, and 67% of the CPAP infants received surfactant at any time during their hospitalization, (all p<0.001). There were no differences overall for death in the delivery room or death during the hospitalization, nor any differences in length of stay, or days of oxygen for survivors, and the need for oxygen at discharge. More CPAP infants were alive and off mechanical ventilation by day 7, (p=0.015). There were no differences between the groups for airleaks including penumothoraces, and no differences for medical or surgical NEC, PDA requiring surgery, or severe IVH. All infants in the Surfactant arm were intubated, compared with only 77% of the CPAP infants required intubation during their nursery course, (p<0.001). There was a significant reduction in the use of postnatal steroids for BPD in the CPAP infants compared with the Surfactant infants , 7% vs 13%, p=0.0004). The primary outcome of death or BPD, defined as the need for supplemental oxygen at 36 weeks post conceptional age was 48% versus 54%, (p = 0.035, p= 0.042 when adjusted for gestational age, center and familial clustering). There was a significantly higher mortality (32% vs 24%, p=0.026) in the 24 to 25 weeks strata for the infants in the Surfactant arm.

Conclusions: The use of early CPAP with a permissive ventilator strategy results in a decrease in death or survival with BPD defined as the need for oxygen at 36 weeks post conceptional age compared with the use of surfactant within 1 hour of birth and a conventional mechanical ventilation approach. There were no increased adverse outcomes in the CPAP group, and the surviving infants will be followed for a complete neurodevelopmental assessment at 18 to 22 months. Early CPAP and the use of a permissive ventilator strategy is an evidence based approach for the initial respiratory support of the ELBW infant.

Hello Everyone
I am delighted to send you the first look at the SUPPORT Results with thanks to Marie and Abhik.
Please find the basic demographic tables and the outcome of BPD and death etc. You will note that Death/BPD using the need for oxygen at 36 weeks as the postulated primary – because that was the data we based the study on – is significant both unadjusted and adjusted. Note that BPD is also less for the Low SpO2 group – but for that study, we need ROP which we are still waiting for.
Congratulations on a study well done to you all and the coordinators, and RTI
Wally Wade and I will be at RTI a week today to review all the data and I have already started the first paper.
Be well
Neil

Hi,
We are getting close to having final outcomes for SUPPORT. Thanks for all your hard work. I have attached the BPD queries and an explanation for the queries to the email. In addition, we are missing the following primary outcomes for SUPPORT listed below.

Again, thanks so much for all the hard work and effort!!
Regards,
Rose

Subject: Re: SUPPORT HEAD US"s
Date: Wednesday, August 19, 2009 3:58:48 PM

Rose,
I have complete HUS CD's for 37 study patients. The Parkland radiology department has been unable to locate 9 HUS's from 7 patients. We have written radiology reports from the missing HUS's and are attempting to locate those HUS's. We are also missing two MRI's at Children's MC which we are attempting to locate.
I will be sending the completed HUS's tonight and Meg should receive them tomorrow morning.
Thank you,
Nancy

Subject: RE: Support BPD queries

Hi Leslie,

Kris, Abhik and I had a conversation regarding the fact that Indiana uses the pregnancy wheel to calculate GA instead of using the GA at birth entered on the NG02. For purposes of SUPPORT, it is very important that we have the BPD outcome collected on all patients in a consistent manner, and since the outcome is assessed at 36 weeks PMA, we need that date to be calculated in a consistent manner (across the network) as well. So, I hate to ask you to do this, but we think it's important for the Indiana babies to have 36 weeks PMA calculated based on the NG02 GA in order to be consistent with the rest of the network, and for BPD-related data on NG07, PHY01, etc., to match that date. Please let us know if you have any questions, and also please let us know when you think you'll be able to make any necessary edits. As you know, we are working on finalizing the BPD data with the goal of having the paper submitted by the end of the year. Thanks so much for your help. We really appreciate all your hard work.

Subject: RE: true "drop dead" date for SUPPORT MRI reading?
Date: Wednesday, August 19, 2009 12:14:33 PM

Susan:

I discussed this issue with Jenny Auman, our lead programmer. As you know, for the Hypothermia MRIs, this process took a long time. There were errors in the forms Dr. Barnes completed, and we had to make numerous changes to the forms and system to accommodate them.

Assuming this is about 500 MRIs, that you can help Dr. Barnes complete the forms as they are currently set up, and that you can look them over prior to shipping to RTI, so that errors are minimized, we think we could have the data keyed in our system, cleaned and ready for analysis, in a month. But we need to take into account that this time would be the beginning of the holiday season, so we may need to add 2 more weeks for staff out on holidays. Another 2-3 weeks would likely be needed by Qing to get some very preliminary analyses done; so we are likely talking about a lead time of around 2 months. This would of course also depend on how many forms need to be keyed for preliminary analysis -- all that you send us or only a certain number of them?

Bottom line, my thinking is that while we can shoot for a PAS late breaker, the timeline would be tight, and it is more important to have the data correct and cleaned, and the analysis done right.

Thanks

Abhik

Subject: true "drop dead" date for SUPPORT MRI reading?

Hi folks,

As you know, Dr. Barnes has spent and continued to spend more time than anticipated on the Hypothermia MRI project, thus making his available time for the SUPPORT MRI project extremely reduced. (He has also had a few more drains on his time that were not anticipated that are clinically and otherwise related, so it's not just the hypothermia project alone that is causing problems - don't get me wrong.) However, I am going to try to make a case to shift attention back to reading SUPPORT MRI's because I think it will be important to have at least some preliminary information to report in time for a late breakers PAS abstract. This brings me to my central question for you - if the late breakers abstract is due mid-February (submission starts 1/24 for late breakers abstracts), what would the "drop dead" date be for Dr. Barnes to finish SUPPORT MRI reading? In

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

my dreams, I am thinking that if he were to start back on focused SUPPORT ASAP, read like a madman, with me cutting out as much time as possible to help him, and if I were to send in the completed forms to RTI as they are finished for data entry, it may be possible to get through SUPPORT MRI's by mid- to end or November. Would that leave enough time to look at some preliminary analyses (i.e., broad strokes about extent of white matter injury, gray matter injury, cortical and white matter maturation levels, basically stuff straight off the central reader form)?

Let me know what you think -

Thanks

Susan

Hi Rose,

We are almost done resolving these queries and will forward the corrections by this Thursday.

As for ROP outcomes, we have not 'Lost' these families but it has been difficult to make some contacts. For most there is no evidence of acute study outcome reached by 55 weeks PMA, so on the SUPP10 we will code that acute 55 week PMA outcome as 'Lost' because it is not known. We will continue to try making contacts and will look forward to coding the SUPP10 18 month column when we schedule/see the kids at Follow-up.

Thanks,
Becky

Hi Rose,

Please see below for all follow-up visit update information highlighted in bold and in blue/red. We will keep you updated as soon as any new information becomes available. We know this is time sensitive issue and we are working hard to have all data collected before the count down.

Thanks,

Gloria

Hi,
We are getting down to the wire for SUPPORT and are missing a few outcomes.
Please let us know how you are doing.

Thanks for all the effort!!
Rose

SUPPORT infants with missing ROP 08-14-09.rtf

Rose and Neil,

Attached is the list of infants who are missing primary outcome data this week and a summary of where we stand with the ROP outcome. For the BPD queries that Rose sent out, we have received responses from 8 centers that have completed the queries and I talked with another two centers today who are working on theirs. I have been working on some cross-form queries for other data items, such as IVH, and those will be ready to go out next week. Rose, do you want to send them or do you want RTI to send them? I hope to complete preliminary versions of the tables we discussed on the analysis call next week as well.

Have a good weekend.

Marie

Rose,

We have requested the US's from Parkland and are awaiting them to compile them for us. Hopefully they will be ready shortly.

Thanks,
Diane

Hi,
We are planning the final head US central reading for SUPPORT on August 23-24. We need the following studies as soon as possible to be sent to Meg Cunningham:

Hi,

We are getting close to having final outcomes for SUPPORT. Thanks for all your hard work. I have attached the BPD queries and an explanation for the queries to the email. In addition, we are missing the following primary outcomes for SUPPORT listed below.

Again, thanks so much for all the hard work and effort!!
Regards,

Rose

RTI INTERNATIONAL | **Memorandum**

~~August 11,~~September 18,~~-~~2009

TO: Ron Goldberg, MD
Principal Investigator NICHD NRN
Duke University

FROM: Abhik Das, PhD
Principal Investigator, NICHD NRN Data Coordinating Center
RTI, Rockville, MD

SUBJECT: NICHD NRN Site Visit

Dear Dr. Goldberg,

At the request of the NICHD NRN Program Officer, Dr. Rosemary Higgins, we have scheduled a follow up site visit for Duke University on September ~~2nd and 3rd~~29,~~-~~2009 to review site performance and conduct chart reviews related to primary outcome data for the SUPPORT trial. Aside from Dr. Higgins, the monitoring team will consist of the following individuals from RTI: ~~Dr. Abhik Das, Ms. Margo Brinkley,~~ Jenny Auman(?), Carolyn Huitema, ~~Amanda Irene~~ and Kris Zaterka-Baxter.

We plan to arrive for the site visit at ~~8~~9:00 am on ~~Wednesday~~ September 29nd and leave by 4:00pm ~~on Thursday September 3rd~~. We would very much appreciate it if you can have some space available for the ~~full two days~~day for the team to conduct case reviews. A research team member should also be available (on call) to answer questions that may arise but will not need to be present during the case reviews.

The following is the tentative agenda for both days:

September 2

- NICU tour (please schedule this at your convenience and to help us avoid any unnecessary disruption on your unit)
- ~~8~~9:00 – 9:30 General overview of issues identified on prior site visit to include:~~NICU and Follow UP research organization at Duke University~~
- 9:30 – 11:00 Data collection and data flow issues
  - Data collection
  - NICU/FU data entry
  - QA/ edits
- 11:00 – 12:00 Overview of IRB
  (Documentation of recent IRB initial submission dates, revisions, and final approval dates for Late hypothermia, Term near term BP, ELBW BP, and aEEG for Duke and UNC site in addition to the INS-1 Duke Regulatory Binder)
- 12:00 – 1:00 Lunch

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

- 1:00 – 5:30 Overview of chart organization and case review (please have the following records available):
  - Medical Record Charts (electronic or paper version)
  - Research Charts
  - Completed Case Report Forms
  - Regulatory Binder for the INS-1, Early BP, Preemie aEEG and Term Hypotension studies (if only available for review in your regulatory office, please schedule time at their convenience so we may review the documents)
  - Support Study Binder (all versions of the study protocol, manual and case report forms)

We will review individual patient records for the following patients:

September 3

- 9:00 – 12:00 Continuation of Case Review
- 12:00 –1:00 Lunch
- 1:00 – 3:00 Continuation of Case Review
- 3:00 – 4:00 Summary Discussion: Please allow approximately one hour towards the end of the day so the monitoring team can summarize the review and discuss any relevant findings. All research staff are invited to be present, including yourself.

Thank you in advance for helping us assure the quality and accuracy of NRN study sites Please feel free to contact me at (301) 770-8214; or adas@rti.org if you have any questions.

Subject: Duke Site Visit Agenda
Date: Tuesday, August 11, 2009 6:08:25 PM
Attachments: Final Duke Agenda.doc
Duke site visit cases for review..htm

Hi Rose,

Here is a draft of the agenda for the Duke site visit; two questions:

1. I was not sure if you wanted this agenda/memo coming from you or the DCC on your behalf so please take a look and the letter header and the text in the first paragraph
2. I was not sure if Ricki Goldstein and the new FU coordinator should be present at least for the first half of the first day and the summary at the end; if so, then I need to add them to the 'cc' line.

Additionally, attached is the email I sent Gloria earlier today so she could start to pull charts from medical records. Please note I correct the duplicate ID and notified Gloria.

Thanks,
Kris

RTI INTERNATIONAL | **Memorandum**

August 11, 2009

TO: Ron Goldberg, MD
Principal Investigator NICHD NRN
Duke University

FROM: Abhik Das, PhD
Principal Investigator, NICHD NRN Data Coordinating Center
RTI, Rockville, MD

SUBJECT: NICHD NRN Site Visit

Dear Dr. Goldberg,

At the request of the NICHD NRN Program Officer, Dr. Rosemary Higgins, we have scheduled a site visit for Duke University on September 2nd and 3rd 2009 to review site performance and conduct chart reviews related to primary outcome data for the SUPPORT trial. Aside from Dr. Higgins, the monitoring team will consist of the following individuals from RTI: Dr. Abhik Das, Ms. Margo Brinkley, Jenny Auman, Carolyn Huitema, Amanda Irene and Kris Zaterka-Baxter.

We plan to arrive for the site visit at 9:00 am on Wednesday September 2nd and leave by 4:00pm on Thursday September 3rd. We would very much appreciate it if you can have some space available for the full two days for the team to conduct case reviews. A research team member should also be available (on call) to answer questions that may arise but will not need to be present during the case reviews.

The following is the tentative agenda for both days:

<u>September 2</u>

- NICU tour (please schedule this at your convenience and to help us avoid any unnecessary disruption on your unit)
- 9:00 – 9:30 General overview of NICU and Follow UP research organization at Duke University
- 9:30 – 11:00 Data collection and data flow issues
  - Data collection
  - NICU/FU data entry
  - QA/ edits
- 11:00 – 11:30 Overview of IRB and medical records organization
- 11:30 – 12:30 Case review (please have the following records available):
  - Medical Record Charts (electronic or paper version)
  - Research Charts
  - Completed Case Report Forms

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

- Regulatory Binder for the Early BP, Preemie aEEG and Term Hypotension studies (if only available for review in your regulatory office, please schedule time at their convenience so we may review the documents)
- Support Study Binder (all versions of the study protocol, manual and case report forms)

We will review individual patient records for the following patients:

CENTER	NETWORK	DOB
19	(b) (6)	[redacted]

19		

- 12:30 – 1:30 Lunch
- 1:30 – 5:30 Continuation of Case Review

<u>September 3</u>

- 9:00 – 12:00 Continuation of Case Review
- 12:00 –1:00 Lunch
- 1:00 – 3:00 Continuation of Case Review
- 3:00 – 4:00 Summary Discussion: Please allow approximately one hour towards the end of the day so the monitoring team can summarize the review and discuss any relevant findings. All research staff are invited to be present, including yourself.

Thank you in advance for helping us assure the quality and accuracy of NRN study sites Please feel free to contact me at (301) 770-8214; or adas@rti.org if you have any questions.

Subject: Duke site visit cases for review.
Hi Gloria,

These are the cases we will be reviewing. It would help tremendously if you could please flag the medical records for all data pertaining to the Support study primary outcome using posted notes in different colors for the different outcomes (i.e., red = ROP, Blue = BPD, Yellow = FU {Bayley exam}); we will be looking at data collected on the Supp05, Supp10, Supp11, NG03, NG07, PHY01, PHY02 and NF09A

CENTER	NETWORK	DOB	GEST_WKS	GEST_DYS
19	(b) (6)	[redacted]	25	1

19	(b) (6)	[redacted]	24	0
19	(b) (6)	[redacted]	24	6
19	(b) (6)	[redacted]	27	5
19	(b) (6)	[redacted]	27	1
19	(b) (6)	[redacted]	27	0
19	(b) (6)	[redacted]	27	5
19	(b) (6)	[redacted]	24	2
19	(b) (6)	[redacted]	24	2
19	(b) (6)	[redacted]	27	3
19	(b) (6)	[redacted]	25	3
19	(b) (6)	[redacted]	25	3
19	(b) (6)	[redacted]	25	1

In addition to the Support study chart reviews we will be reviewing the IRB documents (or where you are in the process) for:
Early BP
Preemie aEEG
Term Hypotension

The agenda will follow shortly; can you please confirm where we will be conducting the site visit (i.e., Hock Plaza?)

Thanks,
Kris

Hi Gloria,

Sorry, my intent was to send them on Friday but I needed help from the statistician and programmer to make sure we are pulling the right infants; I will send them hopefully by noon today.

Sorry for the delay.
Thanks,
Kris

Subject: RE: SUPPORT call

Dear Neil and Marie:

You have done a great job with the draft of the tables!

I would suggest that we start separating the tables by each treatment and control group. Thus, there would be a Table 1 for the CPAP vent study; and a Table 1 for the oxygen saturation trial. I would suggest the following:

1. Add gender and the race distribution to each of the two Tables 1.
2. Add "any surfactant" to both Tables 1.
3. Delete received PPV, surfactant DR, received chest compressions and received epinephrine from Table 1 of the oxygen saturation trial.

Table 2 for each paper should be the primary outcome as well as variations of the primary outcomes. Thus, for the ventilation study we should probably reduce the outcomes that we have on the current Table 2 to those that are the main outcomes. Alternatively, we could include primary and multiple other outcomes on the same table. It may be that we want to limit it to the primary outcomes and the pulmonary outcomes and include a Table 3 for each paper for the other outcomes such as IVH, etc.

We should list each major outcome such as NEC = 2 and IVH 3/4 by itself, as well as with the competing outcome of death.

We should also add length of stay, oxygen after discharge, and postnatal age of oxygen to the other outcomes table.

I think it is great that we are trying to finalize these tables even before we look at any results.

Best regards,
Wally

Hi all,

As far as the BPD queries are concerned, we have heard back from the following centers: 3 (Case), 12 (Indiana), 13 (Yale), 15 (Stanford), 16 (UAB), 26 (UNM). For the most part it appears that the queries have been resolved at these centers, and I will be following up in the few cases where questions remain. We have yet to hear back from the other 13 centers (all centers except Wake Forest received BPD queries).

SUPPORT Study Tables

Table 1. Patient Description

	Treatment	Control	P Value
Birth weight (grams) (M + SD)			
Gestation (weeks) (M + SD)			
Apgar 1 min < 3 Assigned			
Apgar 5 min < 3 Assigned			
Received PPV (Number, %)			
Surfactant in DR (Number, %)			
Received Chest Compression (N%)			
Received Epinephrine (N, %)			
Antenatal Steroids , Any			
Antenatal Steroids, Full			

Table 2. Other Outcomes

	Treatment	Control	P Value
Total Duration of Mechanical Vent (M +SD)			
Duration of Oxygen (Total days)			
Duration of CPAP			
Duration of nSIMV			
% alive off MV by Day 7 (+SD)			
Pneumothoraces (N, %)			
Other air leaks (N, %)			
NEC ≥ 2			
PDA requiring Surgery			
IVH Gr. III or IV or Death			
PVL			
BPD at 36 weeks (O_2 dependence)			
BPD by Physiologic Definition (N%+SD)			
Survived to discharge (N,% +SD)			
Number Never Intubated (N, %)			
Number receiving PNS for BPD (N, % %)			
Alive without neurdevelopmental impairment at (18-22 months) years (N, %, +/-SD)			

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

Table 3. Primary Outcomes

	Low Saturation	High Saturation	RR	CI	p value
Threshold ROP/Surgery or death by 36 weeks (%)					
Death by 36 weeks (%)					
Threshold ROP in alive infants at 36 weeks (%)					
BPD or Death at 36 weeks (%) By Oxygen @ 36 wks.					
BPD or Death at 36 weeks (%) By Phys. Challenge					

Table 4. Secondary Outcomes

	Low Saturation	High Saturation	RR	CI	p value
Death by discharge status (%)					
BPD in alive infants at 36 weeks (%)					
IVH 3 or 4/PVL or death by 36 weeks (%)					
IVH 3 or 4 in alive infants at 36 weeks (%)†					
Cystic PVL in alive infants at 36 weeks (%)†

Subject: FW: Request for collaborative proposal

Rose,
OK, we need a plan to minimize exploratory analyses before the papers are published. I agree. Probably even after they are published. I'm not sure the proposal we have in mind qualifies as "exploratory". A new method for ROP screening has been proposed from Sweden (and Boston) and validated in a small Swedish population. There is a need for more validation and possibly refinement of the WINROP system.

If testing the WINROP system for ROP screening were part of the planned analysis for SUPPORT or Growth, then I understand we would have to tell Drs. Binebaum and Quinn that we cannot help them. Otherwise, why not consider the proposal for collaboration? The request we made to the Steering Committee was just for permission to share the SUPPORT and Growth protocol and data forms with our CHOP collaborators. I can help Drs. Binebaum and Quinn put together a proposal for the SUPPORT and Growth subcommittees without letting them see the protocols or forms. Is this interpretation correct? There will be no costs to the Network except RTI time and effort, so unless Abhik is concerned about the analysis effort, we don't need to submit this to the SC as a concept, right? If the subcommittees like and approve the proposal, the analyses could wait until after the planned analyses for SUPPORT and Growth are completed (unless Abhik determines it would be more efficient to do them at the same time), but waiting until after the papers are published seems unnecessary.

You probably know that there is a perception outside the Network that we are unduly protective of the data and appear self serving to some. If no one in the Network has proposed this idea until now and we tell them, "Sorry, it's a good idea, but we're not finished with our own analyses," then proceed to look at this ourselves, it will look like we stole their idea. If we tell them to wait until the SUPPORT and Growth papers are published, this may be 2 years. They'll look for other collaborators, probably Pediatrix.

The idea has considerable merit; I think the Network should be eager to collaborate with the CHOP ophthalmologists. If there is already a proposal from the SUPPORT or Growth subcommittee or Network site ophthalmologists to look at this, that's different, and I'll tell them we can't help them. If I'm out of line, please tell me. I don't know all the Network rules by chapter and verse. Can we see what the SUPPORT subcommittees think of the idea, or should we tell Binebaum and Quinn to find other collaborators and another database to use to test the WINROP system? I've attached the WINROP papers again for any who haven't seen them.
Ed

We should consider putting in place mechanisms to reduce the likelihood of exploratory analyses being done before our primary and secondary papers are published.

Based on a recent publication Löfqvist et al from Lund (Arch Ophthalmol 2009; 127:622), Ed Bell is interested in collaborating with Drs. Binebaum and Quinn from CHOP Ophthalmology to evaluate growth rates and evolution/resolution of ROP. Please send a yes/no vote by August 17 to share the SUPPORT main trial protocol/forms as well as the growth secondary protocol/forms with the folks from CHOP.

Hi,
We are getting close to having final outcomes for SUPPORT. Thanks for all your hard work. I have attached the BPD queries and an explanation for the queries to the email. In addition, we are missing the following primary outcomes for SUPPORT listed below.

Again, thanks so much for all the hard work and effort!! You guys have been fantastic!!!!
Regards,
Rose

ABSTRACT

Backrgound

The purpose of this study was to quantify the time, effort, and rate of success involved obtaining antenatal consent to enroll infants into the Neonatal Research Network SUPPORT trial, and to determine if these infants were representative of the eligible population.

Methods

Eligible subjects were those likely to deliver in the SUPPORT gestational age window (24-27 6/7 wks). Data included who approached them for consent, how often they were approached, the duration of each contact, whether consent was obtained and if the infant(s) was enrolled in the trial. Eligible, non-enrolled infants entered into the NRN Generic database were identified to allow comparison of enrolled and non-enrolled infants.

Results

2828 women were identified at 18 sites between October 2005 and February 2009. 2228 were approached for consent and 1217 (54.6%) agreed. For 77% of those approached, < 3 visits were required to complete the consent process. (mean 2.0 +/- 1.2). Of the 655 infants delivered within the study window, 610 of were enrolled. Mothers who received a neonatal consult were more likely to give consent ($p<.001$). The percentage of mothers not treated with steroids was significantly greater in the non-approached vs. the approached group (20.3%, 3.4% $p<.001$).

Conclusions:

In a trial of preterm infants requiring antenatal consent, more than 5 women were identified as likely to deliver a baby in the GA window for each one who delivered an enrolled infant. The differences between enrolled and non-enrolled infants highlight the difficulties in attempting to recruit a representative population for prospective trials requiring antenatal consent.

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

Introduction:

Informed consent ensures that subjects enrolled in research trials are appropriately informed as to the risks and benefits of the trial, came to the trial voluntarily, and represent an accurate cross-section of all subjects who would potentially receive benefit from or undergo the risks of the studied intervention. Traditionally, this consent is obtained directly from the subject when they are in condition to understand and participate in the process. In conducting trials on infants who will receive an intervention at or near the time of birth, the process requires approaching families prior to delivery.

Funding for clinical trials sponsored by federal agencies and industry is often based on a model of capitation where a site is paid based on the number of subjects enrolled plus some time allotted for screening. However, because prospective data comparing the number of families who are approached in the antenatal period to the number of infants who are actually enrolled have not previously been available, the current model may not adequately account for time spent by study staff to screen, approach and enroll all eligible subjects.

Early enrollment in the Surfactant Positive Airway Pressure and Pulse Oximetry Trial in Extremely Low Birth Weight Infants (SUPPORT) demonstrated that antenatal screening and consent were labor intensive and that actual patient enrollment numbers differed significantly from the screening and consent numbers. Thus, this secondary study was designed to evaluate the antenatal screening and consent process to determine the factors that contribute to successful enrollment of patients in a complex trial conducted by an experienced multi-center trials network. The second objective of the study was to determine whether the subjects enrolled in the trial were representative of the overall eligible population.

Methods:

This is a prospective cohort study of the antenatal consenting practices of research personnel in the multi-center Neonatal Research Network (NRN) funded by the Eunice Kennedy Shriver National

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

Institute of Child Health and Human Development (NICHD). Data for this study were collected during the second half of the NRN SUPPORT trial. The SUPPORT trial was designed to compare the use of early Continuous Positive Airway Pressure (CPAP) initiated in the delivery room to early intubation and surfactant given within the first hour of life, and to compare randomization to 2 different target SpO2 ranges during receipt of supplemental oxygen up to 36 weeks post menstrual age (PMA). Eligible infants were 24 0/7ths to 27 6/7ths weeks gestational age (GA) without known malformation for whom full postnatal treatment was planned.

Eligible subjects for the antenatal consent secondary study were those women who the Obstetrical/Perinatal staff felt were likely to deliver in the SUPPORT gestational age window. Clinical data were collected by trained research coordinators, and all analyses were performed at a central data coordinating center (RTI International, Research Triangle Park, NC). Research staff collected study data using a one page data collection form. If the parent(s) were not approached for consent, the reason they were not approached was recorded. If they were approached, the staff recorded the total number of times the parent(s) were approached, the number of such attempts which were made by the research coordinator/RN, and whether OB permission was obtained to approach for antenatal consent. As a neonatal consult is often performed on this population, staff recorded whether a consult was performed, whether the consent was discussed during the consultation, and whether consent was obtained at the time of the consult. In some centers the Institutional Review Board required a consult be completed prior to consent, so this was also recorded. Women who were approached were asked if they were approached for participation in any other studies for themselves or their infants. Finally, the study staff was asked to estimate the time required to obtain a decision regarding consent.

Data were collected at each of the 18 NICHD NRN centers until fifty mothers had delivered within the window at the center. Data forms were keyed by the centers and transmitted electronically to the DCC. Infants born at Network centers who delivered in the SUPPORT window were entered into the NRN Generic Database (GDB) which, before 2008, collected delivery and demographic data on

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

infants between 401 and 1500g inclusive birth weight that were inborn at NRN centers or admitted to the NICU within 14 days of age. Beginning in 2008, the database collected infants who were 1) inborn and between 401 grams and 1000 grams inclusive birth weight and/or 2) inborn and between 22 0/7 and 28 6/7 weeks (<29 weeks) inclusive gestational age. GDB data were used to evaluate whether infants enrolled in the SUPPORT trial represented the eligible NRN population.

To determine the representativeness of the population enrolled in the SUPPORT trial, data from the GDB were obtained for those infants born at NRN centers during the period of SUPPORT trial enrollment who qualified to participate in SUPPORT. Eligible but non-enrolled infants had information collected on prenatal care, the use of antenatal steroids and demographic data. These data were compared for infants who were or were not enrolled in SUPPORT to assess whether the trial had enrolled a representative sample of the available population. In addition, comparisons were made between eligible infants whose mothers were or were not approached for SUPPORT.

We performed bivariate statistical analyses using Chi-Square and Student's t-tests. All statistical analyses were performed using SAS version 9.1.3 (SAS Institute Inc., Cary, NC). A p value of less than 0.05 was considered statistically significant. This trial was approved by the Institutional Review Boards of all participating centers as well as that of RTI.

Results

Between October 2005 and February 2009, a total of 2828 women were identified at 18 NRN centers as being at risk for delivering a premature infant between 24 to 27 6/7 wks GA and were otherwise eligible for participation in the SUPPORT trial. Two NRN centers did not participate in the antenatal consent trial and 4 participating centers did not identify 50 eligible women between the start of data collection for the antenatal consent study and the end of the SUPPORT trial. Four centers identified more than 50 women (mean 82) before they were told to stop collecting data. All data collected by participating centers have been included in this analysis. Analysis using only the first 50 women from the centers that

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

over-enrolled were not significantly different. Screening, enrollment and consent numbers by center are presented in Figure 1.

2228 women were approached for informed consent. The two most frequent reasons for not attempting to obtain consent were early discharge and a lack of time prior to delivery (Table 2). Common choices within the "other" category in the table were early discharge, the inability of the mother to give consent, fetal abnormalities, and language barriers that made informed consent impossible. Mothers were considered unable to give consent when in active labor, being too young, and having either a mental or physical health issue which precluded them being approached. A study coordinator or research RN made 75% of all approaches. For 77% of those women approached, consent was attempted < 3 times. (Overall mean 2.0 +/- 1.2). The frequency of approaches ranged from 1 (n=900) to 11 (n=2) times. The median time spent to obtain a decision regarding consent was less than 1 hour regardless of the decision. The estimated GA at time of screening was not significantly different for those who consented versus those who did not. Of the 2228 mothers approached, 1217 (54.6%) gave consent, and 578 subsequently delivered within the SUPPORT study window. Of these, 535 delivered infants who were enrolled (Figure 2). Forty-five consented infants born in the GA window (7%) were not enrolled, usually due to lack of staffing, equipment, or time. Only 19% of those mothers screened delivered infants who were subsequently enrolled in the study. A neonatal consult was performed in 70% of cases. Mothers receiving a neonatal consult were more likely to consent ($p < .0001$), but consent was obtained during the consult in only 12%. Centers that were NICHD Maternal Fetal Medicine network centers enrolled at a higher and were more likely to require less than 30 minutes to obtain a consent decision. The median time spent to obtain a decision regarding consent for all centers was less than 1 hour regardless of the decision.

Infants of non-approached and approached mothers were different in several important ways (Table 2). Infants of approached mothers were significantly more likely to be non-Hispanic white ; to be older, and to have a high school education , medical insurance, and at least one PNC visit. A

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

significantly higher proportion of eligible non-enrolled infants not approached had no exposure to antenatal steroids compared with infants whose mothers were approached (20.3% vs 3.4%, p<.0001). Maternal gravidity and parity were not significantly different between these groups.

Infants who were enrolled in SUPPORT and those who were not enrolled were also significantly different. Non-enrolled infants had mothers who were significantly less likely to have insurance and to have received prenatal care and were over 4 times more likely to have gone without antenatal steroids (15.7% vs. 3.8%) (Table 3).

Discussion:

To our knowledge this is the first neonatal study to evaluate the time and efforts required to approach and obtain antenatal consent from parents for the enrollment of their unborn infants. Our results reveal that 5 families needed to be identified and screened for every one infant successfully enrolled. Only 47% of women consented went on to deliver infants in the study window. Though the time needed to obtain consent was collected as a discrete variable, we found that the median was between 30 minutes and 1 hour. Multiplying these bounds by the number of women approached for each enrolled infant (3.7) yields a value for coordinator time required to obtain an enrolled infant at between 1.8 and 3.7 hours. Assuming that the enrollment rate of the SUPPORT trial was equivalent in the first half (the part not included in this analysis) suggests that over 2400 hours were spent screening greater than 6000 women to enroll 1317 infants in the SUPPORT trial. This includes time spent approaching women who did not consent and consenting women who did not deliver in the window. It does not account for time spent screening women who were not approached for consent.

Morley et al reviewed parental willingness to participate in multiple trials in the neonatal period and found that most (74%) were willing to allow their baby to participate in multiple trials. [1] We had concerns that the burden of being approached for multiple trials, especially since 5 centers also belonged to a maternal/fetal research network, would affect the enrollment in SUPPORT. We found

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

that only 8% of women had been approached for another trial at the time of the SUPPORT consent discussion, probably because it was an antenatal consent and the window was early in gestation.

Because of the unique attributes of the NRN, we were able to obtain demographic data from the GDB for infants who were delivered in the SUPPORT window but were not enrolled in the study. Thus, we were able to compare infants who were vs. were not enrolled and those whose mothers were vs. were not approached. These groups differed in a number of significant areas. Most importantly, infants born to women who were not approached for consent were almost 6 times more likely not to have been exposed to antenatal steroids, an intervention known to be associated with better short and longer term outcomes for preterm infants. [2] They were also more likely to be more immature and their mothers were significantly less likely to have insurance and to have received prenatal care.

In a review of NIH funded interventional randomized controlled trials, Charlson and Horwitz found that only half such trials kept any data on subjects who were eligible but not enrolled, and for those trials which collected data only 27% of eligible non-enrolled subjects were a result of subject refusal.[3] The Consolidated Standards for Reporting of Trials (CONSORT) is a document created with the intent of standardizing items reported in trial publications, including a checklist for necessary items and a flow chart of participants.[4,5] The standards require the quantifying of eligible populations but make no such requirement for identifying the demographics of this group or its similarity to the enrolled or consented populations. Research from the California Department of Health Services reviewed the effect of the introduction of tandem Mass Spectrometry (MS/MS) to the California Newborn Screening program.[6] This involved another test on an already collected blood spot, for which it was decided informed consent was necessary. They found that the burden of adding informed consent to the screening process resulted in only 50% of infants being screened for the new test. Twenty one percent of participating hospitals did not offer the screening because of the burden of providing informed consent. It is very possible that failure rates for enrollment of infants in trials that require consent in the antenatal period is much higher than is currently believed. Following the CONSORT standards in all

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

antenatal consent trials, both consented and waived, and obtaining basic demographic information for all eligible infants will help us understand whether similar reduction in enrollment occurs when the burden of consent is added to these trials and whether the enrolled infants are representative of the true eligible population.

Blinding and randomization have always been the benchmarks for protecting trials from bias. Investigators have shown that trials in which allocation to a study group is well concealed more accurately reflect the true study effect than those not well concealed.[7] However, these controls only protect the trial from internal bias, not the selection bias we have seen. Manning and Silverman have voiced concerns about selection bias, stating that a disproportionate number of vulnerable and deprived families are involved in clinical research.[8,9] Harth and Thong questioned parents who had volunteered in an asthma trial in Australia and concluded that volunteering parents were "significantly more socially disadvantaged and emotionally vulnerable." [10] In a study of recruitment and retention of premature infants into an early intervention program, Constantine et al found significant enrollment bias in this direction related to race, weight and site. [11] Mitchell and Kline, on the other hand, showed a significantly greater proportion of African-Americans, uninsured patients, and Medicaid recipients in the non-participant group in a minimal risk emergency department study.[12] Aagaard-Tillery and the NICHD Maternal Fetal Medicine (MFM) network found that blacks and Hispanics were significantly less likely to allow use of their genetic samples for future studies.[13]

Glassberg, Luce and Matthay analyzed the screening and enrollment of a trial of acute lung injury in two San Francisco hospitals, one an academic referral center and the other the public hospital for the city. [14] The percentage of screened infants enrolled was nearly 3 times higher in the academic center, a statistically significant difference ($p<.0001$). All of the centers in our trial were academic centers, but many included a relationship with a non-academic center. All of these reports point toward the need to find a better method of enrolling truly representative populations in multicenter trials evaluating better practices.

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

Our analysis would suggest that under-privileged subjects were less likely to participate. Because this trial enrolled subjects from 18 academic centers with long-term experience in randomized trials and a broad mix of racial, ethnic, and socio-economic populations, it is not likely that the bias involved represents an intention to include or exclude any group. The logical conclusion is that the many subjects who ended up excluded from this trial, despite the significant time and effort spent by the coordinators to include them, represent a failure of, or an innate problem with, the antenatal-consent process itself. Our observations, along with previous experience in a trial of a delivery room intervention[15], suggest that it is appropriate from an ethical perspective to allow trials that compare standard of care interventions to waive the consent process until after birth. This would ensure that the infants enrolled in such a trial do not differ significantly from the overall eligible population and insure the generalizability of the results.

Conclusion

Our prospective analysis of the process of antenatal consent enrollment in the NICHD Neonatal Research Network SUPPORT trial has shown that antenatal screening and consent are labor intensive, that actual patient enrollment numbers may be significantly lower than screening and consent rates, and that the population enrolled as a result of antenatal consent may not be representative of the total eligible population. In this complex interventional trial of preterm infants, nearly 5 women were identified as likely to deliver a baby in the window for every infant enrolled in the trial. Antenatal steroid use was significantly higher among infants enrolled in the SUPPORT study compared to those who were eligible but not enrolled, with a similar difference between infants born to approached and non-approached women. Along with quantifying the time and expense of antenatal consent, these observations point out the difficulties in attempting to recruit a representative population for prospective trials requiring antenatal consent and suggest that greater use of waiver of consent for trials that are low risk may be appropriate for future studies.

Ok, that's the problem then. Since this patient was < 1000g at birth (and their window date opened after the follow-up criteria changed), they should have had the NF forms completed. Please delete any SF forms keyed in the Support system and key them as NF forms in the 18 month Follow-up system.

This patient will also require an NF10 form keyed with the status of Lost to Follow-up. Let me know if you have any further questions!

FYI, you should not have any future Support follow-up visits that require the use of the SF forms. Only the NF forms should be used from this point onward.

Thanks,
Jenny

Hello Jenny,

The data entered into the system was Form SF12 V02, it was entered today. We just found out about Form NF12, NF01 we are going to enter these data into the system soon.

Thanks,

Gloria

Hi Gloria,

I don't see any Follow-up cases that could possibly be GDB ID (b) (6) in the 18 month follow-up data. Could you please take a look at the data management system and see if you can find this case? If not,

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

please key the NF forms. You will enter the patient's GDB Network ID on the NF00.

Thanks,
Jenny

Hi Gloria,

I just spoke with Rose regarding the missing data reminders you have been receiving for SUPPORT infant (b) (6) and I think I can help clear things up. I looked up the infant's ROP data on the SUPP10 and found that the left eye was reported as mature on the (b) (6) exam. However, the right eye was reported as having the lowest zone of any vessels =2 and the highest stage in lowest zone =4 (stage 4 ROP). Because the infant had reached final status in both eyes according to the data (mature left eye, ROP in right eye), you actually did not receive a missing ROP data reminder last time (b) (6) However, if the data for the right eye are incorrect and the infant did in fact have mature vessels in the right eye as well, please edit the data accordingly.

I also tried to look at the infant's follow up data, however, I could not see that any had been entered, including the NF01, and I did not see a follow up ID for the infant. That could be because the forms have not been entered, or there could be some other issue that is preventing us to link the GDB records with the correct follow up ID. I am copying Jenny Auman, because if the latter is true she can help us figure out what the problem is.

If you have any questions, please let me know.

Thanks,
Marie

See the note below -

I am become concerned given the inositol urine issue and now this (which was serendipitously discovered today). I know we are really busy but perhaps we need to discuss. This was a baby before Gloria's time so may be relative to the prior coordinator.

Let me know what you think

HI,

I spoke to Gloria over the phone about this SUPPORT baby. This was an infant from 2007 for whom she was trying to complete the data entry. Please see below - this child apparently had mature retina and got coded as a 4 under the ROP column (instead of the zone column) on the data entry. Thus, this infant would have been classified as severe ROP instead of resolved ROP (primary outcome of the study). Please insure that the data are being coded and keyed correctly.

Thanks for your attention to this.

Hi Gloria,

I just spoke with Rose regarding the missing data reminders you have been receiving for SUPPORT infant(b) (6), and I think I can help clear things up. I looked up the infant's ROP data on the SUPP10 and found that the left eye was reported as mature on the(b) (6) exam. However, the right eye was reported as having the lowest zone of any vessels =2 and the highest stage in lowest zone =4 (stage 4 ROP). Because the infant had reached final status in both eyes according to the data (mature left eye, ROP in right eye), you actually did not receive a missing ROP data reminder last time (b) (6) However, if the data for the right eye are incorrect and the infant did in fact have mature vessels in the right eye as well, please edit the data accordingly.

I also tried to look at the infant's follow up data, however, I could not see that any had been entered, including the NF01, and I did not see a follow up ID for the infant. That could be because the forms have not been entered, or there could be some other issue that is preventing us to link the GDB records with the correct follow up ID. I am copying Jenny Auman, because if the latter is true she can help us figure out what the problem is.

If you have any questions, please let me know.

Thanks,
Marie

Rose,

This is my draft, which I welcome you to edit. There are word limits you will notice.

Also attached is what I submitted for last year's iNO session for comparison.

I am attending a PPG review almost all day today, so after editing, I am fine for you to circulate to

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

Neil and Wally (just cc me, so I know when we have the feedback and hopefully I can get this to Jim Kiley (Div Lung Diseases director) tomorrow.
The speakers (moderators) don't have to be committed yet.
If you think other literature should be here for the ATS committee to understand the field that are different than the 3 I suggested—feel free to replace.
Also, please fill in the pulse ox target ranges.

Session Information

Title Outcomes from the NHLBI-NICHD SUPPORT Trial: The Surfactant Positive Airway Pressure and Pulse Oximetry Trial in Extremely Low Birth Weight (ELBW) Infants

Target Audience *e.g. For providers of lung health? Specific Assemblies? Serving a specific patient group or multiple groups? Will your learners have clinical, research, administrative responsibilities? Do they need to learn about areas of medicine outside of their specialty?*

pulmonologists/neonatologists/pediatricians

Should attendees have specific expertise to benefit from this session? ☒ yes (clinical) ☐ no

Session Summary Include a brief summary of the course content, from the perspective of the learner, which runs no longer than 75 words.

~~Extremely low birth weight (ELBW) premature neonates suffer from higher~~increased ~~rates of morbidity and mortality and increasing rates of pulmonary morbidity compared to term newborns.~~ Advances in therapy for the very premature ~~have~~ suggested that mode of ventilation and oxygen toxicity increase risk of bronchopulmonary dysplasia ~~(BPD)~~ and retinopathy of prematurity ~~(ROP)~~. We will present ~~Results will be presented from the~~the results of the NHLBI / NICHD SUPPORT trial ~~– a prospective, randomized, factorial 2x2 design large multi-center trial~~ that tested early CPAP and a permissive ventilation strategy versus early surfactant and a standard ~~and mechanical~~ ventilation ~~management~~ strategy and also compared a ~~with a~~ low or high pulse oximetry target on outcomes of survival without BPD, ~~and~~ ROP, and neurodevelopmental impairment.

Have you served as faculty for a similar session before? ☒ yes ☐ no

Organization Name National Heart, Lung, and Blood Institute and National Institute of Child Health, NIH

Statement of Clinical/Scientific Importance Please state in 250 words or less the educational need for this session to be presented to ATS International Conference attendees. Identify the methods you used in determining this need by checking appropriate boxes below, rather than stating them in narrative.

1 What is that difference between current and optimal practice you wish to address with education? (This is called the professional practice gap.)
2 In order to narrow or eliminate the gap will your offering increase knowledge, competence (knowing how to do something), performance in work or practice or patient health/quality of life?

1) Current practices in neonatal intensive care units for very preterm infants ~~(NICU) is variable on the~~

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

include the use of early continuous positive airway pressure (CPAP) ~~as an alternative to conventional ventilation, which permits~~or the ~~-~~early use of surfactant (a known beneficial treatment to prevent respiratory distress syndrome and BPD), two approaches that have not been prospectively compared. In addition, no studies have compared the use of lower versus higher pulse oximetry targets for such infants and at present there is little high level evidence to choose between these alternatives based upon important clinical outcomes such as retinopathy of prematurity. ~~many clinicians in many~~ NICUs ~~have practices that permit oxygen saturation targets in the mid 80% range to reduce the incidence of ROP.~~

2) The SUPPORT trial was designed to ~~close the gap on knowledge of the most effective strategies for the support of breathing and oxygenation~~address these two important practices in the very preterm infant. The ~~effect~~ efficacy of the ~~alternative~~ less invasive mode of ventilation (CPAP) without early use of surfactant compared with early surfactant combined with either a low (85-89%~~—~~) ~~vs.~~or high (91-95%~~—~~) pulse oximetry ~~management~~ target has not previously been studied in ~~a~~ prospective randomized ~~fashion~~trials. Neonatal Network investigators will present the results of the SUPPORT trial which enrolled over 1300 infants and moderators will lead a discussion of the evidence, which could inform clinical practice for the ELBW infant. The ~~P~~primary outcomes ~~-~~of BPD and ROP will be presented.

Please cite 2 or 3 resources or references that could be reviewed by the Program Committee as evidence of need, if requested.

☐Formal needs assessment(s) by scholarly investigators

☐Other

Can these data be applied to learners at the International Conference? ☒ yes ☐ no

Objectives Please provide three learning objectives below:

Your objectives should focus on closing the gap/solving the problem you identified under the Statement of Clinical/Scientific Importance. E.g. what will the learner be able to do/do better after attending your session? You may begin some of your objectives with the following: "will be able to describe"; "will learn new findings about..."; "will appreciate the importance of...". At least one of your objectives should state how the learner will be able to apply new knowledge competence or performance/skill to his practice or work or improve quality of life or health of the patient. Eg. "will be better able to diagnose..."; "more appropriately refer..."; "refer earlier..."; "will have new strategies to manage the care of..."; "will integrate new treatment options in discussing xxx with the patient..."; "will be able to improve the quality of life/health status of his patients by xxx."

At the conclusion of this session, the learner will be able to:

1. To learn the impact of early CPAP on BPD and ROP in the SUPPORT trial
2. To learn the effect of high vs. low pulse oximetry targets on risk of BPD and ROP in the ELBW infant
3. Understand the interaction of mode of ventilation and target pulse oximetry on outcomes of BPD and ROP in ELBW infants.

Initial Disclosure of Faculty Conflicts of Interest

ATS International Conference requirements for disclosure and management of conflict of interest are based upon the ATS

Policy on Management of Conflict of Interest and **Policy on Tobacco Relationships.** Session proponents must complete the questions below as an initial disclosure. If the session is approved, session organizers, chairs and presenters will complete a detailed disclosure form and appropriate ATS oversight committees will review the disclosures as part of their oversight of sessions.

Please note:

- Many individuals have competing interests that may cause conflicts of interest. A COI depends on the situation and not on the character or actions of the individual. Examples of potential conflicts include personal financial relationships with commercial entities, or government or foundation funders, that are relevant to the session, including employment by a commercial entity; consultancy(ies); Board or Advisory Board; lecture fees; service as an expert witness; research grants; patents received or pending; royalties; and stock ownership or options (excluding mutual funds unless a sector fund concentrated in an industry[ies] relevant to the activity).
- The ATS "Policy on Tobacco Relationships" requires that individuals with a current tobacco industry relationship (or one in existence between now and the conclusion of the 2010 International Conference) not serve as a session planner (organizer), chair or presenter. (If limited to personal holdings of tobacco stocks or options, divestiture of such holdings a minimum of 30 days before the conference restores eligibility. See the policy for details.)
- Disclosure of a real or potential COI will not automatically invalidate a session proposal.

Session Proposer

1. Do you, as the proposer, have a personal financial interest(s) in a commercial entity (such as a pharmaceutical company or medical device manufacturer) that might be perceived as a real or potential conflict of interest (COI) relevant to the subject matter of this proposal?

   ☒No ☐Yes

2. Do you, as the proposer, have a personal financial interest(s) in a non-commercial entity (such as support from a government source or foundation or other non-profit source) that might be perceived as a real or potential conflict of interest (COI) relevant to the subject matter of this proposal?

   ☒No ☐Yes

3. Do you, as the proposer, have knowledge of your institution or employer having a significant financial relationship with a commercial entity that might be perceived as a real or potential conflict of interest (COI) relevant to the subject matter of this proposal?

   ☒No ☐Yes

4. Do you, as the proposer, have a relationship with a tobacco entity at present, or may within the twelve months prior to the conference?

   ☒No ☐Yes

Proposed Faculty

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

1. To your knowledge, does any other member of the proposed faculty (presenters) have a personal financial interest(s) in a commercial entity (such as a pharmaceutical company or medical device manufacturer) that might be perceived as a real or potential conflict of interest (COI) relevant to the subject matter of this proposal?

   ☒No ☐Yes

2. To your knowledge, does any other member of the proposed faculty (presenters) have a personal financial interest(s) in a non-commercial entity (such as support from a government source or foundation or other non-profit source) that might be perceived as a real or potential conflict of interest (COI) relevant to the subject matter of this proposal?

   ☒No ☐Yes

3. To your knowledge, does the institution or employer of any other member of the proposed faculty (presenters) have a significant financial relationship with a commercial entity that might be perceived as a real or potential conflict of interest (COI) relevant to the subject matter of this proposal?

   ☒No ☐Yes

4. To your knowledge, does any other member of the proposed faculty (presenters) have a relationship with a tobacco entity at present, or may within the twelve months prior to the conference?

   ☒No ☐Yes

To: Walsh, Michele
Subject: SUPPORT SDB ancillary

Hi Michele,

I've attached the revised protocol and my response to the protocol committee. If you could take a peak, I would really appreciate it, particularly with regards to how I have handled the "exploratory analysis" of the kids with MRI's and also the budget.

Nancy told me the standard research nurse rate was $35/hr, so I put that in my estimates, but I don't know what the standard rates are for data entry and data analysis, so I just gave time estimates.

Please let me know if there is anything I should change. Otherwise, could you send these files back to the NRN or let me know who to send them to?

THANKS! -AMH

***REVISED* PROPOSAL FOR SUPPORT ANCILLARY STUDY:**

PRE-SCHOOL SLEEP-DISORDERED BREATHING

Anna Maria Hibbs, MD, MSCE

Case Western Reserve University, Rainbow Babies and Children's Hospital

RESUBMITTED July 15, 2009

Abstract/Synopsis

Premature infants are at increased risk of sleep disordered breathing (SDB) when they reach school-age (8-11 years) and young adulthood.[1, 2] SDB may adversely impact health, cognition, and behavior in children.[3-21] Furthermore, animal models and some limited human data seem to suggest that fetal and neonatal hypoxia could alter respiratory responses and lead to SDB later in life.[1, 22-35] The 5-6 year-old follow-up for the SUPPORT trial would be an ideal opportunity to (1) assess the prevalence of SDB in a large national VLBW population and (2) assess the long-term safety of lower target saturation ranges in the NICU.

Statement of Problem

SDB affects 1-2% of children.[2, 36] SDB may occur due to airway obstruction from large tonsils or abnormal airway size or tone, or it may result from altered sensing or response to hypoxia or hypercapnia. SDB has been linked to hypertension,[14] growth failure,[5] enuresis,[21, 37] and impairment of cognition, attention, and executive functions.[4, 6, 8, 11, 38-40] In fact, the association between SDB and neurocognitive abnormalities is stronger in children born preterm.[8] Identification of children at high risk for SDB and its associated morbidities is particularly important given the growing body of evidence that treatment with adenotonsillectomy may improve quality of life and neurocognitive function.[7, 15, 16, 21, 41, 42]

Children born preterm are especially vulnerable both to SDB and its sequelae. In a Finnish cohort study, very low birth weight (VLBW) infants were shown to have a two-fold risk of SDB as young adults.[1] Previously published data from the Cleveland Children's Sleep and Health Study (CCSHS) demonstrated that former preterm children have a three- to five-fold increase in the odds of SDB at 8-11 years of age compared to their term peers.[2] Furthermore, the association between sleep disordered breathing (SDB) and childhood cognitive impairment is stronger in preterm than term infants.[8] The mechanisms by which prematurity predisposes children to SDB are unknown, although there is some evidence that early exposure to hypoxia (or hyperoxia) may permanently alter respiratory responses and predispose infants to SDB later in life.[22-35]

Thus, SDB could be an important safety outcome of the target saturation arms of the SUPPORT trial. In addition, this large national cohort of preschool-aged VLBW children would be a unique opportunity to better understand the natural history of SDB in preterm infants and assess the burden of disease in this age group, as SDB has previously been documented in older children (8-11 years old) and in young adults.[1, 2]

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

Hypotheses

(1) At 5-6 years of age, children born VLBW will have a higher prevalence of SDB compared to the general population.

(2) Infants randomized to the lower saturation group will have higher scores on the Sleep Related Breathing Disorder (SRDB) scale.[43, 44]

(3) *Infants randomized to CPAP will have lower scores on the SRDB scale.*

(4) Infants with more frequent desaturations *below 80%* will have higher scores on the SRDB scale.

(5) Perinatal and neonatal risk factors associated with SDB will include: black race, maternal smoking during pregnancy, *maternal hypertension* during pregnancy, and caffeine use. Gestational age, birth weight, SNAP score, days of the ventilator, and bronchopulmonary dysplasia, will not be associated with SDB.

(6) Childhood SDB will be associated with concurrent MRI abnormalities (such as hippocampal atrophy), but not with MRI abnormalities in infancy.

Specific Aims

(1) Describe the prevalence of SDB symptoms in 5-6 year old children born VLBW.

(2) Assess differences between the saturation arms of the SUPPORT study in SDB prevalence at *6-7* years of age.

(3) Determine whether infants with a higher percentage of desaturations *below 80%* are more likely to have SDB symptoms at *6-7* years of age.

(4) *Assess difference between the CPAP and intubation arms of the support study with regards to SDB prevalence at 6-7 years of age.*

(5) Determine whether previously identified risk factors for SDB in older cohorts are also risk factors for SDB in *6-7* year old VLBW children.

(6) *Explore the association between childhood SDB in VLBW infants and MRI abnormalities, at near-term and at 6-7 years of age.*

Rationale/ Background

Among infants born preterm, increased rates of SDB have been documented at school age and in young adulthood.[1, 26] In the CCSHS cohort, traditional markers of neonatal severity -- such as lower birth weight, days on the ventilator, BPD, and sepsis -- were not associated with an increased risk of SDB.[26] Black race and having a single mother were associated with increased risk of SDB, suggesting both genetic and socioeconomic factors may play a role. In race-adjusted analyses, mild maternal pre-eclampsia was significantly associated with an increased odds of SDB [OR 7.56 (1.66-34.48). A history of xanthine use was significant in unadjusted analyses [OR 2.43 (1.01-5.87)], with a

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

race-adjusted odds ratio of 1.94 (0.79-4.78). An association with xanthines could potentially indicate either a medication effect or be a marker of certain patients with underlying life-long differences in respiratory drive manifesting as both SDB and apnea of prematurity. Alternatively, xanthines may be a marker of neonatal apnea and intermittent hypoxia; pre-ecclampsia itself may be a marker of *in utero* hypoxia and/or ischemia. Similarly, maternal smoking during pregnancy may cause placental insufficiency and fetal hypoxia. In the young adults born VLBW, Paavonen et al found that maternal smoking during pregnancy was associated with SDB [OR 2.64 (1.17-5.97)].[1] Although maternal smoking during pregnancy was not a statistically significant risk factor for SDB in the CCSHS cohort, the point estimate was similar [OR 2.09 (0.96-4.55)].[26] If early hypoxia does indeed put preterm infants at increased risk for SDB later in life, the SUPPORT population would be an ideal group in which to test this hypothesis, both by assessing differences in SDB between the two saturation groups, as well as by assessing whether an increased amount of time spent below the targeted saturation ranges was associated with SDB.

Intubation and degree and duration of respiratory support could be important risk factors and/or potential confounders. In the Finnish study of young adults, there was no association between SDB and a history of mechanical ventilation.[1] However, in the Cleveland Children's Sleep and Health Study (CCSHS), there was a non-significant suggestion that there may in fact be an association between degree of neonatal respiratory support and subsequent SDB; compared to infants with no respiratory support, the odds of SDB for children on oxygen or CPAP was 2.31 (0.23-23.30) and for infants with a history of intubation 3.74 (0.49-28.67).[26] It may be that in the larger SUPPORT population, such an association would be identified, and the SUPPORT trial would be an ideal population in which to address this question.

Both prematurity and SDB are associated with MRI changes.[11, 45-52] While the current literature does not support a link between neonatal ultrasound abnormalities and subsequent SDB, near-term MRI findings have not been assessed. In addition there is some evidence that SDB is associated with concurrent MRI changes, although many authors suggest that the SDB causes the neuroimaging changes. However, no one specific MRI abnormality is consistently reported. Using magnetic resonance spectroscopy (MRSI) Hallbower showed differences in hippocampal neuronal metabolism in children with SDB[11]. In addition, in adults, there is some mixed data suggesting a variety of detectable brain difference in the MRI's of patients with SDB, including lower fractional anisotrophy on diffusion tensor imaging, hippocampal atrophy, and other lesions.[48, 52] In addition, in the CCSHS, children born preterm were found to be more vulnerable to the neurocognitive effects of SDB; childhood neuroimaging was not done in this cohort.[8] It is unknown whether, in a preterm population, either near-term MRI abnormalities or concurrent MRI abnormalities in childhood are associated with SDB.

Methods: A validated 1-page questionnaire will be administered to the parent(s) at follow-up.[43, 44] Thus one-page questionnaire, the Sleep-Related Breathing Disorder (SRBD) scale of the Pediatric Sleep Questionnaire, has been shown to predict polysomnographic results with an accuracy useful for research, although it is not sufficiently accurate to substitute for polysomnography in individual patient care. The SRDB scale has three subscales, including a 4-item sleepiness scale, a 4-item snoring scale, and a 6-item inattention/hyperactivity scale. All questions responses are "yes" = 1, "no" = 0 and "don't know." An average question score $\geq$0.33 has been used to identify SDB.

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

We anticipate that the questionnaire will take ≤15 minutes to complete. *We propose that the questionnaire be administered by phone 1-6 weeks before the 6-7 year exam. This phone-call can also serve as a reminder call, and its proximity will allow correlation with other variables gathered at the 6-7 year exam, such as BMI.*

Study Design/ Definition of Population: This ancillary study will add a brief questionnaire to the planned 5-6 year follow-up assessment of the children *enrolled in the Breathing Outcomes* study 6-7 yr follow-up in the SUPPORT trial.

Inclusion criteria:

- *$24^{0/7}$-$27^{6/7}$ weeks gestation at birth*
- *Enrolled in SUPPORT*
- *Enrollment in the Breathing Outcomes follow-up*

Exclusion criteria

- *Major congenital malformations*
- *Failure to consent for Breathing Outcomes follow-up at 6-7 yrs*

This study will be linked to the Breathing Outcomes Follow-Up at 6-7 years of age. An analysis of differences between infants who presented to follow-up and those who were initially enrolled in the Breathing Outcomes study but did not follow-up will be performed. Key variables to assess differences will include gestational age, birthweight, race, sex, BPD, and the interventions to which they were initially randomized.

Description of Intervention: A validated, one-page, 22-item sleep-questionnaire will be administered to the parent(s).[43, 44] We estimate that it will take 10-15 minutes to complete, as described above.

Primary and Secondary Outcomes: The primary outcome will be SDB as defined by an average score of ≥0.33 on the SRBD scale. Secondary outcomes will be the actual score on the scale, and the distribution of answers to specific questions and domains within the questionnaire.

Sample Size: The SUPPORT trial aims to enroll 1310 infants born between $24^{0/7}$ and $27^{6/7}$ weeks gestation. *The Breathing Outcomes study is expected to follow-up 750 children at age 6-7 years.*

The following calculations are based on *750* infants, with a power of 0.8, and alpha of 0.05:

Estimate of Prevalence: The width of the confidence intervals for ascertaining the prevalence of SDB in the SUPPORT population is presented. At 8-11 years of age, between 4.3% and 7.4% of preterm children have SDB.[2] Most estimates of childhood SDB prevalence in the general population are 1-2%.[2, 36] The following table shows the 95% confidence intervals for a range of possible prevalence

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

rates for SDB in the SUPPORT trial. There would be sufficient power to find a significant difference between historical estimates of SDB prevalence in the general population and the SDB prevalence in the SUPPORT trial if the SUPPORT SDB prevalence is approximately 4% or higher.

Overall SDB prevalence	95% Confidence Interval
4% (n=*30*)	*2.6-5.4%*
6% (n=*45*)	*4.3-7.7%*
8% (n=*60*)	*6.1-9.9%*

Differences between groups: The detectable differences between groups are listed below, assuming a chi-squared test to detect differences in the prevalence of SDB. *For instance, if the baseline prevalence of SDB in the higher saturation arm is 6%, we would be able to detect a relative risk of 2.2 for lower saturations. Similarly, if the baseline rate of SDB in the CPAP arm is 8%, we would be able to detect a relative risk of 2.0 for randomization to intubation at delivery.*

Baseline Prevalence of SDB	Detectable Relative Risk
4%	*2.5*
6%	*2.2*
8%	*2.0*

We can also calculate the detectable difference between the groups using a t-test for difference in the mean SRDB scores in the two groups. Assuming a SRDB score standard deviation of 0.21,[44] we would be able to detect mean difference in scores of 0.04 between the two groups.

The following calculations are for an exploratory analysis of the association between MRI findings and SDB, based on an alpha of 0.05, a power of 0.8, and an N of 350, a conservative estimate of the infants enrolled in both the Breathing Outcomes and MRI follow-up studies:

The detectable relative risks are listed below, assuming a chi-squared test to detect differences in the prevalence of SDB in infants with MRI abnormalities. The range of the incidence of MRI abnormailites listed is based on recent reports of abnormalities in 75-95% of near-term MRIs.[45, 50] Moderate to severe findings have been reported in approximately 12%.[50]

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

Baseline Prevalence of MRI Abnormalities	***Baseline Incidence of SDB***		
	4%	***6%***	***8%***
10%	5.0	4.2	3.7
15%	4.2	3.6	3.2
75%	4.0	3.3	2.9
85%	4.2	3.6	3.2

Tests of continuous, as opposed to binary, differences in MRI findings would be more powerful. To assess differences in hippocampal volume in infants with and without SDB, we calculated the detectable difference in volumes for a t-test assuming an alpha of 0.05 and power of 0.8. For a range in SDB frequency between 10% and 4% in the total cohort, the detectable difference in volumes ranges from 0.49 to 0.77 of a standard deviation.

Available population: The proposed questionnaire will be administered to children participating in the SUPPORT study Breathing Outcomes follow-up at preschool age. The short questionnaire will only represent a minimal additional burden on the participants.

Recruitment: No additional recruitment resources would be needed for this ancillary study. *The phone-calls prior to the scheduled follow-up visit may aide retention and follow-up of infants enrolled in the Breathing Outcomes follow-up.*

Budget and Time Estimates:

Costs include research nurse time, data entry, and data analysis. We estimate:

- Approximately 20 minutes research nurse time per survey, as multiple phone calls may be necessary to reach a family.
    - 1/3 x 750 = 250 hrs.
    - At $35/hr this would equal 250 x $35 = $8,750
- Approximately 5 minutes per survey for data entry.
    - 1/12 x 750 = 62.5 hrs
- Approximately 12 hours of analysis time required.

SLEEP-RELATED BREATHING DISORDER SCALE

While sleeping, does your child…

	Yes	No	Not Sure
(1) Snore more than half the time?			
(2) Always snore?			
(3) Snore loudly?			
(4) Have "heavy" or "loud" breathing?			
(5) Have trouble breathing, or struggle to breathe?			

Have you ever…

	Yes	No	Not Sure
(6) Seen your child stop breathing during the night?			

Does your child…

	Yes	No	Not Sure
(7) Tend to breathe through the mouth during the day?			
(8) Have a dry mouth on waking up in the morning?			
(9) Occassionally wet the bed?			
(10) Wake up feeling unrefreshed in the morning?			
(11) Have a problem with sleepiness during the day?			

	Yes	No	Not Sure
(12) Has a teacher or other supervisor commented that your child appears sleepy during the day?			
(13) Is it hard to wake your child up in the morning?			
(14) Does your child wake up with headaches in the morning?			
(15) Did your child stop growing at a normal rate at any time since birth?			
(16) Is your child overweight?			

This child often…

	Yes	No	Not Sure
(17) Does not seem to listen when spoken to directly.			
(18) Has difficulty organizing tasks and activities.			
(19) Is easily distracted by extraneous stimuli.			
(20) Fidgets with hands or feet or squirms in seat.			
(21) Is "on the go" or act as if "driven by a motor."			
(22) Interrupts or intrudes on others (e.g. butts into conversations or games).			

Based on Chervin et al., Sleep Medicine, 2000.

RESPONSE TO CRITIQUE:
PROPOSAL FOR SUPPORT ANCILLARY STUDY:
PRE-SCHOOL SLEEP-DISORDERED BREATHING

Anna Maria Hibbs, MD, MSCE
Case Western Reserve University, Rainbow Babies and Children's Hospital
July 15, 2009

We thank the protocol committee for their comments, which we responded to in detail below. Changes in the protocol are marked in the text in italics.

Review –
This proposal has the following specific aims:
(1) Describe the prevalence of SDB symptoms in 5-6 year old children born VLBW.
(2) Assess differences between the saturation arms of the SUPPORT study in SDB prevalence at 5-6 years of age.
(3) Determine whether infants with a higher % of desats below target are more likely to have SDB at age 5-6 years
(4) Determine whether previously identified risk factors for SDB in older cohorts are also risk factors for SDB in 5-6 year old VLBW children.

The methodology is as follows:
Study Design/ Definition of Population: This ancillary study will add a brief questionnaire to the planned 5-6 year follow-up assessment of the children in the SUPPORT trial.
Description of Intervention: A validated, one-page, 22-item sleep-questionnaire will be administered to the parent(s) that takes 10-15 minutes to complete.

Comments
I believe that this proposal is reasonable and will take advantage of the 6 yr follow-up.
I have a number of concerns
1. The rate of SDB quoted is for 8-11 yr olds – what is that rate that can be determined at 6 yrs?

Determining the true prevalence in the VLBW population at this age is one of the specific aims because previous studies of SDB in infants born preterm have focused on preterm infants (all birth weights) at school-age and VLBW infants in young adulthood.[1, 2] While the rate of SDB in VLBW infants at 6 years of is not specifically known, we do not expect it to be meaningfully lower than at 8 years, because the peak prevalence of childhood SDB is thought to occur at 2-8 years of age,[3] and the VLBW population is likely to have more comorbidities than the general preterm population. Thus, in our power calculations the 8 year prevalence in the general preterm population represents a conservative estimate.

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

2. The questionnaire is brief – but there is a concern that the 6 yr exam etc may be long. Can this be administered during tracking at age 5 – will that change the outcomes? – this may enhance tracking and the questionnaire does not require a visit – could it be administered by phone?

We propose that it be administered by phone 1-6 weeks before the visit. Thus, the phone-call could both serve as a reminder/recruitment call, but also would be close enough to the study visit for anthropometric data such as BMI and Mallampati score to be relevant to the questionnaire results (see below).

3. Why have the investigators focused on the SpO2 values and not the need for intubation which can affect the airway. Thus CPAP or intubation may have a potential affect, and infants who required prolonged intubation may be at particular risk.

We agree that intubation and degree and duration of respiratory support will be important risk factors and/or potential confounders to assess as part of this study. In the Finnish study of young adults, there was no association between SDB and a history of mechanical ventilation. However, in the Cleveland Children's Sleep and Health Study (CCSHS), there was a non-significant suggestion that there may in fact be an association between degree of neonatal respiratory support and subsequent SDB; compared to infants with no respiratory support, the odds of SDB for children on oxygen or CPAP was 2.31 (0.23-23.30) and for infants with a history of intubation 3.74 (0.49-28.67). It may be that in the larger SUPPORT population, such an association would be identified, and certainly, just as with the SaO2 analysis, the SUPPORT trial would be an ideal population in which to address this question. The protocol has been modified to add this aim.

4. How do they propose to look at SpO2 values? Will they compare time below target, duration below 80% etc? This should be specified.

We propose using the percent of time with saturation less than 80%.

5. Is obesity/overweight a factor and will it be evaluated?

Obesity is a risk factor for SDB in children, although to a greater degree in post-pubertal patients. We propose using a BMI calculated at the study visit to adjust for obesity in the analyses if obesity is in fact associated with SDB in the SUPPORT population and in not equally distributed between randomized groups.

6. Could one add a quick oral examination to the 6 year exam – ie open your mouth and note the modified Mallampati score? (Mallampati, S. Ret al. A clinical sign to predict difficult tracheal intubation: a prospective study. Can Anaesth Soc J. 1985 Jul; 32(4):429-34.) This takes about 20 seconds or less.

We support the evaluation of the Mallampati score at the 6 year visit.

I would like to see the answers to the above queries before giving approval for this proposal.

Comments on proposal: "Pre-school Sleep-Disordered Breathing"

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

General: Dr. Hibbs has submitted a very interesting proposal that would investigate an inadequately studied and potentially extremely important problem. Extended follow-up of at least part of the SUPPORT cohort to 6-7 years would provide a unique opportunity to study SDB in extremely preterm infants, strengthened further by the fact that these children are within the context of a RCT of neonatal respiratory interventions. From the proposal description, it appears that only limited time (~15 minutes) would be required to administer the appropriate questionnaire for this ancillary. However, a major concern is that the 6-7 year neurodevelopmental follow-up visit is already quite long (in fact, we are in the process of trying to streamline the visit substantially), so the addition of any further questionnaires must be carefully considered. The size and description of the subcohort to which this ancillary would be attached should also be clarified.

Please see the response to (2) above regarding moving the SDB questionnaire to a reminder call prior to the 6 year visit. This strategy has the potential of limiting any additional burden during the visit, adding a contact with the family prior to the visit which could boost compliance with follow-up, and still being close enough to the visit to make use of anthropometric data and other variables gathered at the visit.

Specific comments and questions:

Abstract/Statement of Problem

- Description of targeted extended follow-up subcohort: From my reading of the proposal, it appears that an assumption is made that the *entire* SUPPORT trial cohort will be followed at 6-7 years. This is not the case. Currently, only the Neuroimaging and Neurodevelopmental Outcomes Secondary to SUPPORT subcohort has been approved for extended follow-up. That subcohort is *expected to include ~530-550 survivors to discharge* at the close of the trial. I hope (and dare I say expect) that the Breathing Outcomes Secondary to SUPPORT subcohort will also receive approval for extended follow-up as well. Dr. Tim Stevens *expects ~750 survivors to discharge in that subcohort by the close of the trial.* The proposal should be revised to reflect this information, particularly the power/detectable difference calculations.
    - Do the authors envision this ancillary to be more appropriately attached to the Neuroimaging and Neurodevelopmental Outcomes extended follow-up, or to Breathing Outcomes extended follow-up (assuming it is funded)? There could be benefits to either – as described further below.

  We propose that this ancillary be linked to the breathing outcomes study to maximize sample size and to benefit from the availability of other important respiratory confounders and risk factors, such as exposure to cigarette smoke. The sample size calculations in the protocol have been modified to reflect an expected sample size of 750. This would represent the largest cohort assessing SDB in children born preterm to date.

- Age at follow-up: Throughout the proposal, extended follow-up is described as "5-6 year follow-up". In fact, the approved Neuroimaging and Neurodevelopmental Outcomes extended follow-up and the proposed Breathing Outcomes extended follow-up will occur at **6-7 years**.

  The protocol has been revised to reflect follow-up at 6-7 years.

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

- Risk factors for SDB: Are any data available that would relate to hypotheses regarding specific *neonatal neuroimaging findings and risk for SDB?* Since the patients enrolled in the Neuroimaging and Neurodevelopmental Outcomes group will have specifically-timed cranial US and near term brain MRIs, all interpreted by central reader neuroradiologists, this would provide a unique chance to test such a hypothesis (assuming data support the proposal of such a hypothesis).

  For the reasons described above, we propose linking this ancillary study to the breathing outcomes study. However, secondary exploratory analyses could be performed on the subset of patients enrolled in both protocols. While the current literature does not support a link between neonatal ultrasound abnormalities and subsequent SDB, near-term MRI findings have not been assessed. In addition there is some evidence that SDB is associated with concurrent MRI changes, although many authors suggest that the SDB causes the neuroimaging changes. Hoewever, no one specific MRI abnormality is consistently reported. Using magnetic resonance spectroscopy (MRSI) Hallbower showed differences in hippocampal neuronal metabolism in children with SDB[4]. In addition, in adults, there is some mixed data suggesting a variety of detectable brain difference in the MRI's of patients with SDB, including lower fractional anisotrophy on diffusion tensor imaging, hippocampal atrophy, and other lesions.[5, 6] In addition, in the CCSHS, children born preterm were found to be more vulnerable to the neurocognitive effects of SDB; childhood neuroimaging was not done in this cohort.[7] Thus, an exploratory analysis of the subset of children enrolled in both follow-up protocols would address: (1) are neonatal MRI abnormalities associated with increased risk of childhood SDB (2) is SDB in childhood associated with concurrent MRI abnormalities? These exploratory analyses would require no new data collection. In the revised protocol, power calculations for this analysis are based on a conservative estimate of 350 infants enrolled in both the MRI follow-up and the Breathing Outcomes follow-up.

- *Hypotheses/Specific Aims*
- Patient description: It would probably be a good idea to be quite specific about the patients to be studied – in other words, instead of "children born VLBW", a more complete description based on SUPPORT entry criteria would be useful here.

  A brief summary of the SUPPORT entry criteria has been added to the revised protocol.

- 3rd hypothesis: Is there a specific oxygen saturation floor, or % of time spent below a proposed lower limit saturation that relates to this hypothesis?

  We propose to use time spent at a saturation <80%.

- 4th hypothesis: I do not believe the GDB NG02 captures information specifically on maternal *pre-eclampsia* (although maternal hypertension during and prior to pregnancy is queried), nor does it capture maternal smoking data. However, assuming the Breathing Outcomes extended follow-up is funded, there will be quite a bit of data regarding smoking exposure captured for that subcohort.

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

Maternal hypertension during pregnancy can be used in lieu of the pre-eclampsia variable. Smoking exposure at the 6-7 year visit is now proposed to measure smoking exposure.

- As noted above, hypotheses related to neuroimaging findings (particularly by MRI) would be interesting and appropriate to the Neuroimaging and Neurodevelopmental Outcomes cohort if supported by previous data.

  Please see response above.

- *Methods/Design/Statistical considerations*
- SRBD scale:
  - Is this questionnaire available/validated in Spanish?

    To our knowledge it is not available in Spanish. It is straight-forward and could be translated easily. A copy of the questions are appended to the end of the protocol.

  - The authors suggest that the questionnaire may be streamlined to remove attention deficit/hyperactivity component. We will be administering the attention/hyperactivity component of the Conners Rating Scale as well as the Strengths and Difficulties Questionnaire at 6-7 years, so we will have substantial information on attention and hyperactivity. It would be fantastic if we could save some time by cutting this domain of the SRBD questionnaire, and thus overlap could be avoided to reduce parental frustration. However, has the SRBD scale been validated *without* this component? If this domain is removed, could the proposed analyses be carried out as described (i.e., primary outcome defined by average score $\geq$0.33 on the SRBD scale)?

    We propose retaining the attention/hyperactivity component of the scale for the reasons mentioned and administering the scale by telephone as recommended above.

- Sample size: As noted previously, the entire SUPPORT cohort will not be followed to 6-7 years. The Neuroimaging and Neurodevelopmental Outcomes cohort is expected to have ~530-550 survivors to discharge by the close of SUPPORT. Estimating ~25% loss to follow-up, 400-420 would be seen in follow-up at 6-7 years. The SDB ancillary proposal estimates are based on the *total* SUPPORT cohort patient numbers (i.e., 1021 survivors to discharge, ~817 patients to extended follow-up). The Breathing Outcomes secondary cohort will be larger (~750 survivors to discharge by close of SUPPORT). The detectable difference calculations should be revised to reflect this information, and to determine if the true available sample size at 6-7 years would allow for detection of reasonable SDB difference from the general population estimates.

  We have revised our sample size estimates in the protocol to reflect the 750 infants expected in the breathing outcomes cohort.

The sample size they assume (n = 817) is clearly unattainable, because the neuroimaging follow up is predicated on a sample size of 350 and the pulmonary follow

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

up assumes a sample size of 384 at 6-7 years. So, they need to revisit those calculations and see if the study is still doable with the reduced sample size. Also, both these FU samples may not be representative of the trial population in general. The analysis plan needs to give some thought to that issue.

See above. In addition, we have added a comparison of characteristics of the infant followed versus not followed to the protocol.

Follow up is being done at 6-7 years, not 5-6 years. The neuroimaging cohort will have 350-450 children seen, not 817. A recent concept for breathing outcomes follow up was approved by the steering committee, so more children may be seen pending approvals.

The protocol has been revised to reflect follow-up at 6-7 years.

Is the rate of SDB higher in infants 24-27 6/7 weeks than in preterm infants in general? If so, less children will be needed for inclusion in the study. More detail in the analysis section is needed.

Data from the Cleveland and Finnish cohorts would suggest that there is NOT a higher rate in the smallest or most immature infants; simply being premature or VLBW is a risk factor with no apparent gradation by size or immaturity. The sample size calculations have been revised to target the breathing outcomes population as described above.

Is there a form or questionnaire that the committee can review to assess time of the interview?

A questionnaire is attached at the end of the protocol.

There is need for a budget for this study.

A budget is included.

Hi Wally,
Neither Marie nor I were able to interpret this statement. The non-enrolled infants were taken from eligible GDB infants, and not all of them even have Ante. Data. Can you
Ask the reviewer to try and clarify what they want, or if you understand, please help us ?
Thanks
wade

" I did have a question about the statement of infants who were enrolled in SUPPORT vs. the non-enrolled being significantly different. Especially about the discussion of antenatal steroid use—were authors able to characterize reason for not giving steroids? Were these all consented or some consented and some not? Would be interesting to see if there were more consents in the group who were consented despite enrollment or delivery in the window. "

Rose,
This is my draft, which I welcome you to edit. There are word limits you will notice.
Also attached is what I submitted for last year's iNO session for comparison.
I am attending a PPG review almost all day today, so after editing, I am fine for you to circulate to Neil and Wally (just cc me, so I know when we have the feedback and hopefully I can get this to Jim Kiley (Div Lung Diseases director) tomorrow.
The speakers (moderators) don't have to be committed yet.
If you think other literature should be here for the ATS committee to understand the field that are different than the 3 I suggested—feel free to replace.
Also, please fill in the pulse ox target ranges.

Session Information

Title Outcomes from the NHLBI-NICHD SUPPORT Trial: The Surfactant Positive Airway Pressure and Pulse Oximetry Trial in Extremely Low Birth Weight (ELBW) Infants

Target Audience *e.g. For providers of lung health? Specific Assemblies? Serving a specific patient group or multiple groups? Will your learners have clinical, research, administrative responsibilities? Do they need to learn about areas of medicine outside of their specialty?*

pulmonologists/neonatologists/pediatricians

Should attendees have specific expertise to benefit from this session? ☒ yes (clinical) ☐ no

Session Summary Include a brief summary of the course content, from the perspective of the learner, which runs no longer than 75 words.

Extremely low birth weight (ELBW) premature neonates suffer from higher~~increased~~ rates of ~~morbidity and~~ mortality and increasing rates of pulmonary morbidity compared to term newborns. Advances in therapy for the premature ~~have~~ suggested that mode of ventilation and oxygen toxicity increase risk of bronchopulmonary dysplasia (BPD) and retinopathy of prematurity (ROP). Results will be presented from the NHLBI / NICHD SUPPORT trial -- a prospective, randomized, factorial 2x2 design large multi-center trial that tested early CPAP versus standard~~and~~ mechanical ventilation management with a low or high pulse oximetry target on outcomes of BPD and ROP.

Have you served as faculty for a similar session before? ☒ yes ☐ no

Organization Name National Heart, Lung, and Blood Institute and National Institute of Child Health, NIH

Statement of Clinical/Scientific Importance Please state in 250 words or less the educational need for this session to be presented to ATS International Conference attendees. Identify the methods you used in determining this need by checking appropriate boxes below, rather than stating them in narrative.

1 What is that difference between current and optimal practice you wish to address with education? (This is called the professional practice gap.)
2 In order to narrow or eliminate the gap will your offering increase knowledge, competence (knowing how to do something), performance in work or practice or patient health/quality of life?

1) Current practice in neonatal intensive care units (NICU) is variable on the use of continuous positive airway pressure (CPAP) as an alternative to conventional ventilation, which permits early use of surfactant (a known beneficial treatment to prevent respiratory distress syndrome and BPD). In

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

addition, many clinicians in many NICUs have practices that permit oxygen saturation targets in the mid 80% range to reduce the incidence of ROP.

2) The SUPPORT trial was designed to close the gap on knowledge of the most effective strategies for the support of breathing and oxygenation in the very preterm infant. The effect of the alternative mode of ventilation (CPAP) without early use of surfactant combined with low (85-89%—) vs. high (91-95%—) pulse oximetry management has not previously been studied in a randomized fashion. Neonatal Network investigators will present the results of the SUPPORT trial and moderators will lead a discussion of the evidence, which could inform clinical practice for the ELBW infant. Primary outcomes of BPD and ROP will be presented.

Please cite 2 or 3 resources or references that could be reviewed by the Program Committee as evidence of need, if requested.

te Pas AB, Spaans VM, Rijken M, Morley CJ, Walther FJ Early nasal continuous positive airway pressure and low threshold for intubation in very preterm infants. *Acta Paediatr.* 2008 Aug;97(8):1049-54

What sources did you use to assess the needs of this target audience? Check all the sources that apply.

- ☐ Requests from ATS members/similar learners
- ☐ Previous course evaluation asking for suggestions
- ☐ Survey of target audience (requesting content)
- ☐ Self-assessment tests (e.g. pre-test, post test, case vignettes in surveys)
- ☐ Faculty perception
- ☐ Advice from authorities in the field
- ☐ This is a follow-up at a higher level to a previous course
- ☐ Review of literature
- ☒ New medical findings
- ☐ New guidelines
- ☐ Quality improvement data
- ☐ Formal needs assessment(s) by scholarly investigators
- ☐ Other

Can these data be applied to learners at the International Conference? ☒ yes ☐ no

Objectives Please provide three learning objectives below:

Your objectives should focus on closing the gap/solving the problem you identified under the Statement of Clinical/Scientific Importance. E.g. what will the learner be able to do/do better after attending your session? You may begin some of your objectives with the following: "will be able

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

to describe"; "will learn new findings about..."; "will appreciate the importance of...". At least one of your objectives should state how the learner will be able to apply new knowledge competence or performance/skill to his practice or work or improve quality of life or health of the patient. Eg. "will be better able to diagnose..."; "more appropriately refer..."; "refer earlier..."; "will have new strategies to manage the care of..."; "will integrate new treatment options in discussing xxx with the patient..."; "will be able to improve the quality of life/health status of his patients by xxx."

At the conclusion of this session, the learner will be able to:

1. To learn the impact of early CPAP on BPD and ROP in the SUPPORT trial
2. To learn the effect of high vs. low pulse oximetry targets on risk of BPD and ROP in the ELBW infant
3. Understand the interaction of mode of ventilation and target pulse oximetry on outcomes of BPD and ROP in ELBW infants.

Initial Disclosure of Faculty Conflicts of Interest

ATS International Conference requirements for disclosure and management of conflict of interest are based upon the ATS

Policy on Management of Conflict of Interest and **Policy on Tobacco Relationships.** Session proponents must complete the questions below as an initial disclosure. If the session is approved, session organizers, chairs and presenters will complete a detailed disclosure form and appropriate ATS oversight committees will review the disclosures as part of their oversight of sessions.

Please note:

- Many individuals have competing interests that may cause conflicts of interest. A COI depends on the situation and not on the character or actions of the individual. Examples of potential conflicts include personal financial relationships with commercial entities, or government or foundation funders, that are relevant to the session, including employment by a commercial entity; consultancy(ies); Board or Advisory Board; lecture fees; service as an expert witness; research grants; patents received or pending; royalties; and stock ownership or options (excluding mutual funds unless a sector fund concentrated in an industry[ies] relevant to the activity).
- The ATS "Policy on Tobacco Relationships" requires that individuals with a current tobacco industry relationship (or one in existence between now and the conclusion of the 2010 International Conference) not serve as a session planner (organizer), chair or presenter. (If limited to personal holdings of tobacco stocks or options, divestiture of such holdings a minimum of 30 days before the conference restores eligibility. See the policy for details.)
- Disclosure of a real or potential COI will not automatically invalidate a session proposal.

Session Proposer

1. Do you, as the proposer, have a personal financial interest(s) in a commercial entity (such as a pharmaceutical company or medical device manufacturer) that might be perceived as a real or potential conflict of interest (COI) relevant to the subject matter of this proposal?

   ☒No ☐Yes

2. Do you, as the proposer, have a personal financial interest(s) in a non-commercial entity (such as support from a government source or foundation or other non-profit source) that might be perceived as a real or potential conflict of interest (COI) relevant to the subject matter of this proposal?

   ☒No ☐Yes

3. Do you, as the proposer, have knowledge of your institution or employer having a significant financial relationship with a commercial entity that might be perceived as a real or potential conflict of interest (COI) relevant to the subject matter of this proposal?

   ☒No ☐Yes

4. Do you, as the proposer, have a relationship with a tobacco entity at present, or may within the twelve months prior to the conference?

   ☒No ☐Yes

Proposed Faculty

1. To your knowledge, does any other member of the proposed faculty (presenters) have a personal financial interest(s) in a commercial entity (such as a pharmaceutical company or medical device manufacturer) that might be perceived as a real or potential conflict of interest (COI) relevant to the subject matter of this proposal?

   ☒No ☐Yes

2. To your knowledge, does any other member of the proposed faculty (presenters) have a personal financial interest(s) in a non-commercial entity (such as support from a government source or foundation or other non-profit source) that might be perceived as a real or potential conflict of interest (COI) relevant to the subject matter of this proposal?

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

☒No ☐Yes

3. To your knowledge, does the institution or employer of any other member of the proposed faculty (presenters) have a significant financial relationship with a commercial entity that might be perceived as a real or potential conflict of interest (COI) relevant to the subject matter of this proposal?

☒No ☐Yes

4. To your knowledge, does any other member of the proposed faculty (presenters) have a relationship with a tobacco entity at present, or may within the twelve months prior to the conference?

☒No ☐Yes

Subject: ATS conference SUPPORT trial

Dear Neil and Wally,
Rose let me know that you were interested in submitting abstracts to PAS for the SUPPORT trial.

NHLBI has the opportunity to recommend for noon conferences (1 hour) the clinical trials that we (and in this case NICHD) support at the American Thoracic Society meeting each year.

I would like to work with you to develop a plan to present SUPPORT for the ATS attendees as well, using the NHLBI noon conference format as a mechanism for submission.

Please let me know if you might have time later today/tomorrow to discuss.
Attached is the format that ATS uses for submitting session proposals.

Subject: ATS conference SUPPORT trial

Dear Neil and Wally,
Rose let me know that you were interested in submitting abstracts to PAS for the SUPPORT trial.

NHLBI has the opportunity to recommend for noon conferences (1 hour) the clinical trials that we (and in this case NICHD) support at the American Thoracic Society meeting each year.

I would like to work with you to develop a plan to present SUPPORT for the ATS attendees as well, using the NHLBI noon conference format as a mechanism for submission.

Please let me know if you might have time later today/tomorrow to discuss.
Attached is the format that ATS uses for submitting session proposals.

ABSTRACT

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

Objective:

The purpose of t~~T~~his study was designed was to quantify the time ~~and~~ effort, and success involved in enrolling infants into the NICHD Neonatal Research Network (NRN) SUPPORT trial, ~~and to better predict the time required for recruitment into~~ a complex interventional trial requiring antenatal consent.

Design/Methods: I

~~A data form was designed to obtain~~ Information about eligible mothers who were available and approached at each center was collected, to determine who approached them, how often they were approached, the duration of each contact, whether consent was obtained and if the infant(s) was enrolled in the trial. ~~Infants born at Network centers who delivered in the SUPPORT (24 0/7 to 27 6/7 wk GA)~~Eligible, non-enrolled infants ~~were~~ entered into the NRN Generic Database were identified to allow comparison of enrolled and non-enrolled infants. ~~These data were used to identify infants who were eligible but not approached or enrolled.~~

Results

2828 women were identified at 18 NRN sites ~~collaborating units as being~~ to be at risk for premature delivery ~~at 24 to 27 6/7 wks GA~~ between October 2005 and February 2009. 2228 were approached for informed consent. The most common reasons for not approaching mothers included fetal abnormalities (x%), active labor (Y%) and language barriers (Z%). A study coordinator~~/research nurse made 75% of all approaches~~ approached 75% of all mothers . For 77% of those approached, ~~consent was attempted~~ < 3 visits were made to complete the consent process~~times~~. (~~Overall~~ mean 2.0 +/- 1.2). Estimated GA at time of screening was not different for those who consented versus those who did not. Seven percent of ~~those~~ mothers approached had~~were identified as having~~ been previously approached for another maternal study and 1% for another neonatal study. Of the 2228 mothers approached, 1217 (XX%) gave consent. Five hundred seventy-eight of those consented delivered 655

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

infants within the study window, and 535 of these delivered 610 infants that were enrolled. Forty-five consented infants born in the GA window ~~were not enrolled i.e., consent was given but~~ did not receive the study-prescribed interventions ~~was not undertaken~~. Only 19% of screened women delivered infants subsequently enrolled in the study. ~~There was a significant relationship between performing a neonatal consult and obtaining consent~~ Mothers who received a neonatal consult were more likely to give consent ($p<.0001$). Centers that were ~~also~~ NICHD Maternal Fetal Medicine network centers had ~~enrolled at~~ a higher consent rate and were more likely to obtain consent in ~~use~~ < 30 minutes ~~to obtain consent. A significantly higher proportion of infants who delivered in the study window but were not enrolled in SUPPORT had no exposure to antenatal steroids compared with infants who were enrolled.~~ Infants not enrolled in the SUPPORT trial had a lower rate of ANS use (3.8 vs. 15.7~~15.7 vs. 3.8~~% $p<.0001$) and this~~. The~~ difference was more significant in those not approached when compared to those approached~~in lack of antenatal steroid exposure was even greater for the infants of approached vs. non-approached women~~ (20.3 ~~3.4~~ vs. 3.4~~20.3~~%, $p<.0001$).

Conclusions:

In a complex interventional trial of preterm infants requiring antenatal consent, ≥~~more than~~ 5 women were identified as likely to deliver a baby in the GA window for each one who delivered an infant enrolled in the trial. Extrapolating these data ~~to the entire SUPPORT trial~~ suggests that over 2400 hours were spent screening greater than 6000 women to enroll 1317 infants in the SUPPORT trial. The differences between enrolled versus non-enrolled infants highlight the difficulties in attempting to recruit a representative population for prospective trials requiring antenatal consent.

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

Introduction:

~~The process of~~ Informed consent ~~was established to~~ ensures that subjects enrolled in research trials are~~were~~ appropriately informed as to the risks and benefits of the trial, came to the trial voluntarily, and represent~~ed~~ an accurate cross-section of all subjects who would potentially receive benefit from or undergo the risks of the studied intervention. Traditionally, this consent is obtained directly from the subject when they are in condition to understand and participate in the process. In conducting trials on infants who will receive an intervention at or near the time of birth, the process requires approaching families prior to delivery ~~to provide consent for their infant(s)~~.

Formatted: Normal, Indent: First line: 0"

Funding for clinical trials sponsored by federal agencies and industry is often based on a model of capitation where a site is paid based on the number of subjects enrolled and ~~some pre-calculated screening time~~some time allotted for screening. However, because prospective data comparing the number of families who are approached in the antenatal period to the number of infants who are

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

actually enrolled have not previously been available, the current model may not adequately account for time spent by study staff to screen, approach and enroll all eligible subjects.

~~Early enrollment~~ Early enrollment in the Surfactant Positive Airway Pressure and Pulse Oximetry Trial in Extremely Low Birth Weight Infants (SUPPORT) demonstrated that antenatal screening and consent were labor intensive and that actual patient enrollment numbers differed significantly from the screening and consent numbers~~rates~~. Thus, this secondary study was designed to evaluate the antenatal screening and consent process to determine the factors that contribute to successful enrollment of patients in a complex trial conducted by an experienced multi-center trials network.

Methods:

This is a prospective cohort study of the antenatal consenting practices of research personnel in the multi-center Neonatal Research Network (NRN) funded by the Eunice Kennedy Shriver National Institute of Child Health and Human Development (NICHD). Data for this study were collected during the second~~last~~ half of the NRN SUPPORT trial. The SUPPORT trial was designed to compare the use of early CPAP initiated in the delivery room to early intubation and surfactant given within the first hour of life, and to compare randomization to 2 different target SpO2 ranges during receipt of supplemental oxygen up to 36 weeks post menstrual age (PMA). Eligible infants were 24 0/7ths to 27 6/7ths weeks gestational age (GA) without known malformation for whom full postnatal treatment was planned~~expected~~.

Eligible subjects for the antenatal consent secondary study were those women who the Obstetrical/Perinatal staff felt were likely to deliver in the SUPPORT gestational age window. Clinical data were collected by trained research coordinators, and all analyses were performed at a central data coordinating center (DCC) (RTI International, Research Triangle Park, NC). Research staff collected~~self-reported~~ study data using a one page data collection form. If the parent(s) were not approached for consent, the reason they were not approached was recorded. If they were approached, the staff recorded the total number of times the parent(s) were approached, the number of such attempts which were made by the research coordinator/RN, and whether OB permission was obtained to approach for

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

antenatal consent. As a neonatal consult is often performed on this population, staff recorded whether a consult was performed, whether the consent was discussed during the consultation, and whether consent was obtained at the time of the consult. In some centers the Institutional Review Board required a consult be completed prior to consent, so this was also recorded. Women who were ~~approached for SUPPORT~~ approached were asked if they were approached for participation in any other studies ~~either~~ for themselves or their infants. Finally, the study staff was asked to estimate the time required to obtain a decision regarding consent.

Data were collected at each of the 18 NICHD NRN centers until fifty mothers had delivered within the window at the center. Data forms were keyed by the centers and transmitted electronically to the DCC. Infants born at Network centers who delivered in the SUPPORT window were entered into the NRN Generic Database (GDB) which, before 2008, collected delivery and demographic data on infants between 401 and 1500g inclusive birth weight who were inborn at NRN centers or admitted to the NICU within 14 days of age. Beginning in 2008, the database collected infants who were 1) inborn and between 401 grams and 1000 grams inclusive birth weight and/or 2) inborn and between 22 0/7 and 28 6/7 weeks (<29 weeks) inclusive gestational age. GDB data were used to evaluate whether infants enrolled in the SUPPORT trial represented the ~~entire~~ eligible NRN~~etwork~~ population.

To determine the representativeness of the population enrolled in the SUPPORT trial, data from the GDB were obtained for those infants born at NRN centers during the period of SUPPORT trial enrollment who qualified to participate in SUPPORT. Eligible but non-enrolled infants had information collected on ~~This information included whether~~ prenatal care ~~was obtained~~, the use of antenatal steroids and demographic data. These data were compared for infants who were or were not enrolled in SUPPORT to assess whether the trial had enrolled a representative sample of the available population. In addition, comparisons were made between eligible infants whose mothers were or were not approached for SUPPORT.

We performed bivariate statistical analyses using Chi-Square and Student's t-tests. All statistical analyses were performed using SAS version 9.1.3 (SAS Institute Inc., Cary, NC). A p value of less than 0.05 was considered statistically significant. This trial was approved by the Institutional Review Boards of all participating centers as well as that of RTI.

Results

Between October 2005 and February 2009, a total of 2828 women were identified at 18 NRN centers as being at risk for delivering a premature infant between 24 to 27 6/7 wks GA and were otherwise eligible for participation in the SUPPORT trial. Two ~~additional~~ NRN centers did not participate in the antenatal consent trial and 4 participating centers~~who did participate~~ did not identify 50 eligible women between the start of data collection for the antenatal consent study and the end of the SUPPORT trial. Four centers identified more than 50 women (mean 82) before they were ~~informed that they could~~ told to stop collecting data. All data collected by participating centers have been included in this analysis. A~~Results of an a~~nalysis using only the first 50 women from the centers that over-enrolled were not significantly different. S~~Data for s~~creening, enrollment and consent numbers by center are presented in Figure 1.

2228 women were approached for informed consent. The two most frequent reasons for not attempting to obtain a consent were early discharge and a lack of time prior to delivery (Table 2). Common choices within the "other" category in the table were early discharge, the inability of the mother to give consent, fetal abnormalities, and language barriers that made informed consent impossible. M~~Reasons m~~others were considered unable to give consent when in~~included being in~~ active labor, being too young, and having either a mental or physical health issue which precluded them being approached. A study coordinator or research RN made 75% of all approaches. For 77% of those women approached, consent was attempted < 3 times. (Overall mean 2.0 +/- 1.2). The frequency of approaches ranged from 1 (n=900) to 11 (n=2) times. The median time spent to obtain a decision regarding consent was less than 1 hour regardless of the decision. The estimated GA at time of screening was not

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

significantly different for those who consented versus those who did not. Of the 2228 mothers approached, 1217 (XX%) gave consent, 578 subsequently delivered 655 infants within the SUPPORT study window, and 535 delivered 610 infants who were enrolled (Figure 2). Forty-five consented infants born in the GA window (7%) were not enrolled, usually due to lack of staffing, equipment, or time. Only 19% of those mothers screened delivered infants who were subsequently enrolled in the study. A neonatal consult was performed in 70% of cases. ~~There was a significant relationship between performing a neonatal consult and obtaining~~ Mothers receiving a neonatal consult were more likely to consent (p <.0001), but consent was ~~only~~ obtained during the consult in only 12% ~~of the time~~. Centers that were ~~also~~ NICHD Maternal Fetal Medicine network centers enrolled at a higher rate (higher consent % or just larger numbers of infants approached?) and were more likely to require less than 30 minutes to obtain a consent decision. The median time spent to obtain a decision regarding consent for all centers was less than 1 hour regardless of the decision. (Did an MD making the first approach for consent have any influence on the success rate?)

Infants of non-approached and approached mothers were different in several important ways (Table 2). Infants of approached mothers were more likely to be non-Hispanic white (p<0.0001); ~~the mothers were more likely to be~~ older (p=0.0210) and to have a high school education (p<0.0001), medical insurance (p<0.0001), and at least one PNC visit (p<0.0001). (The N is large enough that p values of this magnitude for relatively small differences are not that surprising. Other than the clearly large and important difference in antenatal steroids, are any of these other differences thought to be clinically significant as well as statistically significant?) A significantly higher proportion of eligible non-enrolled infants not approached~~born in the study window whose mothers were not approached for SUPPORT~~ had no exposure to antenatal steroids compared with infants whose mothers were approached (20.3% vs 3.4%, p<.0001). Maternal gravidity and parity were not significantly different between these groups.

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

Infants who were enrolled in SUPPORT and those who were not enrolled were also significantly different. Non-enrolled infants had mothers who were significantly less likely to have insurance (p=0.0011) and to have received prenatal care (p=0.0039), and were over 4 times more likely to have gone without antenatal steroids (15.7% vs. 3.8%, p<0.0001) (Table 3).

Discussion:

To our knowledge this is the first neonatal study to evaluate the time and work required to approach and obtain antenatal consent from parents for the enrollment of their u~~premature~~nborn infants ~~who at the time of the consent were not yet born~~. Our results reveal that 5 families needed to be identified and screened for every one ~~that had an~~ infant successfully enrolled. Only 47% of women c~~from whom consent was obtained~~ onsented went on to deliver infants in the study window. Though the time needed to obtain consent was collected as a discrete variable, we found that the median was between 30 minutes and 1 hour. Multiplying these bounds by the number of women approached for each enrolled infant (3.7) yields a value for coordinator time required to obtain an enrolled infant at between 1.8 and 3.7 hours. This includes time spent approaching women who did not consent and consenting women who did not deliver in the window. It does not account for time spent screening women who were not approached for consent.

Morley et al reviewed parental willingness to participate in multiple trials in the neonatal period and found that most (74%) were willing to allow their baby to participate in multiple trials. [1] We had concerns that the burden of being approached for multiple trials, especially since 5 centers also belonged to a -maternal/fetal research network, would affect the enrollment in SUPPORT. We found that only 8% of women had been approached for another trial at the time of the SUPPORT consent discussion, probably because it was an antenatal consent and the window was early in gestation.

Because of the unique attributes of the NRN, we were able to obtain demographic data from the GDB for infants who were delivered in the SUPPORT window but were not enrolled in the study. Thus,

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

we were able to compare infants who were vs. were not enrolled and those whose mothers were vs. were not approached. These groups differed in a number of significant areas. Most importantly, infants born to women who were not approached for consent were almost 6 times more likely not to have been exposed to antenatal steroids, an intervention known to be associated with better short and longer term outcomes for preterm infants. [2] They were also more likely to be more immature and their mothers were significantly less likely to have insurance and to have received prenatal care.

In a review of NIH funded interventional randomized controlled trials, Charlson and Horwitz found that only half such trials kept any data on subjects who were eligible but not enrolled, and for those trials which c~~-did keep-~~ollected data only 27% of eligible non-enrolled subjects were a result of subject refusal.[3] The Consolidated Standards for Reporting of Trials (CONSORT) is a document created with the intent of standardizing items reported in trial publications, including a checklist for necessary items and a flow chart of participants.[4,5] The standards require the quantifying of eligible populations but make no such requirement for identifying the demographics of this group or its similarity to the enrolled or consented populations. Research from the California Department of Health Services reviewed the effect of the introduction of tandem Mass Spectrometry (MS/MS) to the California Newborn Screening program.[6] This involved another test on an already collected blood spot, for which it was decided informed consent was necessary. They found that the burden of adding informed consent to the screening process resulted in only 50% of infants being screened for the new test. Twenty one percent of participating hospitals did not offer the screening because of the burden of providing informed consent. It is very possible that failure rates for enrollment of infants in trials that require consent in the antenatal period is much higher than is currently believed. Following the CONSORT standards in all antenatal consent trials, both consented and waived, and obtaining basic demographic information for all eligible infants will help us understand whether similar reduction in enrollment

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

occurs when the burden of consent is added to these trials and whether the enrolled infants are representative of the true eligible population.

Blinding and randomization have always been the benchmarks for protecting trials from bias. Investigators have shown that trials in which allocation to a study group is well concealed more accurately reflect the true study effect than those not well concealed.[7] However, these controls only protect the trial from internal bias. Manning and Silverman have voiced concerns about selection bias, stating that a disproportionate number of vulnerable and deprived families are involved in clinical research.[8,9] Harth and Thong questioned parents who had volunteered in an asthma trial in Australia and concluded that volunteering parents were "significantly more socially disadvantaged and emotionally vulnerable." [10] In a study of recruitment and retention of premature infants into an early intervention program, Constantine et al found significant enrollment bias in this direction related to race, weight and site. [11] Zupancic et al. analyzed three postnatal trials in Canada, which has universal healthcare and other social benefits, and found no significant socio-economic difference between those who consented when compared with those who did not.[12] Mitchell and Kline, on the other hand, showed a significantly greater proportion of African-Americans, uninsured patients, and Medicaid recipients in the non-participant group in a minimal risk emergency department study.[13] Aagaard-Tillery and the NICHD Maternal Fetal Medicine (MFM) network found that blacks and Hispanics were significantly less likely to allow use of their genetic samples for future studies.[14]

Glassberg, Luce and Matthay analyzed the screening and enrollment of a trial of acute lung injury in two San Francisco hospitals, one an academic referral center and the other the public hospital for the city. [15] The percentage of screened infants enrolled was nearly 3 times higher in the academic center, a statistically significant difference ($p<.0001$). All of the centers in our trial were academic centers, but many included a relationship with a non-academic center. With the exception of Zupancic, which took place in a country with universal healthcare, all of these reports of selection bias point

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

toward the need to find a better method of enrolling truly representative populations for trials evaluating better practices.

O~~The bias in o~~ur analysis would suggest that under privileged subjects were less likely to participate. Because this trial enrolled subjects from all socio-economic groups at 18 academic centers with long-term randomized trial experience, it is not likely that the bias involved represents an intention to include or not include any group. The logical conclusion is that the many subjects who ended up excluded from this trial, despite the significant time and effort spent by the coordinators to include them, represent a failure of, or an innate problem with, the antenatal-consent process itself. Our observations, along with previous experience in a trial of a delivery room intervention[16], suggest that it is appropriate from an ethical perspective to allow trials that compare standard of care interventions to waive the consent process until after birth. This would ensure that the infants enrolled in such a trial do not differ significantly from the overall eligible population and insure the generalizability of the results.

Conclusion

Our prospective analysis of the process of antenatal consent enrollment in the NICHD Neonatal Research Network SUPPORT trial has shown that antenatal screening and consent are labor intensive, that actual patient enrollment numbers may be significantly lower than screening and consent rates, and that the population ~~studied~~enrolled as a result of antenatal consent -may not be representative of the total eligible population. In this complex interventional trial of preterm infants, nearly 5 women were identified as likely to deliver a baby in the window for every infant enrolled in the trial. Antenatal steroid use was significantly higher among infants enrolled in the SUPPORT study compared to those who were eligible but not enrolled, with a similar difference between infants born to approached and non-approached women. Along with quantifying the time and expense of antenatal consent, these observations point out the difficulties in attempting to recruit a representative population for prospective trials requiring antenatal consent and suggest that greater use of waiver of consent for trials that are low risk may be appropriate for future studies.

July 13, 2009

Dear Wally and Wade,

Thank you for the opportunity to review this manuscript, which provides very useful information regarding the antenatal consent process for clinical researchers. The effect of antenatal consent on the demographics of the enrolled infants is an important finding.

My overall comments are:

1. The majority of my comments are minor (wording suggestions included in manuscript with track changes).
2. I suggest placing each figure and table on a separate page with the title at the top.
3. The format for the references should be consistent and based on the specifications of the journal it will be submitted to.
4. Were there any center differences in overall consent or any of the other variables you investigated?
5. The fact that infants with less ANS exposure, prenatal care, and insurance were not enrolled is very important and strongly supports the need for waiver of consent for this type of study.
6. Who were the 2nd and 3rd most common people to approach for consent?
7. Did consent rates differ significantly based on who was obtaining consent?
8. Figure 1, "screeded" change to "screened".
9. Figure 2, instead of "night, weekend holiday" I suggest Study staff unavailable".
10. Table 3, headings could be "Enrolled infants" and "non-enrolled infants".

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

Subject: SUPPORT missing outcomes
Date: Friday, July 10, 2009 4:47:53 PM
Attachments: Infants with missing outcomes 07-10-09.xls

Attached is a list of the SUPPORT infants who are missing outcomes this week.

I am still working on a complete list of BPD queries. I have been working on them for over a week but they are not ready to go out yet and I only want to bother the centers once with this. I will keep you updated on my progress next week.

I also wanted to let you know that our final N for SUPPORT will be 1316 instead of 1317. One of the centers had apparently entered data for a stillborn baby; the twin was enrolled and both infants were mistakenly keyed for SUPPORT instead of just the one that was a live birth. Data for the stillbirth has now been removed from the SUPPORT and GDB files.

Thanks, and have a good weekend.

Subject: RE: BPD and ROP outcomes for SUPPORT

One more thing about BPD – less children had BPD by the physiologic definition in Michele's paper than by "oxygen use at 36 weeks" when first described, so, in fact, we may see a difference. I have attached the original paper (35% by oxygen definition, 25% by physiologic def)

Subject: RE: BPD and ROP outcomes for SUPPORT

Thanks, Neil. I understand what you are saying about the two definitions of BPD. I think it makes sense to look at both once we have the final data.

With respect to ROP, each infant with missing ROP is only listed in one of the 6 categories in the output I sent. There are a total of 137 infants with missing ROP, as seen on the first page. For the 113 infants who are older than 55 weeks PMA, their age and status at last exam, current PMA, and status of FU window are listed on the following pages.

Subject: RE: BPD and ROP outcomes for SUPPORT

Hi Marie
Thanks for the data. I know that the primary is the Physiologic definition. I am trying to get a handle on the gross results – and we will report the BPD by oxygen at 36 weeks as well as that is what most centers use – certainly all international ones. In addition by our own data we did not do the withdrawal as required and thus we are using a definition for these infants that no one else uses or understands. We will ultimately have to make a decision as to their diagnoses of BPD and they will not fit any current definition – ie on NC with RA flow because we believe that this represents some CPAP. We will report by the physiologic as we have indicated but we will need to see how concordant the findings are between these 2 definitions. I certainly do not intend to use any of the preliminary analyses and am OK to wait.
The issue will be whether we find a difference between the groups or not – if no differences are found using either – no problem, if the same differences between the groups using either – no problem – If the results differ by diagnosis of BPD – Big problem
Some of the BPD data in the form is difficult. I will look and send you my thoughts on the questionable ones – I agree with the Y and Ns
In the Table about the eye outcomes – are infants represented only once? That is can an infant have a Zone 2 at last exam and also be < 55 weeks??
I look forward to seeing a final data set. I will work on Tables and get them back to you.

Subject: RE: BPD and ROP outcomes for SUPPORT

Attached is the list of infants missing the ROP final outcome with the result of the last exam the infant had, the estimated PMA at the time of the last exam, the current estimated PMA and whether the FU window for the infant has yet to open, is open now, or is closed.

Neil, I know that you are eager to look at the BPD results, but I had a couple of questions/comments on your request. One is that the physiologic definition of BPD (or death) is the primary outcome listed in the protocol (see below), so I'm not sure why we would look at traditional BPD (oxygen at 36 weeks) first. Also, although we are only missing data on 5 infants, in the past several days I have come up with a list of queries for the centers (about 40 so far) where there are inconsistencies in BPD-related data that need to be cleared up, particularly between forms (NG07, PHY01, SUPP11, etc.). I am actually still working on these checks, as they are rather tedious, but I hope to be finished with them tomorrow so that the queries can go out to the centers. Because the queries will impact the data, Abhik suggests that we hold off on running the BPD outcome until they are resolved. In the meantime, if you want to put together shells for tables that you would like to have in the paper I can put together the programming to produce them.

One other thing that would be helpful is if you would take a look at the attached spreadsheet which has the current classification of physiologic BPD for infants who were eligible for the challenge but have comments explaining why the challenge did not take place. If you have any revisions to make to those classifications, please let me know. There are also a couple of infants with a '?' for BPD where I would appreciate your input.

Thanks,
Marie

From page 21 of the SUPPORT protocol:

5.3.1 Primary Outcome Measure

The primary outcome will be the percentage of infants surviving without BPD (using the Physiologic Definition) or severe ROP (threshold disease or the need for surgery).

Subject: RE: BPD and ROP outcomes for SUPPORT

Hi Marie
Please send me anything that we have for the BPD - a few missing infants will not change the final stats and I need to know what we found as soon as possible
I would start with BPD by oxygen at 36 weeks and we can later look at the Physiologic definition of BPD if the results differ
So for now if there are only 5 missing BPD infants let's do some of the study tables for demographics and the primary of survival without BPD, and the safety issues – death, air leaks DR compressions and Severe IVH
Lets also look at the number of ROP missing final diagnosis – I want to get a handle on how many are truly a problem of ascertainment.
Thanks for your help. I will not be sharing anything with anyone at this point until you feel we have a final data set for BPD and eventually for ROP which I know will be a bit more complex.
Thanks again
Neil

Subject: BPD and ROP outcomes for SUPPORT

Hi all,

As is it is almost 5:00 and tomorrow is a holiday, I just wanted to let you know that I am still working on the listing of who is missing the BPD and ROP outcomes for SUPPORT based on this week's data. It has taken me a little longer this week because I have carefully reviewed all of the BPD data and come up with a comprehensive list of both missing data and cases where we have inconsistent data. Unless Rose

objects, I will send her that list of queries in lieu of the usual missing data reminders for BPD this week. I will also send a breakdown of where we stand with respect to BPD and ROP, and the usual missing data reminders for ROP and NDI. You can expect those either later today or on Monday. FYI, we still have 5 infants for whom we are waiting on data for BPD (NG03 and NG07).

Have a great weekend!

Marie

Hi Alexis:

Yes, I will take this on as soon as I submit the cytokine paper which should happen in about two weeks. I would love to have you as a co-author as I know of your interest in this area.

Wally

Subject: ANS manuscript

Dr. Carlo-

Krisa mentioned that you and she spoke at the Network meeting about getting back to work on the antenatal steroids manuscript. I have attached comments (in green) in response to your thoughts (in red) from last August to serve as a platform for a conference call to discuss what the next steps might be to complete the project. I hope to be able to contribute ideas for analysis and perhaps help to finalize the manuscript to support my role as a contributing author for the project.

I am finishing up travel for the Preemie aEEG pilot in the next two weeks but could be available beginning the week of July 20th. Let me know what your schedule looks like or if you have an administrative person that I should work with to get this set up.

Thanks and have a good holiday weekend-
Alexis

ABSTRACT

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

Objective:

This study was designed to quantify the time and effort involved in enrolling infants into the NICHD Neonatal Research Network (NRN) SUPPORT trial and to better predict the time required for recruitment into a complex interventional trial requiring antenatal consent.

Design/Methods:

A data form was designed to obtain information about eligible mothers who were available and approached at each center, to determine who approached them, how often they were approached, the duration of each contact, whether consent was obtained and if the infant(s) was enrolled. Infants born at Network centers who delivered in the SUPPORT (24 0/7 to 27 6/7 wk GA) were entered into the NRN Generic Database. These data were used to identify infants who were eligible but not approached or enrolled.

Results

2828 women were identified at 18 collaborating units as being at risk for premature delivery at 24 to 27 6/7 wks GA between October 2005 and February 2009. 2228 were approached for informed consent. The most common reasons for not approaching mothers included fetal abnormalities, active labor and language barriers. A study coordinator/research nurse made 75% of all approaches. For 77% of those approached, consent was attempted < 3 times. (Overall mean 2.0 +/- 1.2). Estimated GA at time of screening was not different for those who consented versus those who did not. Seven percent of those approached were identified as having been approached for another maternal study and 1% for another neonatal study. Of the 2228 mothers approached, 1217 gave consent. Five hundred seventy-eight of those consented delivered 655 infants within the study window, and 535 of these delivered 610 infants that were enrolled. Forty-five consented infants born in the GA window were not enrolled i.e., consent was given but study-prescribed interventions was not undertaken . Only 19% of screened women delivered infants subsequently enrolled in the study. There was a significant relationship between performing a neonatal consult and obtaining consent ($p<.0001$). Centers that were also NICHD

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

Maternal Fetal Medicine network centers enrolled at a higher rate and were more likely to use < 30 minutes to obtain consent. A significantly higher proportion of infants who delivered in the study window but were not enrolled in SUPPORT had no exposure to antenatal steroids compared with infants who were enrolled. (15.7 vs. 3.8% p<.0001). The difference in lack of antenatal steroid exposure was even greater for the infants of approached vs. non-approached women (3.4 vs. 20.3%, p<.0001).

Conclusions:

In a complex interventional trial of preterm infants requiring antenatal consent, more than 5 women were identified as likely to deliver a baby in the window for each one who delivered an infant enrolled in the trial. Extrapolating these data to the entire SUPPORT trial suggests that over 2400 hours were spent screening greater than 6000 women to enroll 1317 infants in the trial. The differences between enrolled versus non-enrolled infants highlight the difficulties in attempting to recruit a representative population for prospective trials requiring antenatal consent.

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

Introduction:

The process of informed consent was established to ensure that subjects enrolled in research trials were appropriately informed as to the risks and benefits of the trial, came to the trial voluntarily, and represented an accurate cross-section of all subjects who would potentially receive benefit from or undergo the risks of the studied intervention. Traditionally, this consent is obtained directly from the subject when they are in condition to understand and participate in the process. In conducting trials on infants who will receive an intervention at or near the time of birth, the process requires approaching families prior to delivery to provide consent for their infant(s).

Funding for clinical trials sponsored by federal agencies and industry is often based on a model of capitation where a site is paid based on the number of subjects enrolled and some pre-calculated screening time. However, because prospective data comparing the number of families who are approached in the antenatal period to the number of infants who are actually enrolled have not previously been available, the current model may not adequately account for time spent by study staff to screen, approach and enroll all eligible subjects.

Early enrollment in the Surfactant Positive Airway Pressure and Pulse Oximetry Trial in Extremely Low Birth Weight Infants (SUPPORT) demonstrated that antenatal screening and consent were labor intensive and that actual patient enrollment numbers differed significantly from the screening and consent rates. Thus, this secondary study was designed to evaluate the antenatal screening and consent process to determine the factors that contribute to successful enrollment of patients in a complex trial conducted by an experienced multi-center trials network.

Methods:

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

This is a prospective cohort study of the antenatal consenting practices of research personnel in the multi-center Neonatal Research Network (NRN) funded by the Eunice Kennedy Shriver National Institute of Child Health and Human Development (NICHD). Data for this study were collected during the last half of the NRN SUPPORT trial. The SUPPORT trial was designed to compare the use of early CPAP initiated in the delivery room to early intubation and surfactant given within the first hour of life, and to compare randomization to 2 different target SpO2 ranges during receipt of supplemental oxygen up to 36 weeks post menstrual age (PMA). Eligible infants were 24 0/7ths to 27 6/7ths weeks gestational age (GA) without known malformation for whom full postnatal treatment was expected.

Eligible subjects for the antenatal consent secondary study were those women who the Obstetrical/Perinatal staff felt were likely to deliver in the SUPPORT gestational age window. Clinical data were collected by trained research coordinators, and all analyses were performed at a central data coordinating center (DCC) (RTI International, Research Triangle Park, NC). Research staff self-reported study data using a one page data collection form. If the parent(s) were not approached for consent, the reason they were not approached was recorded. If they were approached, the staff recorded the total number of times the parent(s) were approached, the number of such attempts which were made by the research coordinator/RN, and whether OB permission was obtained to approach for antenatal consent. As a neonatal consult is often performed on this population, staff recorded whether a consult was performed, whether the consent was discussed during the consultation, and whether consent was obtained at the time of the consult. In some centers the Institutional Review Board required a consult be completed prior to consent, so this was also recorded. Women who were approached for SUPPORT were asked if they were approached for participation in any other studies either for themselves or their infants. Finally, the study staff was asked to estimate the time required to obtain a decision regarding consent.

Data were collected at each of the 18 NICHD NRN centers until fifty mothers had delivered within the window at the center. Data forms were keyed by the centers and transmitted electronically

to the DCC. Infants born at Network centers who delivered in the SUPPORT window were entered into the NRN Generic Database (GDB) which, before 2008, collected delivery and demographic data on infants between 401 and 1500g inclusive birth weight who were inborn at NRN centers or admitted to the NICU within 14 days of age. Beginning in 2008, the database collected infants who were 1) inborn and between 401 grams and 1000 grams inclusive birth weight and/or 2) inborn and between 22 0/7 and 28 6/7 weeks (<29 weeks) inclusive gestational age. GDB data were used to evaluate whether infants enrolled in the SUPPORT trial represented the entire eligible Network population.

To determine the representativeness of the population enrolled in the SUPPORT trial, data from the GDB were obtained for those infants born at NRN centers during the period of SUPPORT trial enrollment who qualified to participate in SUPPORT. This information included whether prenatal care was obtained, the use of antenatal steroids and demographic data. These data were compared for infants who were or were not enrolled in SUPPORT to assess whether the trial had enrolled a representative sample of the available population. In addition, comparisons were made between eligible infants whose mothers were or were not approached for SUPPORT.

We performed bivariate statistical analyses using Chi-Square and Student's t-tests. All statistical analyses were performed using SAS version 9.1.3 (SAS Institute Inc., Cary, NC). A p value of less than 0.05 was considered statistically significant. This trial was approved by the Institutional Review Boards of all participating centers as well as that of RTI.

Results

Between October 2005 and February 2009, a total of 2828 women were identified at 18 NRN centers as being at risk for delivering a premature infant between 24 to 27 6/7 wks GA and otherwise eligible for participation in the SUPPORT trial. Two additional NRN centers did not participate in the antenatal consent trial and 4 who did participate did not identify 50 eligible women between the start of data collection for the antenatal consent study and the end of the SUPPORT trial. Four centers identified more than 50 women (mean 82) before they were informed that they could stop collecting data. All

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

data collected by participating centers have been included in this analysis. Results of an analysis using only the first 50 women from the centers that over-enrolled were not significantly different. Data for screening, enrollment and consent by center are presented in Figure 1.

2228 women were approached for informed consent. The two most frequent reasons for not attempting to obtain a consent were early discharge and a lack of time prior to delivery (Table 2). Common choices within the "other" category in the table were early discharge, the inability of the mother to give consent, fetal abnormalities, and language barriers that made informed consent impossible. Reasons mothers were considered unable to give consent included being in active labor, being too young, and having either a mental or physical health issue which precluded them being approached. A study coordinator or research RN made 75% of all approaches. For 77% of those women approached, consent was attempted < 3 times. (Overall mean 2.0 +/- 1.2). The frequency of approaches ranged from 1 (n=900) to 11 (n=2) times. The median time spent to obtain a decision regarding consent was less than 1 hour regardless of the decision. The estimated GA at time of screening was not significantly different for those who consented versus those who did not. Of the 2228 mothers approached, 1217 gave consent, 578 subsequently delivered 655 infants within the SUPPORT study window, and 535 delivered 610 infants who were enrolled (Figure 2). Forty-five consented infants born in the GA window (7%) were not enrolled, usually due to lack of staffing, equipment, or time. Only 19% of those mothers screened delivered infants who were subsequently enrolled in the study. A neonatal consult was performed in 70% of cases. There was a significant relationship between performing a neonatal consult and obtaining consent ($p < .0001$), but consent was only obtained during the consult 12% of the time. Centers that were also NICHD Maternal Fetal Medicine network centers enrolled at a higher rate and were more likely to require less than 30 minutes to obtain a consent decision. The median time spent to obtain a decision regarding consent for all centers was less than 1 hour regardless of the decision. (Did an MD making the first approach for consent have any influence on the success rate?)

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

Infants of non-approached and approached mothers were different in several important ways (Table 2). Infants of approached mothers were more likely to be non-Hispanic white ($p<0.0001$); the mothers were more likely to be older ($p=0.0210$) and to have a high school education ($p<0.0001$), medical insurance ($p<0.0001$), and at least one PNC visit ($p<0.0001$). (The N is large enough that p values of this magnitude for relatively small differences are not that surprising. Other than the clearly large and important difference in antenatal steroids, are any of these other differences thought to be clinically significant as well as statistically significant?) A significantly higher proportion of infants born in the study window whose mothers were not approached for SUPPORT had no exposure to antenatal steroids compared with infants whose mothers were approached (20.3% vs 3.4%, $p<.0001$). Maternal gravidity and parity were not significantly different between these groups.

Infants who were enrolled in SUPPORT and those who were not enrolled were also significantly different. Non-enrolled infants had mothers who were significantly less likely to have insurance ($p=0.0011$) and to have received prenatal care ($p=0.0039$), and were over 4 times more likely to have gone without antenatal steroids (15.7% vs. 3.8%, $p<0.0001$) (Table 3).

Discussion:

To our knowledge this is the first neonatal study to evaluate the time and work required to approach and obtain consent from parents for the enrollment of their premature infants who at the time of the consent were not yet born. Our results reveal that 5 families needed to be identified and screened for every one that had an infant successfully enrolled. Only 47% of women from whom consent was obtained went on to deliver infants in the study window. Though the time needed to obtain consent was collected as a discrete variable, we found that the median was between 30 minutes and 1 hour. Multiplying these bounds by the number of women approached for each enrolled infant (3.7) yields a value for coordinator time required to obtain an enrolled infant at between 1.8 and 3.7 hours. This includes time spent approaching women who did not consent and consenting women who

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

did not deliver in the window. It does not account for time spent screening women who were not approached for consent.

Morley et al reviewed parental willingness to participate in multiple trials in the neonatal period and found that most (74%) were willing to allow their baby to participate in multiple trials. [1] We had concerns that the burden of being approached for multiple trials, especially since 5 centers also belonged to a maternal/fetal research network, would affect the enrollment in SUPPORT. We found that only 8% of women had been approached for another trial at the time of the SUPPORT consent discussion, probably because it was an antenatal consent and the window was early in gestation.

Because of the unique attributes of the NRN, we were able to obtain demographic data from the GDB for infants who were delivered in the SUPPORT window but were not enrolled in the study. Thus, we were able to compare infants who were vs. were not enrolled and those whose mothers were vs. were not approached. These groups differed in a number of significant areas. Most importantly, infants born to women who were not approached for consent were almost 6 times more likely not to have been exposed to antenatal steroids, an intervention known to be associated with better short and longer term outcomes for preterm infants. [2] They were also more likely to be more immature and their mothers were significantly less likely to have insurance and to have received prenatal care.

In a review of NIH funded interventional randomized controlled trials, Charlson and Horwitz found that only half such trials kept any data on subjects who were eligible but not enrolled, and for those trials which did keep data only 27% of eligible non-enrolled subjects were a result of subject refusal.[3] The Consolidated Standards for Reporting of Trials (CONSORT) is a document created with the intent of standardizing items reported in trial publications, including a checklist for necessary items and a flow chart of participants.[4,5] The standards require the quantifying of eligible populations but make no such requirement for identifying the demographics of this group or its similarity to the enrolled or

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

consented populations. Research from the California Department of Health Services reviewed the effect of the introduction of tandem Mass Spectrometry (MS/MS) to the California Newborn Screening program.[6] This involved another test on an already collected blood spot, for which it was decided informed consent was necessary. They found that the burden of adding informed consent to the screening process resulted in only 50% of infants being screened for the new test. Twenty one percent of participating hospitals did not offer the screening because of the burden of providing informed consent. It is very possible that failure rates for enrollment of infants in trials that require consent in the antenatal period is much higher than is currently believed. Following the CONSORT standards in all antenatal consent trials, both consented and waived, and obtaining basic demographic information for all eligible infants will help us understand whether similar reduction in enrollment occurs when the burden of consent is added to these trials and whether the enrolled infants are representative of the true eligible population.

Blinding and randomization have always been the benchmarks for protecting trials from bias. Investigators have shown that trials in which allocation to a study group is well concealed more accurately reflect the true study effect than those not well concealed.[7] However, these controls only protect the trial from internal bias. Manning and Silverman have voiced concerns about selection bias, stating that a disproportionate number of vulnerable and deprived families are involved in clinical research.[8,9] Harth and Thong questioned parents who had volunteered in an asthma trial in Australia and concluded that volunteering parents were "significantly more socially disadvantaged and emotionally vulnerable." [10] In a study of recruitment and retention of premature infants into an early intervention program, Constantine et al found significant enrollment bias in this direction related to race, weight and site. [11] Zupancic et al. analyzed three postnatal trials in Canada, which has universal healthcare and other social benefits, and found no significant socio-economic difference between those who consented when compared with those who did not.[12] Mitchell and Kline, on the other hand, showed a significantly greater proportion of African-Americans, uninsured patients, and Medicaid

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

recipients in the non-participant group in a minimal risk emergency department study.[13] Aagaard-Tillery and the NICHD Maternal Fetal Medicine (MFM) network found that blacks and Hispanics were significantly less likely to allow use of their genetic samples for future studies.[14]

Glassberg, Luce and Matthay analyzed the screening and enrollment of a trial of acute lung injury in two San Francisco hospitals, one an academic referral center and the other the public hospital for the city. [15] The percentage of screened infants enrolled was nearly 3 times higher in the academic center, a statistically significant difference ($p<.0001$). All of the centers in our trial were academic centers, but many included a relationship with a non-academic center. With the exception of Zupancic, which took place in a country with universal healthcare, all of these reports of selection bias point toward the need to find a better method of enrolling truly representative populations for trials evaluating better practices.

The bias in our analysis would suggest that under privileged subjects were less likely to participate. Because this trial enrolled subjects from all socio-economic groups at 18 academic centers with long-term randomized trial experience, it is not likely that the bias involved represents an intention to include or not include any group. The logical conclusion is that the many subjects who ended up excluded from this trial, despite the significant time and effort spent by the coordinators to include them, represent a failure of, or an innate problem with, the antenatal-consent process itself. Our observations, along with previous experience in a trial of a delivery room intervention[16], suggest that it is appropriate from an ethical perspective to allow trials that compare standard of care interventions to waive the consent process until after birth. This would ensure that the infants enrolled in such a trial do not differ significantly from the overall eligible population and insure the generalizability of the results.

Conclusion

Our prospective analysis of the process of antenatal consent enrollment in the NICHD Neonatal Research Network SUPPORT trial has shown that antenatal screening and consent are labor intensive, that actual patient enrollment numbers may be significantly lower than screening and consent rates,

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

and that the population studied may not be representative of the total eligible population. In this complex interventional trial of preterm infants, nearly 5 women were identified as likely to deliver a baby in the window for every infant enrolled in the trial. Antenatal steroid use was significantly higher among infants enrolled in the SUPPORT study compared to those who were eligible but not enrolled, with a similar difference between infants born to approached and non-approached women. Along with quantifying the time and expense of antenatal consent, these observations point out the difficulties in attempting to recruit a representative population for prospective trials requiring antenatal consent and suggest that greater use of waiver of consent for trials that are low risk may be appropriate for future studies.

Dear Krisa,
Attached is a manuscript entitled "Antenatal Consent in a Large Multicenter Trial – At What Cost?" Would you be able to review the manuscript for the NICHD Neonatal Research Network by July 15 (two weeks)? There are no particular guidelines for the review except to look at study design, validity, clarity of results, and appropriateness of interpretation.

Please send the review to me. We will keep your name confidential.

Please let me know within 72 hours if you will be unable to do the review
Thanks,
Wally

ABSTRACT

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

Objective:

This study was designed to quantify the time and effort involved in enrolling infants into the NICHD Neonatal Research Network (NRN) SUPPORT trial and to better predict the time required for recruitment into a complex interventional trial requiring antenatal consent.

Design/Methods:

A data form was designed to obtain information about eligible mothers who were available and approached at each center, to determine who approached them, how often they were approached, the duration of each contact, whether consent was obtained and if the infant(s) was enrolled. Infants born at Network centers who delivered in the SUPPORT (24 0/7 to 27 6/7 wk GA) were entered into the NRN Generic Database. These data were used to identify infants who were eligible but not approached or enrolled.

Results

2828 women were identified at 18 collaborating units as being at risk for premature delivery at 24 to 27 6/7 wks GA between October 2005 and February 2009. 2228 were approached for informed consent. The most common reasons for not approaching mothers included fetal abnormalities, active labor and language barriers. A study coordinator/research nurse made 75% of all approaches. For 77% of those approached, consent was attempted < 3 times. (Overall mean 2.0 +/- 1.2). Estimated GA at time of screening was not different for those who consented versus those who did not. Seven percent of those approached were identified as having been approached for another maternal study and 1% for another neonatal study. Of the 2228 mothers approached, 1217 gave consent. Five hundred seventy-eight of those consented delivered 655 infants within the study window, and 535 of these delivered 610 infants that were enrolled. Forty-five consented infants born in the GA window were not enrolled i.e., consent was given but study-prescribed interventions was not undertaken . Only 19% of screened women delivered infants subsequently enrolled in the study. There was a significant relationship between performing a neonatal consult and obtaining consent ($p<.0001$). Centers that were also NICHD

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

Maternal Fetal Medicine network centers enrolled at a higher rate and were more likely to use < 30 minutes to obtain consent. A significantly higher proportion of infants who delivered in the study window but were not enrolled in SUPPORT had no exposure to antenatal steroids compared with infants who were enrolled. (15.7 vs. 3.8% p<.0001). The difference in lack of antenatal steroid exposure was even greater for the infants of approached vs. non-approached women (3.4 vs. 20.3%, p<.0001).

Conclusions:

In a complex interventional trial of preterm infants requiring antenatal consent, more than 5 women were identified as likely to deliver a baby in the window for each one who delivered an infant enrolled in the trial. Extrapolating these data to the entire SUPPORT trial suggests that over 2400 hours were spent screening greater than 6000 women to enroll 1317 infants in the trial. The differences between enrolled versus non-enrolled infants highlight the difficulties in attempting to recruit a representative population for prospective trials requiring antenatal consent.

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

Introduction:

The process of informed consent was established to ensure that subjects enrolled in research trials were appropriately informed as to the risks and benefits of the trial, came to the trial voluntarily, and represented an accurate cross-section of all subjects who would potentially receive benefit from or undergo the risks of the studied intervention. Traditionally, this consent is obtained directly from the subject when they are in condition to understand and participate in the process. In conducting trials on infants who will receive an intervention at or near the time of birth, the process requires approaching families prior to delivery to provide consent for their infant(s).

Funding for clinical trials sponsored by federal agencies and industry is often based on a model of capitation where a site is paid based on the number of subjects enrolled and some pre-calculated screening time. However, because prospective data comparing the number of families who are approached in the antenatal period to the number of infants who are actually enrolled have not previously been available, the current model may not adequately account for time spent by study staff to screen, approach and enroll all eligible subjects.

Early enrollment in the Surfactant Positive Airway Pressure and Pulse Oximetry Trial in Extremely Low Birth Weight Infants (SUPPORT) demonstrated that antenatal screening and consent were labor intensive and that actual patient enrollment numbers differed significantly from the screening and consent rates. Thus, this secondary study was designed to evaluate the antenatal screening and consent process to determine the factors that contribute to successful enrollment of patients in a complex trial conducted by an experienced multi-center trials network.

Methods:

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

This is a prospective cohort study of the antenatal consenting practices of research personnel in the multi-center Neonatal Research Network (NRN) funded by the Eunice Kennedy Shriver National Institute of Child Health and Human Development (NICHD). Data for this study were collected during the last half of the NRN SUPPORT trial. The SUPPORT trial was designed to compare the use of early CPAP initiated in the delivery room to early intubation and surfactant given within the first hour of life, and to compare randomization to 2 different target SpO2 ranges during receipt of supplemental oxygen up to 36 weeks post menstrual age (PMA). Eligible infants were 24 0/7ths to 27 6/7ths weeks gestational age (GA) without known malformation for whom full postnatal treatment was expected.

Eligible subjects for the antenatal consent secondary study were those women who the Obstetrical/Perinatal staff felt were likely to deliver in the SUPPORT gestational age window. Clinical data were collected by trained research coordinators, and all analyses were performed at a central data coordinating center (DCC) (RTI International, Research Triangle Park, NC). Research staff self-reported study data using a one page data collection form. If the parent(s) were not approached for consent, the reason they were not approached was recorded. If they were approached, the staff recorded the total number of times the parent(s) were approached, the number of such attempts which were made by the research coordinator/RN, and whether OB permission was obtained to approach for antenatal consent. As a neonatal consult is often performed on this population, staff recorded whether a consult was performed, whether the consent was discussed during the consultation, and whether consent was obtained at the time of the consult. In some centers the Institutional Review Board required a consult be completed prior to consent, so this was also recorded. Women who were approached for SUPPORT were asked if they were approached for participation in any other studies either for themselves or their infants. Finally, the study staff was asked to estimate the time required to obtain a decision regarding consent.

Data were collected at each of the 18 NICHD NRN centers until fifty mothers had delivered within the window at the center. Data forms were keyed by the centers and transmitted electronically

to the DCC. Infants born at Network centers who delivered in the SUPPORT window were entered into the NRN Generic Database (GDB) which, before 2008, collected delivery and demographic data on infants between 401 and 1500g inclusive birth weight who were inborn at NRN centers or admitted to the NICU within 14 days of age. Beginning in 2008, the database collected infants who were 1) inborn and between 401 grams and 1000 grams inclusive birth weight and/or 2) inborn and between 22 0/7 and 28 6/7 weeks (<29 weeks) inclusive gestational age. GDB data were used to evaluate whether infants enrolled in the SUPPORT trial represented the entire eligible Network population.

To determine the representativeness of the population enrolled in the SUPPORT trial, data from the GDB were obtained for those infants born at NRN centers during the period of SUPPORT trial enrollment who qualified to participate in SUPPORT. This information included whether prenatal care was obtained, the use of antenatal steroids and demographic data. These data were compared for infants who were or were not enrolled in SUPPORT to assess whether the trial had enrolled a representative sample of the available population. In addition, comparisons were made between eligible infants whose mothers were or were not approached for SUPPORT.

We performed bivariate statistical analyses using Chi-Square and Student's t-tests. All statistical analyses were performed using SAS version 9.1.3 (SAS Institute Inc., Cary, NC). A p value of less than 0.05 was considered statistically significant. This trial was approved by the Institutional Review Boards of all participating centers as well as that of RTI.

Results

Between October 2005 and February 2009, a total of 2828 women were identified at 18 NRN centers as being at risk for delivering a premature infant between 24 to 27 6/7 wks GA and otherwise eligible for participation in the SUPPORT trial. Two additional NRN centers did not participate in the antenatal consent trial and 4 who did participate did not identify 50 eligible women between the start of data collection for the antenatal consent study and the end of the SUPPORT trial. Four centers identified more than 50 women (mean 82) before they were informed that they could stop collecting data. All

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

data collected by participating centers have been included in this analysis. Results of an analysis using only the first 50 women from the centers that over-enrolled were not significantly different. Data for screening, enrollment and consent by center are presented in Figure 1.

2228 women were approached for informed consent. The two most frequent reasons for not attempting to obtain a consent were early discharge and a lack of time prior to delivery (Table 2). Common choices within the "other" category in the table were early discharge, the inability of the mother to give consent, fetal abnormalities, and language barriers that made informed consent impossible. Reasons mothers were considered unable to give consent included being in active labor, being too young, and having either a mental or physical health issue which precluded them being approached. A study coordinator or research RN made 75% of all approaches. For 77% of those women approached, consent was attempted < 3 times. (Overall mean 2.0 +/- 1.2). The frequency of approaches ranged from 1 (n=900) to 11 (n=2) times. The median time spent to obtain a decision regarding consent was less than 1 hour regardless of the decision. The estimated GA at time of screening was not significantly different for those who consented versus those who did not. Of the 2228 mothers approached, 1217 gave consent, 578 subsequently delivered 655 infants within the SUPPORT study window, and 535 delivered 610 infants who were enrolled (Figure 2). Forty-five consented infants born in the GA window (7%) were not enrolled, usually due to lack of staffing, equipment, or time. Only 19% of those mothers screened delivered infants who were subsequently enrolled in the study. A neonatal consult was performed in 70% of cases. There was a significant relationship between performing a neonatal consult and obtaining consent ($p < .0001$), but consent was only obtained during the consult 12% of the time. Centers that were also NICHD Maternal Fetal Medicine network centers enrolled at a higher rate and were more likely to require less than 30 minutes to obtain a consent decision. The median time spent to obtain a decision regarding consent for all centers was less than 1 hour regardless of the decision. (Did an MD making the first approach for consent have any influence on the success rate?)

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

Infants of non-approached and approached mothers were different in several important ways (Table 2). Infants of approached mothers were more likely to be non-Hispanic white ($p<0.0001$); the mothers were more likely to be older ($p=0.0210$) and to have a high school education ($p<0.0001$), medical insurance ($p<0.0001$), and at least one PNC visit ($p<0.0001$). (The N is large enough that p values of this magnitude for relatively small differences are not that surprising. Other than the clearly large and important difference in antenatal steroids, are any of these other differences thought to be clinically significant as well as statistically significant?) A significantly higher proportion of infants born in the study window whose mothers were not approached for SUPPORT had no exposure to antenatal steroids compared with infants whose mothers were approached (20.3% vs 3.4%, $p<.0001$). Maternal gravidity and parity were not significantly different between these groups.

Infants who were enrolled in SUPPORT and those who were not enrolled were also significantly different. Non-enrolled infants had mothers who were significantly less likely to have insurance ($p=0.0011$) and to have received prenatal care ($p=0.0039$), and were over 4 times more likely to have gone without antenatal steroids (15.7% vs. 3.8%, $p<0.0001$) (Table 3).

Discussion:

To our knowledge this is the first neonatal study to evaluate the time and work required to approach and obtain consent from parents for the enrollment of their premature infants who at the time of the consent were not yet born. Our results reveal that 5 families needed to be identified and screened for every one that had an infant successfully enrolled. Only 47% of women from whom consent was obtained went on to deliver infants in the study window. Though the time needed to obtain consent was collected as a discrete variable, we found that the median was between 30 minutes and 1 hour. Multiplying these bounds by the number of women approached for each enrolled infant (3.7) yields a value for coordinator time required to obtain an enrolled infant at between 1.8 and 3.7 hours. This includes time spent approaching women who did not consent and consenting women who

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

did not deliver in the window. It does not account for time spent screening women who were not approached for consent.

Morley et al reviewed parental willingness to participate in multiple trials in the neonatal period and found that most (74%) were willing to allow their baby to participate in multiple trials. [1] We had concerns that the burden of being approached for multiple trials, especially since 5 centers also belonged to a maternal/fetal research network, would affect the enrollment in SUPPORT. We found that only 8% of women had been approached for another trial at the time of the SUPPORT consent discussion, probably because it was an antenatal consent and the window was early in gestation.

Because of the unique attributes of the NRN, we were able to obtain demographic data from the GDB for infants who were delivered in the SUPPORT window but were not enrolled in the study. Thus, we were able to compare infants who were vs. were not enrolled and those whose mothers were vs. were not approached. These groups differed in a number of significant areas. Most importantly, infants born to women who were not approached for consent were almost 6 times more likely not to have been exposed to antenatal steroids, an intervention known to be associated with better short and longer term outcomes for preterm infants. [2] They were also more likely to be more immature and their mothers were significantly less likely to have insurance and to have received prenatal care.

In a review of NIH funded interventional randomized controlled trials, Charlson and Horwitz found that only half such trials kept any data on subjects who were eligible but not enrolled, and for those trials which did keep data only 27% of eligible non-enrolled subjects were a result of subject refusal.[3] The Consolidated Standards for Reporting of Trials (CONSORT) is a document created with the intent of standardizing items reported in trial publications, including a checklist for necessary items and a flow chart of participants.[4,5] The standards require the quantifying of eligible populations but make no such requirement for identifying the demographics of this group or its similarity to the enrolled or

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

consented populations. Research from the California Department of Health Services reviewed the effect of the introduction of tandem Mass Spectrometry (MS/MS) to the California Newborn Screening program.[6] This involved another test on an already collected blood spot, for which it was decided informed consent was necessary. They found that the burden of adding informed consent to the screening process resulted in only 50% of infants being screened for the new test. Twenty one percent of participating hospitals did not offer the screening because of the burden of providing informed consent. It is very possible that failure rates for enrollment of infants in trials that require consent in the antenatal period is much higher than is currently believed. Following the CONSORT standards in all antenatal consent trials, both consented and waived, and obtaining basic demographic information for all eligible infants will help us understand whether similar reduction in enrollment occurs when the burden of consent is added to these trials and whether the enrolled infants are representative of the true eligible population.

Blinding and randomization have always been the benchmarks for protecting trials from bias. Investigators have shown that trials in which allocation to a study group is well concealed more accurately reflect the true study effect than those not well concealed.[7] However, these controls only protect the trial from internal bias. Manning and Silverman have voiced concerns about selection bias, stating that a disproportionate number of vulnerable and deprived families are involved in clinical research.[8,9] Harth and Thong questioned parents who had volunteered in an asthma trial in Australia and concluded that volunteering parents were "significantly more socially disadvantaged and emotionally vulnerable." [10] In a study of recruitment and retention of premature infants into an early intervention program, Constantine et al found significant enrollment bias in this direction related to race, weight and site. [11] Zupancic et al. analyzed three postnatal trials in Canada, which has universal healthcare and other social benefits, and found no significant socio-economic difference between those who consented when compared with those who did not.[12] Mitchell and Kline, on the other hand, showed a significantly greater proportion of African-Americans, uninsured patients, and Medicaid

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

recipients in the non-participant group in a minimal risk emergency department study.[13] Aagaard-Tillery and the NICHD Maternal Fetal Medicine (MFM) network found that blacks and Hispanics were significantly less likely to allow use of their genetic samples for future studies.[14]

Glassberg, Luce and Matthay analyzed the screening and enrollment of a trial of acute lung injury in two San Francisco hospitals, one an academic referral center and the other the public hospital for the city. [15] The percentage of screened infants enrolled was nearly 3 times higher in the academic center, a statistically significant difference ($p<.0001$). All of the centers in our trial were academic centers, but many included a relationship with a non-academic center. With the exception of Zupancic, which took place in a country with universal healthcare, all of these reports of selection bias point toward the need to find a better method of enrolling truly representative populations for trials evaluating better practices.

The bias in our analysis would suggest that under privileged subjects were less likely to participate. Because this trial enrolled subjects from all socio-economic groups at 18 academic centers with long-term randomized trial experience, it is not likely that the bias involved represents an intention to include or not include any group. The logical conclusion is that the many subjects who ended up excluded from this trial, despite the significant time and effort spent by the coordinators to include them, represent a failure of, or an innate problem with, the antenatal-consent process itself. Our observations, along with previous experience in a trial of a delivery room intervention[16], suggest that it is appropriate from an ethical perspective to allow trials that compare standard of care interventions to waive the consent process until after birth. This would ensure that the infants enrolled in such a trial do not differ significantly from the overall eligible population and insure the generalizability of the results.

Conclusion

Our prospective analysis of the process of antenatal consent enrollment in the NICHD Neonatal Research Network SUPPORT trial has shown that antenatal screening and consent are labor intensive, that actual patient enrollment numbers may be significantly lower than screening and consent rates,

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

and that the population studied may not be representative of the total eligible population. In this complex interventional trial of preterm infants, nearly 5 women were identified as likely to deliver a baby in the window for every infant enrolled in the trial. Antenatal steroid use was significantly higher among infants enrolled in the SUPPORT study compared to those who were eligible but not enrolled, with a similar difference between infants born to approached and non-approached women. Along with quantifying the time and expense of antenatal consent, these observations point out the difficulties in attempting to recruit a representative population for prospective trials requiring antenatal consent and suggest that greater use of waiver of consent for trials that are low risk may be appropriate for future studies.

Hi Rose
I will present this email only for the steering committee. Can it be projected?

SUPPORT Update 6/19/2009

Total enrollment of 1317 was completed in February 2009. The primary outcomes of BPD/death and ROP/death are still unknown for 14 and 140 infants, respectively.

	ROP/death		
BPD/death	**Known**	**Unknown**	**Total**
Known	1172	131	1303
Unknown	5	9	14
Total	1177	140	1317

Infants with known outcomes for BPD/death and ROP/death

The last SUPPORT infant reached 36 weeks PMA in late May, so we should have complete data on the BPD outcome shortly. Historically, by 55 weeks PMA we have known ROP status for 100% of the infants with an adverse outcome and about 92% of the infants with a positive outcome. The last SUPPORT infant will reach 55 weeks PMA at the end of September.

To date, 778 (59%) of SUPPORT infants have a known outcome for NDI/death at 18-22 months adjusted age. The last follow up window will open in December 2010 and will close in April 2011.

Plans:

I will be starting to develop the manuscript
We are planning a visit to RTI and Wally will join us there at the end of August – hopefully when we can close the neonatal endpoints of ROP/BPD. We should have the BPD data within a few weeks
The plan is to develop 2 manuscripts –
CPAP vs Surfactant
High vs Lower SpO2

I suspect that we will be ready with the first within 2 months
And the second in 3 months
We would obviously submit as soon as they are ready – Probably NEJM

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

We need to complete the follow-up and we are well on the way with almost 60% of those outcomes available
The very first manuscript will be the consent manuscript which is now circulating to the authors. I have attached for your comments

Points for discussion:

1. Where should the data be presented??

It will be ready well ahead of PAS.
There will probably be new data for PAS – Secondaries etc

2. Need status reports for all secondaries
3. Continue to get all final infant data, especially ROP data, and complete follow-up

Safe travels
Neil

ABSTRACT

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

Objective:

This study was designed to quantify the time and effort involved in enrolling infants into the NICHD Neonatal Research Network (NRN) SUPPORT trial and to better predict the time required for recruitment into a complex interventional trial requiring antenatal consent.

Design/Methods:

A data form was designed to obtain information about eligible mothers who were available and approached at each center, to determine who approached them, how often they were approached, the duration of each contact, whether consent was obtained and if the infant(s) was enrolled. Infants born at Network centers who delivered in the SUPPORT window were entered into the NRN Generic Database. These data were used to identify infants who were eligible but not approached or enrolled.

Results

2828 women were identified at 18 collaborating units as being at risk for premature delivery at 24 to 27 6/7 wks GA between October 2005 and February 2009. 2228 were approached for informed consent. The most common reasons for not approaching mothers included fetal abnormalities, active labor and language barriers. A study coordinator/research nurse made 75% of all approaches. For 77% of those approached, consent was attempted < 3 times. (Overall mean 2.0 +/- 1.2). Estimated GA at time of screening was not different for those who consented versus those who did not. Seven percent of those approached were identified as having been approached for another maternal study and 1% for another neonatal study. Of the 2228 mothers approached, 1217 gave consent. Five hundred seventy-eight of those consented delivered 655 infants within the study window, and 535 of these delivered 610 infants that were enrolled. Forty-five consented infants born in the GA window were not enrolled. Only 19% of screened women delivered infants subsequently enrolled in the study. There was a significant relationship between performing a neonatal consult and obtaining consent ($p<.0001$). Centers that were also NICHD Maternal Fetal Medicine network centers enrolled at a higher rate and were more likely to use < 30 minutes to obtain consent. A significantly higher proportion of infants who delivered in the

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

study window but were not enrolled in SUPPORT had no exposure to antenatal steroids compared with infants who were enrolled. (15.7 vs. 3.8% p<.0001). The difference in lack of antenatal steroid exposure was even greater for the infants of approached vs. non-approached women (3.4 vs. 20.3%, p<.0001).

Conclusions:

In a complex interventional trial of preterm infants requiring antenatal consent, more than 5 women were identified as likely to deliver a baby in the window for each one who delivered an infant enrolled in the trial. Extrapolating these data to the entire SUPPORT trial suggests that over 2400 hours were spent screening greater than 6000 women to enroll 1317 infants in the trial. The differences between enrolled versus non-enrolled infants highlight the difficulties in attempting to recruit a representative population for prospective trials requiring antenatal consent.

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

Introduction:

The process of informed consent was established to ensure that subjects enrolled in research trials were appropriately informed as to the risks and benefits of the trial, came to the trial voluntarily, and represented an accurate cross-section of all subjects who would potentially receive benefit from or undergo the risks of the studied intervention. Traditionally, this consent is obtained directly from the subject when they are in condition to understand and participate in the process. In conducting trials on infants who will receive an intervention at or near the time of birth, the process requires approaching families prior to delivery to provide consent for their infant(s).

Funding for clinical trials sponsored by federal agencies and industry is often based on a model of capitation where a site is paid based on the number of subjects enrolled and some pre-calculated screening time. However, because prospective data comparing the number of families who are approached in the antenatal period to the number of infants who are actually enrolled have not previously been available, the current model may not adequately account for time spent by study staff to screen, approach and enroll all eligible subjects.

Early enrollment in the Surfactant Positive Airway Pressure and Pulse Oximetry Trial in Extremely Low Birth Weight Infants (SUPPORT) demonstrated that antenatal screening and consent were labor intensive and that actual patient enrollment numbers differed significantly from the screening and consent rates. Thus, this secondary study was designed to evaluate the antenatal screening and consent process to determine the factors that contribute to successful enrollment of patients in a complex trial conducted by an experienced multi-center trials network.

Methods:

This is a prospective cohort study of the antenatal consenting practices of research personnel in the multi-center Neonatal Research Network (NRN) funded by the Eunice Kennedy Shriver National Institute of Child Health and Human Development (NICHD). Data for this study were collected during the

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

last half of the NRN SUPPORT trial. The SUPPORT trial was designed to compare the use of early CPAP initiated in the delivery room to early intubation and surfactant given within the first hour of life, and to compare randomization to 2 different target SpO2 ranges during receipt of supplemental oxygen up to 36 weeks post menstrual age (PMA). Eligible infants were 24 0/7ths to 27 6/7ths weeks gestational age (GA) without known malformation for whom full postnatal treatment was expected.

Eligible subjects for the antenatal consent secondary study were those women who the Obstetrical/Perinatal staff felt were likely to deliver in the SUPPORT gestational age window. Clinical data were collected by trained research coordinators, and all analyses were performed at a central data coordinating center (DCC) (RTI International, Research Triangle Park, NC). Research staff self-reported study data using a one page data collection form. If the parent(s) were not approached for consent, the reason they were not approached was recorded. If they were approached, the staff recorded the total number of times the parent(s) were approached, the number of such attempts which were made by the research coordinator/RN, and whether OB permission was obtained to approach for antenatal consent. As a neonatal consult is often performed on this population, staff recorded whether a consult was performed, whether the consent was discussed during the consultation, and whether consent was obtained at the time of the consult. In some centers the Institutional Review Board required a consult be completed prior to consent, so this was also recorded. Women who were approached for SUPPORT were asked if they were approached for participation in any other studies either for themselves or their infants. Finally, the study staff was asked to estimate the time required to obtain a decision regarding consent.

Data were collected at each of the 18 NICHD NRN centers until fifty mothers had delivered within the window at the center. Data forms were keyed by the centers and transmitted electronically to the DCC. Infants born at Network centers who delivered in the SUPPORT window were entered into the NRN Generic Database (GDB) which, before 2008, collected delivery and demographic data on infants between 401 and 1500g inclusive birth weight who were inborn at NRN centers or admitted to

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

the NICU within 14 days of age. Beginning in 2008, the database collected infants who were 1) inborn and between 401 grams and 1000 grams inclusive birth weight and/or 2) inborn and between 22 0/7 and 28 6/7 weeks (<29 weeks) inclusive gestational age. GDB data were used to evaluate whether infants enrolled in the SUPPORT trial represented the entire eligible Network population.

To determine the representativeness of the population enrolled in the SUPPORT trial, data from the GDB were obtained for those infants born at NRN centers during the period of SUPPORT trial enrollment who qualified to participate in SUPPORT. This information included whether prenatal care was obtained, the use of antenatal steroids and demographic data. These data were compared for infants who were or were not enrolled in SUPPORT to assess whether the trial had enrolled a representative sample of the available population. In addition, comparisons were made between eligible infants whose mothers were or were not approached for SUPPORT.

We performed bivariate statistical analyses using Chi-Square and Student's t-tests. All statistical analyses were performed using SAS version 9.1.3 (SAS Institute Inc., Cary, NC). A p value of less than 0.05 was considered statistically significant. This trial was approved by the Institutional Review Boards of all participating centers as well as that of RTI.

Results

Between October 2005 and February 2009, a total of 2828 women were identified at 18 NRN centers as being at risk for delivering a premature infant between 24 to 27 6/7 wks GA and otherwise eligible for participation in the SUPPORT trial. Two additional NRN centers did not participate in the antenatal consent trial and 4 who did participate did not identify 50 eligible women between the start of data collection for the antenatal consent study and the end of the SUPPORT trial. Four centers identified more than 50 women (mean 82) before they were informed that they could stop collecting data. All data collected by participating centers have been included in this analysis. Results of an analysis using only the first 50 women from the centers that over-enrolled were not significantly different. Data for screening, enrollment and consent by center are presented in Figure 1.

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

2228 women were approached for informed consent. The two most frequent reasons for not attempting to obtain a consent were early discharge and a lack of time prior to delivery (Table 2). Common choices within the "other" category in the table were early discharge, the ability of the mother to give consent, fetal abnormalities, and language barriers that made informed consent impossible. Reasons mothers were considered unable to give consent included being in active labor, being too young, and having either a mental or physical health issue which precluded them being approached. A study coordinator or research RN made 75% of all approaches. For 77% of those women approached, consent was attempted < 3 times. (Overall mean 2.0 +/- 1.2). The frequency of approaches ranged from 1 (n=900) to 11 (n=2) times. The median time spent to obtain a decision regarding consent was less than 1 hour regardless of the decision. The estimated GA at time of screening was not significantly different for those who consented versus those who did not. Of the 2228 mothers approached, 1217 gave consent, 578 subsequently delivered 655 infants within the SUPPORT study window, and 535 delivered 610 infants who were enrolled (Figure 2). Forty-five consented infants born in the GA window (7%) were not enrolled, usually due to lack of staffing, equipment, or time. Only 19% of those mothers screened delivered infants who were subsequently enrolled in the study. A neonatal consult was performed in 70% of cases. There was a significant relationship between performing a neonatal consult and obtaining consent ($p < .0001$), but consent was only obtained during the consult 12% of the time. Centers that were also NICHD Maternal Fetal Medicine network centers enrolled at a higher rate and were more likely to require less than 30 minutes to obtain a consent decision. The median time spent to obtain a decision regarding consent for all centers was less than 1 hour regardless of the decision.

Infants of non-approached and approached mothers were different in several important ways as shown in Table 1. Infants of approached mothers were more likely to be non-Hispanic white ($p<0.0001$); the mothers were more likely to be older ($p=0.0210$) and to have a high school education ($p<0.0001$), medical insurance ($p<0.0001$), and at least one PNC visit ($p<0.0001$). A significantly higher proportion of infants born in the study window whose mothers were not approached for SUPPORT had no exposure to

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

antenatal steroids compared with infants whose mothers were approached (20.3% vs 3.4%, p<.0001). Maternal gravidity and parity were not significantly different between these groups.

Infants who were enrolled in SUPPORT and those who were not enrolled were also significantly different. Non-enrolled infants had mothers who were significantly less likely to have insurance (p=0.0011) and to have received prenatal care (p=0.0039), and were over 4 times more likely to have gone without antenatal steroids (15.7% vs. 3.8%, p<0.0001) (Table 2).

Discussion:

To our knowledge this is the first neonatal study to evaluate the time and work required to approach and obtain consent from parents for the enrollment of their premature infants who at the time of the consent were not yet born. Our results reveal that 5 families needed to be identified and screened for every one that had an infant successfully enrolled. Only 47% of women from whom consent was obtained went on to deliver infants in the study window. Though the time needed to obtain consent was collected as a discrete variable, we found that the median was between 30 minutes and 1 hour. Multiplying these bounds by the number of women approached for each enrolled infant (3.7) yields a value for coordinator time required to obtain an enrolled infant at between 1.8 and 3.7 hours. This includes time spent approaching women who did not consent and consenting women who did not deliver in the window. It does not account for time spent screening women who were not approached for consent.

Morley et al reviewed parental willingness to participate in multiple trials in the neonatal period and found that most (74%) were willing to allow their baby to participate in multiple trials. [1] We had concerns that the burden of being approached for multiple trials, especially since 5 centers belonged to a second maternal/fetal research network, would affect the enrollment in SUPPORT. We found that only 8% of women had been approached for another trial at the time of the SUPPORT consent discussion, probably because it was an antenatal consent and the window was early in gestation.

Because of the unique attributes of the NRN, we were able to obtain demographic data from the GDB for infants who were delivered in the SUPPORT window but were not enrolled in the study. Thus, we were able to compare infants who were vs. were not enrolled and those whose mothers were vs. were not approached. These groups differed in a number of significant areas. Most importantly, infants born to women who were not approached for consent were almost 6 times more likely not to have been exposed to antenatal steroids, an intervention known to be associated with better short and longer term outcomes for preterm infants. [2] They were also more likely to be more immature and their mothers were significantly less likely to have insurance and to have received prenatal care.

In a review of NIH funded interventional randomized controlled trials, Charlson and Horwitz found that only half such trials kept any data on subjects who were eligible but not enrolled, and for those trials which did keep data only 27% of eligible non-enrolled subjects were a result of subject refusal.[3] The Consolidated Standards for Reporting of Trials (CONSORT) is a document created with the intent of standardizing items reported in trial publications, including a checklist for necessary items and a flow chart of participants.[4,5] The standards require the quantifying of eligible populations but make no such requirement for identifying the demographics of this group or its similarity to the enrolled or consented populations. Research from the California Department of Health Services reviewed the effect of the introduction of tandem Mass Spectrometry (MS/MS) to the California Newborn Screening program.[6] This involved another test on an already collected blood spot, for which it was decided informed consent was necessary. They found that the burden of adding informed consent to the screening process resulted in only 50% of infants being screened for the new test. Twenty one percent of participating hospitals did not offer the screening because of the burden of providing informed consent. It is very possible that failure rates for enrollment of infants in trials that require consent in the antenatal period is much higher than is currently believed. Following the CONSORT standards in all antenatal consent trials, both consented and waived, and obtaining basic demographic information for

all eligible infants will help us understand whether similar reduction in enrollment occurs when the burden of consent is added to these trials and whether the enrolled infants are representative of the true eligible population.

Blinding and randomization have always been the benchmarks for protecting trials from bias. Investigators have shown that trials in which allocation to a study group is well concealed more accurately reflect the true study effect than those not well concealed.[7] However, these controls only protect the trial from internal bias. Manning and Silverman have voiced concerns about selection bias, stating that a disproportionate number of vulnerable and deprived families are involved in clinical research.[8,9] Harth and Thong questioned parents who had volunteered in an asthma trial in Australia and concluded that volunteering parents were "significantly more socially disadvantaged and emotionally vulnerable." [10] In a study of recruitment and retention of premature infants into an early intervention program, Constantine et al found significant enrollment bias in this direction related to race, weight and site. [11] Zupancic et al. analyzed three postnatal trials in Canada, which has universal healthcare and other social benefits, and found no significant socio-economic difference between those who consented when compared with those who did not.[12] Mitchell and Kline, on the other hand, showed a significantly greater proportion of African-Americans, uninsured patients, and Medicaid recipients in the non-participant group in a minimal risk emergency department study.[13] Aagaard-Tillery and the NICHD Maternal Fetal Medicine (MFM) network found that blacks and Hispanics were significantly less likely to allow use of their genetic samples for future studies.[14]

Glassberg, Luce and Matthay analyzed the screening and enrollment of a trial of acute lung injury in two San Francisco hospitals, one an academic referral center and the other the public hospital for the city. [15] The percentage of screened infants enrolled was nearly 3 times higher in the academic center, a statistically significant difference ($p<.0001$). All of the centers in our trial were academic centers, but many included a relationship with a non-academic center. With the exception of Zupancic, which took place in a country with universal healthcare, all of these reports of selection bias point

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

toward the need to find a better method of enrolling truly representative populations for trials evaluating better practices.

The bias in our analysis would suggest that under privileged subjects were less likely to participate. Because this trial enrolled subjects from all socio-economic groups at 18 academic centers with long-term randomized trial experience, it is not likely that the bias involved represents an intention to include or not include any group. The logical conclusion is that the many subjects who ended up excluded from this trial, despite the significant time and effort spent by the coordinators to include them, represent a failure of, or an innate problem with, the antenatal-consent process itself. Our observations, along with previous experience in a trial of a delivery room intervention[16], suggest that it is appropriate from an ethical perspective to allow trials that compare standard of care interventions to waive the consent process until after birth. This would ensure that the infants enrolled in such a trial do not differ significantly from the overall eligible population and insure the generalizability of the results.

Conclusion

Our prospective analysis of the process of antenatal consent enrollment in the NICHD Neonatal Research Network SUPPORT trial has shown that antenatal screening and consent are labor intensive, that actual patient enrollment numbers may be significantly lower than screening and consent rates, and that the population studied may not be representative of the total eligible population. In this complex interventional trial of preterm infants, nearly 5 women were identified as likely to deliver a baby in the window for every infant enrolled in the trial. Antenatal steroid use was significantly higher among infants enrolled in the SUPPORT study compared to those who were eligible but not enrolled, with a similar difference between infants born to approached and non-approached women. Along with quantifying the time and expense of antenatal consent, these observations point out the difficulties in attempting to recruit a representative population for prospective trials requiring antenatal consent and suggest that greater use of waiver of consent for trials that are low risk may be appropriate for future studies.

Hi all!

I had the opportunity to look over Wade's antenatal consent manuscript and have made comments on the attached version of that manuscript. Items in pink font are questions/suggestions; items in plum font are additions; while those items in red font are for deletion. I hope these thoughts are useful!

Roger

Hello Everyone
Congratulations on a job very well done!!
Marie has prepared the following summary for our meeting

SUPPORT Update 6/19/2009

Total enrollment of 1317 was completed in February 2009. The primary outcomes of BPD/death and ROP/death are still unknown for 14 and 140 infants, respectively.

	ROP/death		
BPD/death	**Known**	**Unknown**	**Total**
Known	1172	131	1303
Unknown	5	9	14
Total	1177	140	1317

Infants with known outcomes for BPD/death and ROP/death

The last SUPPORT infant reached 36 weeks PMA in late May, so we should have complete data on the BPD outcome shortly. Historically, by 55 weeks PMA we have

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

known ROP status for 100% of the infants with an adverse outcome and about 92% of the infants with a positive outcome. The last SUPPORT infant will reach 55 weeks PMA at the end of September.

To date, 778 (59%) of SUPPORT infants have a known outcome for NDI/death at 18-22 months adjusted age. The last follow up window will open in December 2010 and will close in April 2011.

She will try to get us some overall oximeter data if possible

I will be starting to develop the manuscript
We are planning a visit to RTI and Wally will join us there at the end of August – hopefully when we can close the neonatal endpoints of ROP/BPD. We should have the BPD data within a few weeks
The plan is to develop 2 manuscripts –
CPAP vs Surfactant
High vs Lower SpO2

I suspect that we will be ready with the first within 2 months
And the second in 3 months
We would obviously submit as soon as they are ready – Probably NEJM

We need to complete the follow-up and we are well on the way with almost 60% of those outcomes available
The very first manuscript will be the consent manuscript which is now circulating to the authors. I have attached for your comments

Points for discussion:

1. Where should the data be presented??

It will be ready well ahead of PAS.
There will probably be new data for PAS – Secondaries etc

2. Need status reports for all secondaries
3. Continue to get all final infant data, especially ROP data, and complete follow-up
4. Any additional bisuness??

Safe travels
Neil

Are these dates realistic; I realize neil is incredibly enthusiastic but we just had a call yesterday and data needs to be collated, made sure there are no glaring issues etc before it is worthwhile to get everyone on a call to discuss. AL

Hi Rose,

Is Carlo essential for this call? I was going to poll for the first 3 full weeks in June for this but I see Carlo is only available like 3 days out of those 3 weeks, so it may be difficult to come up with a time in mid-July if he has to be on the call.

Thanks,
Robin

Thanks Yvonne!

We will make sure you are on the SUPPORT Extended follow-up list. It is great having you on the conference calls.

Attached are the papers and the NIMH statement.

I am also attaching the 2 versions of the SDQ if you didn't get those. I think Gerry was referring to the fact that the "impact questions" at the end of the one version of the SDQ could not replace the Impact on the Family Questionnaire, but also that there really might not be much added by doing the Impact on the Family, particularly given that we do not have a specific question related to this instrument vis a vis the MRI secondary findings or the main trial.

Your points about timing of training and about Saturday visits are interesting and insightful. It would be interesting to see the days of the week that Hypothermia visits were done routinely. I know that half our visits were home visits!

Susan

> Susan,
>
> Good conference call, focused and moved right along.
>
> Could we extract the financial questions from the "Impact on the Family" questionnaire which would save time but give us potentially useful information? Did Gerry infer that if we had "extra" time there are additional psychometry items that he would like add?
>
> For the 1st Support cohort, we could do the training early (?August/September) for Stanford and UCSD out here; then do the training for everyone the next year (maybe also a bit earlier than usual given when the windows open.) We did this for Hypothermia as UCSD joined the Network at the end of the study so didn't participate in the training until the second year when our children's windows opened.

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

We have had to do several Saturday visits for Hypothermia due to space and personnel availability as well as reluctance of the family to take a day off from work, especially if they have to travel. It may take two days altogether to get here so the child is fresh in the AM. Maybe more of a problem for us as we have a small program with limited staff and space.

PS. Please add me to your Support FUP e-mail list so I can keep up to date. If you have a chance, and it is convenient, could you please forward the paper that Betty sent, the Chandler paper and the NIMH autism statement that were distributed?

Thanks.

Do you have any other comments or concerns?

Please turn over - there are a few more questions on the other side

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

Overall, do you think that your child has difficulties in one or more of the following areas: emotions, concentration, behavior or being able to get on with other people?

No	Yes-minor difficulties	Yes-definite difficulties	Yes-severe difficulties
☐	☐	☐	☐

If you have answered "Yes", please answer the following questions about these difficulties:

- How long have these difficulties been present?

Less than a month	1-5 months	6-12 months	Over a year
☐	☐	☐	☐

- Do the difficulties upset or distress your child?

Not at all	Only a little	Quite a lot	A great deal
☐	☐	☐	☐

Validation of the Social Communication Questionnaire in a Population Cohort of Children With Autism Spectrum Disorders

SUSIE CHANDLER, PH.D., TONY CHARMAN, PH.D., GILLIAN BAIRD, F.R.C.P.C.H., EMILY SIMONOFF, F.R.C.PSYCH., TOM LOUCAS, PH.D., DAVID MELDRUM, F.R.A.C.P., MIMI SCOTT, R.G.N., AND ANDREW PICKLES, PH.D.

ABSTRACT

Objective: To examine the properties of the Social Communication Questionnaire (SCQ) in a population cohort of children with autism spectrum disorders (ASDs) and in the general population. **Method:** SCQ data were collected from three samples: the Special Needs and Autism Project (SNAP) cohort of 9- to 10-year-old children with special educational needs with and without ASD and two similar but separate age groups of children from the general population ($n = 411$ and $n = 247$). Diagnostic assessments were completed on a stratified subsample ($n = 255$) of the special educational needs group. A sample-weighting procedure enabled us to estimate characteristics of the SCQ in the total ASD population. Diagnostic status of cases in the general population samples were extracted from child health records. **Results:** The SCQ showed strong discrimination between ASD and non-ASD cases (sensitivity 0.88, specificity 0.72) and between autism and nonautism cases (sensitivity 0.90, specificity 0.86). Findings were not affected by child IQ or parental education. In the general population samples between 4% and 5% of children scored above the ASD cutoff including 1.5% who scored above the autism cutoff. Although many of these high-scoring children had an ASD diagnosis, almost all (~90%) of them had a diagnosed neurodevelopmental disorder. **Conclusions:** This study confirms the utility of the SCQ as a first-level screen for ASD in at-risk samples of school-age children. *J. Am. Acad. Child Adolesc. Psychiatry* 2007;46(10):1324–1332. **Key Words:** autism, autism spectrum disorders, pervasive developmental disorders, screening, identification, SNAP cohort.

DOI: 10.1097/chi.0b013e31812f7d8d

The prevalence of autism spectrum disorders (ASDs), the common clinical term for the pervasive developmental disorders (PDDs) described in the psychiatric classification systems, *DSM-IV-TR* (American Psychiatric Association, 2000) and *ICD-10* (World Health Organization, 1993), is now recognized to be between 60 and 116/10,000, depending on the strictness with which the diagnostic criteria are applied (Baird et al., 2000, 2006; Chakrabarti and Fombonne, 2001, 2005; Green et al., 2005; Honda et al., 2005). Diagnosis requires careful history-taking and observation. However, screening questionnaires can help highlight a group requiring more in-depth diagnostic assessment. The Social Communication Questionnaire (SCQ; Rutter et al., 2003) is a recently developed screening tool for ASD based on the Autism Diagnostic Interview-Revised (ADI-R; Lord et al., 1994) and is increasingly widely used in clinical research and practice. In the

initial validation study the SCQ discriminated well between ASD and non-ASD cases with a sensitivity of 0.85 and a specificity of 0.75 (Berument et al., 1999). The ability of the SCQ to discriminate between ASD and non-ASD cases in two samples of 3- to 6-year-old children has recently been reported. Eaves et al. (2006a) found reduced sensitivity (0.71) in one study and reduced specificity (0.54) in a second study (Eaves et al., 2006b). Several other first-level screens for identifying potential cases of ASD have also been recently published, including the Social and Communication Disorders Checklist (Skuse et al., 2005) and the Social Responsiveness Scale (Constantino and Gruber, 2005).

The initial validation study of the SCQ (Berument et al., 1999) had a number of limitations on the generalizability of its findings; the study was carried out with subjects who had previously completed the ADI-R, thus introducing potential response bias; the subjects were recruited from a number of different research studies and clinical sources, and many participants with autism were adults, but the non-ASD participants were predominantly children.

The first aim of the present study was to examine the instrument properties of the SCQ in a population cohort of children with special educational needs (SENs) with and without ASD. The second aim was to explore how the SCQ performed in samples of similar-age children from the general population with whom the SCQ has not previously been used.

METHOD

The study was approved by the South East Multicentre Research Ethics Committee (REC) (00/01/50), East Sussex Local REC (04/Q/1905/6), and West Kent Local REC (153/8/02).

SCQ

Screening of all of the children was carried out using the SCQ (Rutter et al., 2003). The SCQ is a parent-report questionnaire asking about characteristic autistic behavior at the age of 4 to 5 years and currently. Total scores can range from 0 to 39. It is based on the ADI-R (Lord et al., 1994) and has established validity with the ADI-R and a diagnosis of autism (Berument et al., 1999).

Samples

SCQ data were collected from three different samples: Special Needs and Autism Project (SNAP) sample, a cohort of children at risk of ASD due either to having received a local clinical ASD diagnosis or having a Statement of Special Educational Needs (Baird et al., 2006; a Statement of Special Educational Needs is a legal document issued by the UK local educational authority when children require significant additional support in school due to any learning and/or behavioral problems); a group of children without a Statement of Special Educational Needs from mainstream schools (school sample); and a group of children living in one postal district in the same geographic area (general population sample).

At-Risk (SNAP) Cohort

As part of a prevalence study of ASD, of a total population cohort of 56,946 children born between July 1, 1990 and December 31, 1991 (Baird et al., 2006), all of those with a current clinical diagnosis of PDD (n = 255) or considered at risk of being an undetected case by virtue of having a Statement of Special Educational Needs (n = 1,515) were screened. A total of 1,066 completed SCQs were returned (mean return rate 60.2%), 31 families declined further participation, leaving 1,035 (return rate 58.5%) who returned the SCQ and opted in for further assessments (see Figure 1 for sample ascertainment). Mean (SD) age at screening in this SEN/ASD sample was 10.3 (0.4) years.

A stratified subsample (by coincidence also n = 255) received a comprehensive diagnostic assessment including standardized clinical observation (Autism Diagnostic Observation Schedule-Generic [ADOS-G]; Lord et al., 2000) and parent interview assessments of autistic symptoms (ADI-R; Lord et al., 1994), language and IQ, psychiatric comorbidities, and a medical examination. The age at which participants were assessed ranged from 9.8 to 14.5 years. The team used *ICD-10* research criteria to derive a clinical consensus diagnosis of childhood autism (n = 81) and other ASDs (n = 77; see Baird et al., 2006 for details). Of the 77 cases meeting criteria for other ASDs, three met *ICD-10* criteria for atypical autism due to late onset, three met *ICD-10* criteria for atypical autism due to an insufficient number of areas of abnormality, 61 met *ICD-10* criteria for atypical autism due to subthreshold symptomatology, 7 met *ICD-10* criteria for PDD unspecified due to lack of information (incomplete assessment, adopted children for whom early history was not available), and 3 met *ICD-10* criteria for overactive disorder associated with mental retardation and stereotyped movements. Ninety-seven children did not meet clinical consensus diagnosis for autism or other ASD. Ninety-six of the non-ASD children were assigned *ICD-10* diagnoses following assessment; these included intellectual disability (*DSM-IV-TR* mental retardation) and learning disabilities (n = 56), language delay (n = 12), hyperkinetic and/or conduct disorder (n = 14), and a variety of other medical, sensory, and developmental diagnoses (n = 15). One child had a Statement of Special Educational Needs but did not meet *ICD-10* criteria for any developmental disorder.

For 36 randomly selected cases, project consensus diagnoses were compared to those of eight internationally recognized experts using *ICD-10* criteria (usually two experts independently rated ADI-R, ADOS, psychometric findings, and a clinical vignette for each case. Quadratic weighted agreement between project consensus and expert autism/ASD/no ASD diagnostic categories was 93% with κ = .77 (see Baird et al., 2006 for details).

The following child characteristics relevant to identification by the screen were also collected: IQ, severity of autism symptoms measured by ADI-R and ADOS-G algorithm total scores and parent report of emotional and behavioral problems. A total count of *ICD-10* symptoms (0–12) was systematically completed as part of the diagnostic review process of every case. Adaptive behavior was assessed using the Vineland Adaptive Behavior Scales (VABS; Sparrow et al., 1984).

IQ was measured using the WISC-III-UK (Wechsler, 1992), Raven's Standard Progressive Matrices or Colored Progressive Matrices (Raven et al., 1990a,b), depending on the child's ability. For the 35 cases in which Standard Progressive Matrices or Colored Progressive Matrices but not WISC Full Scale IQs (FSIQs) were available, imputed FSIQs were obtained using the regression relationship of FSIQ to Standard Progressive Matrices/Colored Progressive Matrices IQ in each diagnostic group. For the 11 cases in which no direct cognitive testing was possible, 9 cases had Adaptive Behavior Composite on the VABS <20, and these cases were assigned an IQ score of 19 to reflect their profound level of mental retardation; two cases had no VABS data and were excluded from analysis involving IQ. The (weighted) mean (SD) FSIQ of the total ASD sample was 69.4 (24.1) and the range was 19 to 136. Fifty-five percent of all children with an ASD and 73% of the most narrowly defined autism cases had IQs <70 (Baird et al., 2006).

Parents completed the Strengths and Difficulties Questionnaire (SDQ; Goodman, 1997). Each subscale has five questions that are rated not true, somewhat true, and certainly true and scores 0 to 2 with higher scores indicating higher pathology. A total problem score derived from the hyperactivity/inattention, conduct problems, and emotional problems subscale scores was used in the present analysis. Information on parental education was also collected (defined by the highest academic qualification of either parent: 0 = none, 1 = O level [school-leaving examination given at age 16 years], 2 = NVQ [technical qualification], 3 = A level [school-leaving examination given at age 18 years], 4 = graduate, 5 = postgraduate).

Low-Risk School and General Population Samples

School Sample. The SCQ was sent to 936 families with children attending mainstream schools in a predominantly middle-income town in the southeastern United Kingdom. An initial mailing was followed by a reminder letter. A total of 411 SCQs were returned (rate 43.9%). The mean age of the children was 12.0 years (SD 0.3), and none had a Statement of Special Educational Needs.

General Population Sample. Children were recruited from one postal district in a mixed low- to middle-income town on the southern coast of the United Kingdom. Every family with a child born within an 18-month cohort was sent the SCQ (n = 582). An initial mailing was followed by a mailed reminder, then a telephone call, and then a home visit. A total of 247 SCQs were returned for a response rate of 42.4%. The mean age of children was 11.5 (SD 0.6). Sixteen (6.5%) parents reported their child as having a Statement of Special Educational Needs.

Statistical Analysis

SNAP Sample. Stratification of the ASD/SEN sample was based on whether a child had a locally recorded ASD diagnosis (yes/no) and four levels of SCQ score (low score [<8], moderately low score [8–14], moderately high score [15–21], high score [>22]; see Baird et al., 2006 and Figure 1 for details). Use of weights allowed all statistics such as proportions, means, group differences, and screen performance measures to be presented as target population estimates, taking account not only of the differences in sampling proportions according to SCQ score and local ASD diagnosis but also the differential response to the SCQ associated with a prior local ASD diagnosis, health district, and child's sex. Wald test statistics (adjusted t and F tests) and p values were calculated using the linearization version of the robust parameter covariance matrix as implemented by the svy procedures of Stata 9 (Stata Corporation, 2005). Confidence intervals for signal detection statistics such as sensitivity (Se), which compare the screen with a gold standard, or area under the curve (AUC), which compare the screen with another test measure, were obtained by bootstrap resampling. Statistics presented for the school and general population samples are unweighted because no stratified sampling was performed.

RESULTS

SNAP Sample

The mean SCQ score in the at-risk sample was 15.2 (SD 8.6) and the sample scored across nearly the full range of the possible scores (0–39). Figure 2 shows the distribution of SCQ scores for the 255 cases seen for a research diagnostic assessment, stacked by consensus diagnosis. The bimodal distribution is due to the stratified sample design of the prevalence study (see Baird et al., 2006 for details). Figure 2 shows exact frequencies; however, all of the subsequent analyses on the at-risk sample are weighted to take the sampling proportions and differential response into account.

The weighted mean (SD) SCQ scores for non-ASD, other ASD, and childhood autism cases were 10.8 (± 6.1), 19.6 (± 6.6), and 26.6 (± 4.4), respectively. SCQ scores were highly correlated with ASD symptom severity as measured by the ADI-R (total algorithm score: r = 0.79, p < .001) and consensus *ICD-10* symptom count (r = 0.71, p < .001), although more moderately correlated with ADOS total algorithm score (r = 0.42, p < .001). SCQ scores were moderately negatively correlated with VABS composite scores (r = −0.38,

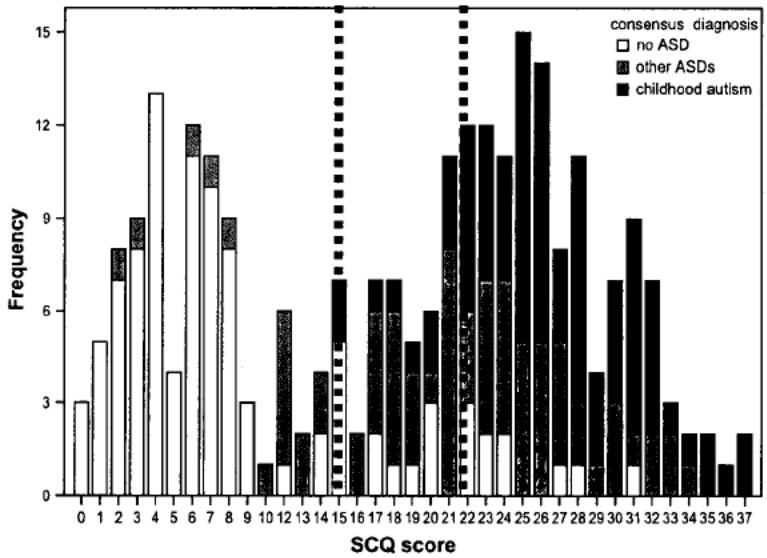

Fig. 2 Distribution of SCQ scores in the SNAP sample by consensus diagnosis (showing cutpoints of 15 and 22). SCQ = Social Communication Questionnaire; SNAP = Special Needs and Autism Project. ASD = autism spectrum disorder.

$p < .001$) but the correlation between SCQ scores and IQ was negligible ($r = -0.05$, not significant).

Discrimination Between ASD and Non-ASD Cases in the At-Risk SNAP Sample

A receiver operating characteristic (ROC) analysis was performed to assess the discriminant power of the SCQ in distinguishing ASDs (including autism) cases from non-ASD cases (Dunn, 2000; Hanley and McNeil, 1982). The AUC was 0.88 (95% CI 0.82–0.93), indicating strong discriminant ability. At the recommended cutoff of ≥15, Se was 0.88 (95% CI 0.78–0.95), specificity (Sp) 0.72 (95% CI 0.57–0.85), positive predictive value was 0.64 (95% CI 0.50–0.78), and negative predictive value was 0.91 (95% CI 0.82–0.97). To determine whether the ability of the SCQ to discriminate between ASD and non-ASD cases varied depending on IQ or parental education, the ROC analysis was repeated for cases with low (FSIQ <70) versus high (FSIQ >70) IQ and high (3–5) versus low (0–2) parental education. The AUC was ≥0.87 for both of these subgroup comparisons. Figure 3 shows the ROC curves for the SCQ (with labels for each score between 0 and 39) compared to that for the ADI-R total algorithm score. The AUC was high for both instruments.

Child and family characteristics relevant to being a true case missed by the cutpoint (i.e., being a false negative [FN] compared to being a true positive [TP]) and to being a noncase falsely identified by the cutpoint (i.e., being a false positive [FP] compared to being a true negative [TN]) were examined. We considered that

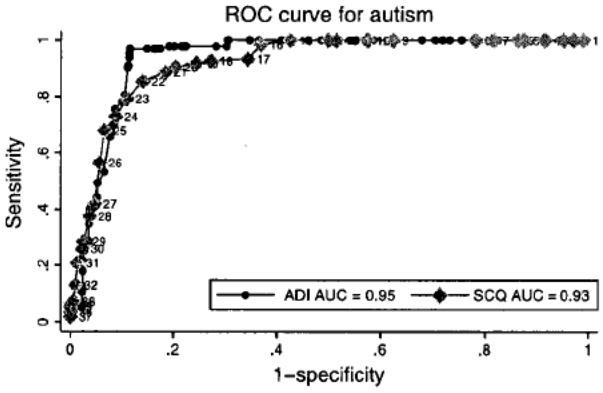

Fig. 3 ROC curve for SCQ and ADI-R discriminating ASD versus non-ASD (≥15). ROC = receiver operating characteristic; SCQ = Social Communication Questionnaire; ADI-R = Autism Diagnostic Interview-Revised; ASD = autism spectrum disorder.

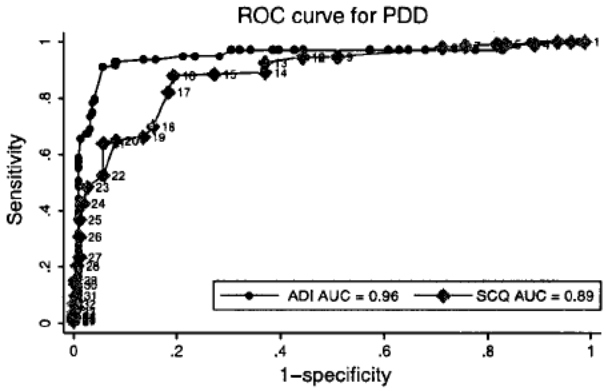

Fig. 4 ROC curve for SCQ and ADI-R discriminating autism vs. nonautism (≥22). ROC = receiver operating characteristic; SCQ = Social Communication Questionnaire; ADI-R = Autism Diagnostic Interview-Revised.

IQ, total algorithm scores on the ADI-R and ADOS-G, *ICD-10* total symptom count, and SDQ total problem score were relevant child characteristics and that parental education was a relevant background variable that may influence screen performance. FN cases had lower ADI-R algorithm scores (mean, 32.2, SE 3.13) than TP cases (40.9 ± 2.2; $Z = 1.98$; $p < .05$). FP cases had higher ADI-R algorithm scores (20.3 ± 1.6 versus 8.5 ± 1.0; $Z = 3.05$; $p < .01$) and higher SDQ total problem scores (14.3 ± 2.2 versus 12.1 ± 0.8; $Z = 2.06$; $p < .05$) than TN cases. FP cases did show a moderate level of ASD symptoms with a mean (SE) *ICD-10* total symptom score of 3.2 ± 0.5. Only 1.2% had received an ASD diagnosis from their local teams, however. All were given a non-ASD *ICD-10* diagnosis following assessment in the following (weighted) proportions: learning disability/mental retardation, 61.6%; language disorder, 7.7%; hyperkinetic disorder/ADHD, 25.2%; and other medical conditions, 5.5%.

Discrimination of Autism Cases From Nonautism Cases in the At-Risk SNAP Sample

A further ROC analysis, examining the ability of the SCQ to differentiate between childhood autism and nonchildhood autism cases (combining the other ASD and non-ASD groups) at the recommended cutoff of ≥22 also indicated strong discrimination (AUC 0.93, 95% CI 0.90–0.96), Se = 0.90 (95% CI 0.83–0.96); Sp = 0.86 (95% CI 0.80–0.90), PPV = 0.47 (95% CI 0.36–0.57), NPV = 0.98 (95% CI 0.97–0.99)). For the high and low IQ and high and low parental education subgroups, all of the AUCs were ≥0.90. Figure 4 shows

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

the ROC curves for the SCQ and ADI-R, and, once again, the AUC was high for both instruments.

There were no differences between FN and TP cases in IQ, ADI-R, and ADOS-G algorithm scores, *ICD-10* total symptom count, total SDQ score or parental education. FP cases (38.9 ± 2.0) had higher ADI-R algorithm scores than TNs (14.6 ± 1.5; $Z = 6.02$; $p < .001$). FP cases showed a high level of ASD symptoms with a mean (SE) *ICD-10* total symptom score of 5.6 ± 0.4, although the clinical consensus diagnosis for these cases was not childhood autism. Of the cases, 21.4% had received an ASD diagnosis from their local teams, although 70.6% of the FPs at the cutpoint of 22 received a consensus diagnosis of other ASDs. All of the other FPs were given a non-ASD *ICD-10* diagnosis following assessment in the following (weighted) proportions: learning disability/mental retardation, 52.0%; language disorder, 27.8%; hearing impairment, 4.7%; hyperkinetic disorder/ADHD, 14.3%; and other medical conditions, 1.1%.

Distribution of SCQ Scores in the Low-Risk School and General Population Samples

The distribution of SCQ scores in the school and general population samples was strongly negatively skewed. The mean (SD) SCQ score for the school sample was 4.1 ± 4.7, and the mean SCQ score for the general population cohort was 4.7 ± 5.0.

Of the school sample, 4.4% obtained an SCQ score of ≥15. The majority of these cases (16/18, 88.9%) had a neurodevelopmental diagnosis recorded (e.g., intellectual disability/mental retardation, language disorder, ADHD), although only 2 of 18 (11.1%) cases scoring at or above 15 had an ASD diagnosis recorded locally. Six cases scored at or above 22 and one (16.7%) of these had an ASD diagnosis recorded locally. The five others had other neurodevelopmental diagnoses recorded locally.

Of the general population sample, 5.3%scored at 15 or above on the SCQ. Twelve of 13 (92.3%) of these cases had a neurodevelopmental diagnosis recorded locally, of which seven of 13 (53.8%) of cases had an ASD diagnosis recorded locally. Four (of 13) cases scored at or above 22, and each had an ASD diagnosis recorded locally.

There was one FN among the school sample based on locally recorded diagnosis; this child has an SCQ score of 7. There were two FN cases within the general population cohort based on locally recorded diagnosis; one had an SCQ score of 9, and the other had an SCQ score of 12.

DISCUSSION

Properties of the SCQ in the At-Risk SNAP Sample

In the population-weighted SNAP sample, the SCQ discriminated well between children with and without ASD at the established cutpoint of ≥15. The Se (0.88) and Sp (0.72) were similar to that in the initial validation study (Se = 0.85; Sp = 0.75; Berument et al., 1999) and also compare well with those of two other recently published screening instruments for ASD (Social and Communication Disorders Checklist: Se = 0.90, Sp = 0.69 [Skuse et al., 2005]; Social Responsiveness Scale: Se = 0.85, Sp = 0.75 [Constantino and Gruber, 2005]). Two recent studies used the SCQ in younger samples of 3- to 6-year-old children and found reduced Se (0.71) in one study (Eaves et al., 2006a) and reduced Sp (0.54) in the other (Allen et al., in press; Eaves et al., 2006b). Reduced sensitivity in a younger sample is consistent with the fact that not all autism symptoms inquired about on the SCQ will necessarily have emerged in 3-year-olds with an ASD (e.g., repetitive routines or imaginative games with peers [Charman et al., 2005; Cox et al., 1999]) or not sufficiently for parents to have identified them as noteworthy.

When discriminating between autism and nonautism cases (including other ASDs) at the cutpoint of ≥22, the Se (0.90) and Sp (0.86) remained high. Note that these figures cannot be directly compared to those reported in Berument et al. (1999), who used the cutpoint of 22 to discriminate between autism and other ASD cases. We report data for the autism versus nonautism (including cases with an ASD but not a childhood autism diagnosis) discrimination because this is more likely to reflect the use of the screen in clinical practice, in which a sample will likely consist of children with autism, children with other ASDs, and children who do not have an ASD. The ROC analysis showed that the SCQ discriminated between ASD and non-ASD a little less well and autism and nonautism cases almost as well as the ADI-R. For diagnostic assessment, a full parental interview regarding current and past development and behavior and structured observation of the child, preferably including a

peer-group setting, are essential. Our study demonstrates that for some clinical and research purposes, the SCQ can be an efficient first-level screen to identify children with likely ASD or autism.

At both cutpoints Se and Sp in this sample were similar for the high and the low IQ subgroups and the correlation between SCQ score and IQ was close to zero. This contrasts with the study by Eaves et al. (2006b) who reported that SCQ scores were negatively correlated with IQ. Similarly, the ability of the SCQ to discriminate case and noncases at both cutpoints did not differ according to parental education. In different samples FP and FN cases may be explained by different child (e.g., IQ, age) and family (e.g., parental knowledge about autism, recognition of symptoms) factors, and these need to be considered alongside the score on the SCQ when assessing whether a child may likely have an ASD.

As would be expected, screen FNs scored lower than screen TPs, and, conversely, FPs scored higher than TNs on the ADI-R. The questions on the SCQ were closely modeled on ADI-R items, and on both instruments parents are the respondents. In contrast to Berument et al. (1999), in our study, parents completed the SCQ before completion of the ADI-R, thus reducing response bias on the screening instrument (note that the diagnosis relied on global clinical consensus using all information and not just the ADI-R). FPs at both cutpoints also had higher *ICD-10* total symptom scores than TNs (although lower scores than the screen TPs), reflecting the fact that many of the FP cases identified by the screen had subthreshold levels of ASD symptomatology. The majority of the FPs (~70%) at the cutpoint of 22 , which identifies likely autism cases, had a study consensus diagnosis of ASD; however, only one fifth had an ASD diagnosis from their local clinical team and few of the FPs at the cutpoint of 15 did so. One finding from the SNAP study was that only 58% of cases meeting consensus diagnosis of childhood autism had received an ASD from their local clinical teams, and this rate fell to 23% of cases meeting consensus diagnosis for other ASDs (Baird et al., 2006). Thus, reliance on local clinical diagnosis as the gold standard would underestimate the true proportion with ASDs among the FPs at the autism cutoff.

Screen FPs (in the ASD versus non-ASD comparison) scored higher than screen TNs on the total problem score of the SDQ. In response to questions on the SCQ that are meant to be measuring autism symptoms, some parents may rate their child's emotional, hyperactivity, or conduct difficulties. One previous study has reported high scores on the SCQ for children with mood and anxiety disorder in whom a clinical diagnosis of PDD had been excluded (Towbin et al., 2005). Among FPs at both cutpoints, we found children meeting criteria for other *ICD-10* neurodevelopmental conditions, including intellectual and learning disabilities, language delay, hearing impairment, hyperkinesis/ADHD, and physical disability.

Properties of the SCQ in the School and General Population Samples

Similar to the findings with other screens in normal populations (Constantino and Todd, 2003; Posserud et al., 2006; Skuse et al., 2005), the distribution of SCQ scores in the school and general population was heavily skewed to low scores, and the distribution of scores was continuous. In both samples approximately 4% to 5% of children scored above the SCQ cutoff of 15 that discriminated well between children with and without ASD. Not all of these screen-positive children had received a local clinical ASD diagnosis: 11% in the school sample and 54% in the general population sample. In both samples approximately 1.5% of children scored above the SCQ cutoff of 22 that discriminated well between children with and without childhood autism. Half of these children had received a local clinical ASD diagnosis. If the findings of local underidentification of ASD from the SNAP study apply to these samples from the same geographic region, then these may be underestimates of the number of actual cases of ASD in those who scored above the SCQ thresholds for ASD and autism (Baird et al., 2006). In both low-risk samples children with a locally recorded ASD diagnosis were rarely screen negative (<0.5% SCQ <15), although here local underidentification may underestimate the rate of FNs; however, almost all children with an SCQ score of ≥15 (~90%) had ASD or another neurodevelopmental disorder, including learning difficulties, language delay, and hyperkinetic disorder/ADHD.

Strengths

The strengths of the present study include the generalizability of the findings due to the population-weighting

procedure, the calculation of CIs around the instrument parameter estimates, the inclusion of children only in the sample (compared to Berument et al., 1999), and the inclusion of both low and high IQ children (compared to Skuse et al., 2005). The comprehensive diagnostic assessment and use of a clinical consensus decision-making process that was corroborated by independent expert rating (see Baird et al., 2006) are also strengths. We were also able to test whether child or family characteristics systematically related to FP and FN identification. Although the two studies investigating how the SCQ worked in unselected samples of same-age children were less methodologically rigorous, the present samples of children compare well in terms of size to other published studies (n = 411 and n = 247, respectively, compared with n = 118 in Skuse et al., 2005).

Limitations

One limitation of the present study is that the age of the at-risk sample at the time of screening (9–10 years) is older than would be required for first-level screening of young children, although it is still an age at which many children are referred for possible ASD. Other studies have begun to investigate how well the SCQ works in preschool children, so far with mixed findings (Eaves et al., 2006a,b). In comparison to our assessment of the SCQ in the at-risk SNAP sample, our attempt to screen children in the two low-risk samples had limitations: local clinical diagnoses of the unselected population subsamples were not confirmed by direct or standard clinical assessment and uptake was moderate only and subject to (unknown) bias, reducing the generalizability of these findings. They were considered worthwhile, however, because nothing was known about how the SCQ performs outside clinical samples, and screening instrument properties vary with sample prevalence and characteristics (Clark and Harrington, 1999).

Clinical Implications

This study confirms the utility of the SCQ as a first-level screen for ASD in at-risk samples of school-age children. In both our at-risk SNAP sample and in the low-risk general population samples, scoring above the cutoffs for autism (22) or ASD (15) was highly indicative that the child had childhood autism or ASD, respectively, or another neurodevelopmental condition that would warrant further assessment and likely support and intervention.

Disclosure: Prof. Baird has served as an occasional expert witness for the diagnosis of autism. Prof. Pickles receives royalties from SCQ and ADOS-G instruments. The other authors have no financial relationships to disclose.

Psychological Functioning and Coping Among Mothers of Children With Autism: A Population-Based Study Guillermo Montes, PhD, Jill S. Halterman, MD, MPH

Objectives: Studies suggest that having a child with autism has a negative impact on maternal psychological functioning, but no large-scale, population-based studies are available. The objectives of this study were to (1) describe the psychological functioning, physical and mental health, family communication, and parenting support of mothers of a child with autism compared with other mothers on a population basis and (2) assess the independent relationship between having a child with autism and these outcomes, controlling for the child's social skills and demographic background. *Methods:* Mothers of 61,772 children who were 4 to 17 years of age were surveyed by the National Survey of Children's Health, 2003. Autism was measured from an affirmative maternal response to the question, "Has a doctor or health professional ever told you your child has autism?" There were 364 children with autism in the sample. *Results:* Mothers of a child with autism were highly stressed and more likely to report poor or fair mental health than mothers in the general population, even after adjustment for the child's social skills and demographic background. However, mothers of a child with autism were more likely to report a close relationship and better coping with parenting tasks and less likely to report being angry with their child after adjustment for the child's social skills and demographic background. Having a child with autism was not associated with lower social support for parenting, an altered manner in which serious disagreements were discussed in the household, or increased violence in the household. *Conclusions:* Mothers of children with autism showed remarkable strengths in the parent–child relationship, social support, and stability of the household in the context of high stress and poorer mental health. **Pediatrics** 2007:119:e1040–e1046.

Efficacy of three screening instruments in the identification of autistic-spectrum disorders

TONY CHARMAN, GILLIAN BAIRD, EMILY SIMONOFF, TOM LOUCAS, SUSIE CHANDLER, DAVID MELDRUM and ANDREW PICKLES

Background Screening instruments for autistic-spectrum disorders have not been compared in the same sample.

Aims To compare the Social Communication Questionnaire (SCQ), the Social Responsiveness Scale (SRS) and the Children's Communication Checklist (CCC).

Method Screen and diagnostic assessments on 119 children between 9 and 13 years of age with special educational needs with and without autistic-spectrum disorders were weighted to estimate screen characteristics for a realistic target population.

Results The SCQ performed best (area under receiver operating characteristic curve (AUC)=0.90; sensitivity 0.86; specificity 0.78). The SRS had a lower AUC (0.77) with high sensitivity (0.78) and moderate specificity (0.67). The CCC had a high sensitivity but lower specificity (AUC=0.79; sensitivity 0.93; specificity 0.46). The AUC of the SRS and CCC was lower for children with IQ < 70. Behaviour problems reduced specificity for all three instruments.

Conclusions The SCQ, SRS and CCC showed strong to moderate ability to identify autistic-spectrum disorder in this at-risk sample of school-age children with special educational needs.

Declaration of interest Funding from the Wellcome Trust and the Department of Health, UK. A.P. receives royalties from the SCQ and ADOS–G.

There is considerable interest in screening instruments that identify children with possible autistic-spectrum disorders for a more in-depth diagnostic assessment. Recently developed screening instruments that have demonstrated promising properties in initial validation studies include the Social Communication Questionnaire (SCQ; sensitivity 0.85; specificity 0.75; Berument *et al*, 1999) and the Social Responsiveness Scale (SRS; 0.85; 0.75; Constantino & Gruber, 2005). The Children's Communication Checklist (CCC; Bishop, 1998) has a pragmatic composite sub-scale that has been shown to discriminate well between individuals with and without autism (Bishop & Baird, 2001). For clinicians and researchers a key consideration is which screen is most appropriate to their service or study. In the present study we directly compared the instrument properties of the SCQ, SRS and CCC in identifying individuals with autistic-spectrum disorders in a subsample of the Special Needs and Autism Project (SNAP; Baird *et al*, 2006) cohort of children 9–13 years of age with special educational needs with and without autistic-spectrum disorders.

METHOD

The study was approved by the South East Multicentre Research Ethics Committee (00/01/50). Patients gave informed consent.

Screening instruments

Social Communication Questionnaire

The SCQ (Rutter *et al*, 2003) is a 40-item parent-report questionnaire that asks about characteristic autistic behaviour. Each item is scored 0 or 1, with 1 being the score for endorsement of each symptom of autism. Total scores can range from 0 to 39 (the first item is a language screening question that is not included in the total score). The questionnaire is based on the Autism Diagnostic Interview – Revised (ADI–R; Lord *et al*, 1994) and it has established validity for a diagnosis of autism (Berument *et al*, 1999). Nineteen items rate current behaviour and 20 rate behaviour when the child was 4–5 years old. The recommended cut-off score for autistic-spectrum disorder or pervasive developmental disorder is $\geqslant 15$.

Social Responsiveness Scale

The SRS (Constantino & Gruber, 2005) is a 65-item rating scale asking about characteristic autistic behaviour over the previous 6 months. Each item is scored from 0 ('never true') to 3 ('almost always true'). Total scores can range from 0 to 195. For the present analysis a cut-off score of $\geqslant 75$ was chosen as that which best discriminates children with and without autistic-spectrum disorders (Constantino & Gruber, 2005: p. 38). Scores on the SRS discriminate between children with and without autistic-spectrum disorders and are strongly correlated with ADI–R domain scores (r=0.65–0.77; Constantino *et al*, 2003).

Children's Communication Checklist

Although not developed as a screen for autistic-spectrum disorders, the CCC (Bishop, 1998) is a 70-item rating scale that asks about language and communication impairments. Each item is scored 0 ('does not apply'), 1 ('applies somewhat'), 2 ('definitely applies') or missing value ('unable to judge'). Items ask about language and communication impairments and about competencies. The CCC is divided into 9 sub-scales: two sub-scales assess aspects of language structure (syntax and speech); two assess aspects of autistic behaviour (social relationships and interests); and five assess aspects of pragmatic communication (inappropriate initiation, coherence, stereotyped conversation, use of context, and rapport). These last five scales can be combined into a pragmatic composite. Bishop (1998) found that a CCC pragmatic composite score $\leqslant 132$ best identified children with pragmatic language impairment. This cut-off also discriminated well between children with and without autism in a clinical sample, but less well between individuals with Asperger syndrome or pervasive developmental disorder, not otherwise specified (PDD–NOS) and those with attention-deficit hyperactivity disorder (ADHD) (Bishop & Baird, 2001). The present study was started before the publication of the Children's Communication Checklist – Version 2 (CCC–2; Bishop, 2003).

SNAP cohort

As part of the larger SNAP study of the prevalence of autistic-spectrum disorders (Baird *et al*, 2006), within a total population cohort of 56 946 children born between 1 July 1990 and 31 December 1991 all those with a current clinical diagnosis of pervasive developmental disorder (n=255) or considered at risk of having the undetected disorder by virtue of having a statement of special educational needs (n=1515) were screened using the SCQ. (In the UK a statement of special educational needs is a legal document issued by a local educational authority when children require significant additional support in school because they have learning and/or behavioural problems.) A total of 1066 SCQs were returned completed (return rate 60.2%); 31 families declined further participation, leaving 1035 (return rate 58.5%) who returned the SCQ and opted in for further assessments. Mean age at SCQ screening in the whole SNAP sample was 10.3 years (s.d.=0.4 years). We have previously reported on the screening properties of the SCQ in the total sample, finding similar discrimination between individuals with autistic-spectrum disorders and those without as in the original validation sample (sensitivity 0.88; specificity 0.72; Chandler *et al*, 2007).

A stratified subsample (by coincidence, also n=255) received a comprehensive diagnostic assessment, including standardised clinical observation (the Autism Diagnostic Observation Schedule – Generic (ADOS–G; Lord *et al*, 2000)), parent-interview assessments of autistic symptoms (ADI–R; Lord, *et al*, 1994), language and IQ tests, evaluation of psychiatric comorbidities and a medical examination. The team used ICD–10 research diagnostic criteria (World Health Organization, 1993) to derive a clinical consensus diagnosis of childhood autism, other autistic-spectrum disorders or no autistic-spectrum disorder (for details see Baird *et al*, 2006). For 36 randomly selected children, project consensus diagnoses were compared with diagnoses by eight internationally recognised experts using ICD–10 criteria (two experts independently rated the ADI–R, ADOS–G, psychometric findings and a clinical vignette for each case). Agreement between the project consensus and expert diagnoses was 93% with (weighted) κ=0.77 (for details see Baird *et al*, 2006: Fig. 1).

We collated the following data for our subsample of 119 children: IQ; severity of symptoms of autism, measured by ADI–R and ADOS–G algorithm total scores; a total count of ICD–10 symptoms (0–12), systematically completed as part of the diagnostic review process of every case; parent and teacher reports of emotional and behavioural problems; and adaptive behaviour, assessed using the Vineland Adaptive Behavior Scales (VABS; Sparrow *et al*, 1984). The children's (n=118) IQ was measured using the Wechsler Intelligence Scale for Children (WISC–III–UK; Wechsler, 1992). The (weighted) mean full-scale IQ of the sample was 73.4 (s.e.=1.6) and the range was 40–136; 56% (weighted) of the children had an IQ<70. One child could not complete the WISC–III–UK and their IQ was derived using Raven's Standard Progressive Matrices (Raven *et al*, 1990).

Parents of a subsample of children (n=119) completed both the SRS and the CCC in addition to the SCQ. This afforded us the opportunity to directly compare the instrument properties of the three screens in the same sample.

Parents and teachers of these 119 children also completed the Strengths and Difficulties Questionnaire (SDQ; Goodman, 1997, 2001). Each sub-scale has five questions that are rated 'not true', 'somewhat true' and 'certainly true' and score 0–2, with higher scores indicating greater pathology. Four sub-scales (emotional problems, peer problems, conduct problems and hyperactivity) are summed to create a total problem score (range 0–40). We considered children whose teacher-rated ($\geq$16) and/or parent-rated ($\geq$17) total problem score fell around the 10% percentile in UK norms for SDQ scores (Meltzer *et al*, 2000) to have a high rate of behaviour problems.

Order of completion of assessments

In the larger study (Baird *et al*, 2006) the SCQ was used as the initial screening instrument to identify cases for in-depth diagnostic assessment; therefore the SCQ was completed for all children before the diagnostic assessments. For our subsample of 119 children with data on all three screening instruments the mean age at SCQ screening was 10.2 years (s.e.=0.4 years; range 9.5–11). The CCC was completed by parents immediately before the diagnostic assessment (mean age of children=12.0 years (s.e.=0.1 years; range 9.8–13.9). The SRS was completed at a mean age of 12.6 years (s.e.=0.4 years; range 11.8–13.2): for 50 children this was in advance of, and for 69 this was following, the diagnostic assessment and completion of the CCC. Scores on the three screening instruments were not consulted during the consensus clinical diagnostic process (for details see Baird *et al*, 2006). The 119 children in our subsample differed from the remainder of the cohort (n=136) in terms of IQ (mean=78.5 (s.e.=1.8) *v.* 67.4 (s.e.=2.2); ANOVA $F(1,251)=15.0$, $P<0.001$) but not symptom severity or parental education.

Statistical analysis

Stratification of the sample with autistic-spectrum disorders and special educational needs was based on whether or not a child had a locally recorded autistic-spectrum disorder diagnosis (yes/no) and one of four levels of SCQ score (low: <8; moderately low: 8–14; moderately high: 15–21; high: >22; for details see Baird *et al*, 2006: Fig. 1). Weighting allowed all statistics such as means, group differences and screen performance measures to be presented as target population estimates, taking account not only of the differences in sampling proportions according to SCQ score and local diagnosis of autistic-spectrum disorder, but also the differential response to the SCQ associated with a prior local autistic-spectrum disorder diagnosis, health district and child's gender. Wald test statistics (adjusted t- and F-tests) and P-values were calculated using the linearisation version of the robust parameter covariance matrix as implemented by the *svy* procedures of Stata 9 (Stata, 2005). A receiver-operator-characteristic (ROC) area-under-the-curve (AUC) analysis was performed to assess and compare the discriminant power of the screening instruments in distinguishing children with autistic-spectrum disorders (including autism) from those without (Hanley & McNeil, 1982; Dunn, 2000). Application of the weights ensured that this comparison was fair despite the SCQ-stratified sample design. Confidence intervals for weighted AUC estimates and tests were obtained using the bootstrap resampling ROC procedures of Stata 9, reverse coded in the case of the CCC.

RESULTS

Thirty-three children received a clinical consensus diagnosis of childhood autism; 37 a clinical consensus diagnosis of other

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

autistic-spectrum disorders (other-ASD); and 49 children did not meet clinical consensus diagnosis for autism or other autistic-spectrum disorders (non-ASD). Of the 37 children in the other-ASD group: 2 met ICD–10 criteria for atypical autism because of late onset; 2 met ICD–10 criteria for atypical autism because of an insufficient number of areas of abnormality; 29 met ICD–10 criteria for other pervasive developmental disorders because of sub-threshold symptomatology; 3 met ICD–10 criteria for 'pervasive developmental disorder, unspecified' because of lack of information (incomplete assessment, adopted children for whom early history was not available); and 1 met ICD–10 criteria for overactive disorder associated with mental retardation and stereotyped movements. Diagnoses for the 49 children in the non-ASD group included intellectual disability (DSM–IV–TR 'mental retardation'; American Psychiatric Association, 2000) and learning difficulties (n=27), language delay/disorder (n=7), hyperkinetic and/or conduct disorder (n=6) and a variety of other medical, sensory and developmental diagnoses (n=9).

Table 1 shows the weighted mean scores of the sample on the three screens by consensus diagnostic group. As would be expected, individuals in the childhood autism group scored higher than those in the other-ASD and non-ASD groups on the SCQ and SRS and lower on the (reverse-scored) CCC pragmatic composite. Similarly, the children in the other-ASD group scored higher than those in the non-ASD group on the SCQ and SRS and lower on the CCC pragmatic composite. For the SCQ all three group-by-group comparisons were significant (other-ASD $v.$ non-ASD: $F(1,118)=39.8$, $P<0.001$; childhood autism $v.$ non-ASD: $F(1,118)=186.4$, $P<0.001$; childhood autism $v.$ other-ASD: $F(1,118)=28.2$, $P<0.001$). For the SRS and CCC all three comparisons reached significance, except for the childhood autism $v.$ other-ASD comparison on the SRS (SRS: other-ASD $v.$ non-ASD: $F(1,118)=6.2$, $P<0.05$; childhood autism $v.$ non-ASD: $F(1,118)=38.7$, $P<0.001$; childhood autism $v.$ other-ASD: $F(1,118)=2.7$, $P=0.10$; CCC: other-ASD $v.$ non-ASD: $F(1,118)=13.2$, $P<0.001$; childhood autism $v.$ non-ASD: $F(1,118)=29.5$, $P<0.001$; childhood autism $v.$ other-ASD: $F(1,118)=5.3$, $P<0.05$).

Total scores on the three screening instruments were highly and significantly correlated (weighted correlation coefficients SCQ–SRS=0.68; SCQ–CCC=−0.66; SRS–CCC=−0.75, all $P<0.001$). Table 2 shows the correlations between total scores on the three screening instruments and scores on the eight other diagnostic assessment measures. All three screening instruments were more highly correlated with the ADI–R total score and ICD–10 symptom count than with the ADOS–G total score. The SCQ and SRS scores were unrelated to IQ, and scores on the CCC were only weakly related, with lower IQ being associated with poor pragmatic ability (r=0.20, $P<0.05$). All three screening instruments were unrelated to language ability as measured by the British Picture Vocabulary Scale (BPVS; Dunn *et al*, 1987). Scores on all three screens were also significantly associated with the adaptive behaviour composite of the VABS and with parent-completed, but less so with teacher-completed SDQs.

The AUC, sensitivity, specificity, positive and negative predictive values of the three screening instruments in predicting ASD versus non-ASD status are shown in Table 3 and the ROC curves are shown in Fig. 1. The SCQ had a higher AUC (0.90) than the SRS (0.77; P=0.05) and the CCC (0.79, P=0.05), reflecting both its high sensitivity (0.86) and specificity (0.78). The AUC of the SRS and CCC did not differ from one another (P=0.84). The SRS had high sensitivity (0.78) but only moderate specificity (0.67); whereas the CCC had a high sensitivity but a low specificity (0.93 and 0.46 respectively).

To examine whether the three screens performed differently in subsamples of children (children with low (<70) $v.$ high (≥70) IQ; children with $v.$ without parent- and/or teacher-rated borderline behavioural problems on the SDQ), AUC analyses were repeated for these subgroups. Note that these analyses should be treated with caution, as the confidence intervals for some of the parameters are wide, reflecting smaller subsamples. However, although the SCQ and CCC performed similarly in the subsample with low IQ as they did for the whole sample, the SRS had a lower AUC (0.67), reflecting its lower specificity (0.57). In the subsample with high IQ the AUC was similar for all three screens (SCQ=0.90; SRS=0.87; CCC=0.88). All three instruments showed lowered specificity in the subsample with elevated behavioural problems (SCQ=0.57; SRS=0.41; CCC=0.30).

Table 1 Scores on the three screening instruments by diagnostic group

	Non-ASD (n=49) Mean (s.e.)	Other-ASD (n=37) Mean (s.e.)	Childhood autism (n=33) Mean (s.e.)
SCQ	9.5 (1.1)	19.2 (1.1)	25.8 (0.5)
SRS	68.0 (6.2)	97.8 (10.2)	116.1 (4.6)
CCC	131.9 (2.7)	120.3 (1.8)	114.5 (1.8)

ASD, autistic spectrum disorder; AUC, area under the curve; CCC PC, Children's Communication Checklist, pragmatic composite; NPV, negative predictive value; PPV, positive predictive value; SCQ, Social Communication Questionnaire; SDQ, Strengths and Difficulties Questionnaire; SRS, Social Responsiveness Scale.

DISCUSSION

Summary of the screening properties

The performance of the SCQ was similar to the that in initial validation study (sensitivity=0.85; specificity=0.75; Berument *et al*, 1999; Rutter *et al*, 2003) and somewhat better than in several more recent studies that have included younger children and have reported reduced sensitivity (0.71: Eaves *et al*, 2006*a*; 0.71: Corsello *et al*, 2007; 0.67: Lee *et al*, 2007) or reduced specificity (0.71: Eaves *et al*, 2006*b*; 0.58: Allen *et al*, 2007; 0.54: Corsello *et al*, 2007). The present study included only a restricted age range but in a large sample Corsello *et al* (2007: Table 3) found that the sensitivity of the SCQ increased with age, perhaps reflecting the emergence of the full range of autistic symptoms over time. This is supported by comparison of the mean SCQ scores for children with a diagnosis of childhood autism in the present (25.8) and previous studies. Although our figure is very similar to the 25.2 obtained in the Berument *et al* (1999) study it is higher than the 20.3 obtained in the Corsello *et al* (2007) study, which included children 2–16 years and also the 19.2 of the Eaves *et al* (2006*b*) study, which included children aged 2–6 years.

The SRS had a lower sensitivity in our sample than in the original validation study (0.85; Constantino & Gruber, 2005) and both the SRS and CCC had reduced specificity (0.57 and 0.41 respectively) in our subsample with low IQ. The increased specificity of the SCQ compared with that of the SRS and CCC might be due to its fuller coverage of the third autism symptom domain of restricted and repetitive behaviours and interests. All three screens showed high discrimination between children with IQ⩾70 in the ASD and non-ASD groups with AUC values between 0.87 and 0.90. The CCC had a high sensitivity but low specificity, reflecting its broader cut-off for 'pragmatic impairment', rather than autistic-spectrum disorder itself. For some purposes, for example screening out individuals who might have autistic-spectrum disorder when characterising a non-ASD comparison group in a research study, high sensitivity is prioritised and lower specificity does not bring costs, and on the basis of the present data the CCC could be used for such a purpose. Geurts *et al* (2004) found that the CCC discriminated well between children with autism, children with ADHD and typical controls (discriminant function classification 78% in Study 1; 77% in Study 2).

All three screening instruments had lower specificity in the subsample with elevated levels of behavioural problems as measured by the SDQ. It is likely that in response to questions on the instruments that are meant to measure symptoms of autism, some parents are endorsing items that reflect aspects of their child's emotional, hyperactivity or conduct difficulties. One previous study has reported high scores on the SCQ for children with mood and anxiety disorders in whom a clinical diagnosis of pervasive developmental disorder had been excluded (Towbin *et al*, 2005), although such disorders are unlikely to be common in our sample as they usually do not form a reason for special educational needs registration. In the Towbin *et al* study significantly more children fell above the autistic-spectrum disorder cut-off on the SRS and the Social Interaction Deviance Composite on the CCC-2 than above the cut-off for the disorder on the SCQ (Towbin *et al*, 2005: Fig. 1, p. 458).

In addition to the prevalence of autistic-spectrum disorders in any particular clinical setting or research study, the characteristics (e.g. clinical diagnosis, IQ, age) of those with and without the disorder, family factors (e.g. parental education, parental knowledge about autism) and methodological factors, including whether the screen was completed before or after diagnostic assessment, will also affect how a screening

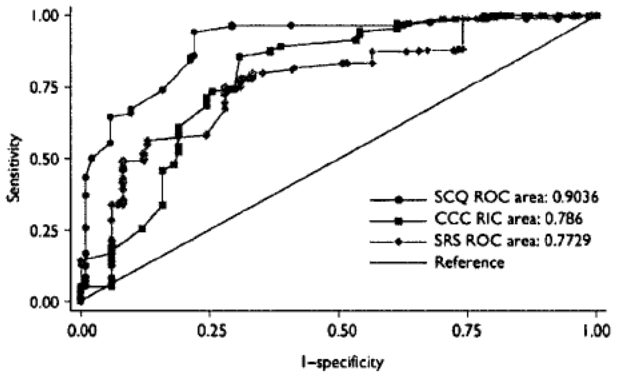

Fig. 1 Receiver operating characteristic (ROC) curves for the Social Communication Questionnaire (SCQ), Social Responsiveness Scale (SRS) and Children's Communication Checklist (CCC).

instrument performs. Another factor that affects an instrument's performance in relation to a clinical diagnosis of autistic-spectrum disorder is the time period of the behaviour sampled and the three instruments used in this study differed in this respect. Whereas the CCC and SRS ask parents to rate current behaviour (for the SRS over the previous 6 months; unspecified for the CCC), about half of the items on the SCQ ask about behaviour in the 4- to 5-year period when symptoms of autism may be at their most prototypical. One further consideration that our study cannot address is whether screening instruments perform differently in different countries owing to cultural interpretation of the behaviours enquired about.

Example scenarios comparing use of the three screens

The meaning of statistics such as the AUC can be hard to translate into everyday examples to guide clinicians and researchers. To illustrate the potential impact of the different screen parameters on a hypothetical research study or clinical service we will outline two scenarios that summarise the consequences of choice of screening instrument. In both scenarios assume that among 250 children to be screened, 100 are 'true cases' of autistic-spectrum disorders and 150 are 'true non-cases'. Using estimates from the present analysis this translates into: the number of the 100 'true cases' that are screen positive (true positives) (SCQ=86; SRS=78; CCC pragmatic composite=93); the number of the 100 'true cases' that are screen negative (false negatives) (SCQ=14; SRS=22; CCC pragmatic composite=7); the number of the 150 true non-cases that are screen negative (true negatives) (SCQ=117; SRS=100.5; CCC pragmatic composite=69); and the number of the 150 true non-cases that are screen positive (false positives) (SCQ=33; SRS=49.5; CCC pragmatic composite=81). The relative importance of these figures depends on the purpose of using the screening instrument in a particular study/service.

In the first scenario, consider that the instruments is being used to estimate, for purely administrative reasons, the number of children within a special school system who have an autistic-spectrum disorder. That is, there is no consequence or cost (such as a follow-up assessment) attached to being screen positive. In this scenario, the estimated prevalence of autistic-spectrum disorder will vary by a factor of ~50%, depending on whether one is using the SCQ (119 screen positives, i.e. children with autistic-spectrum disorders identified), the SRS (127.5 identified) or the CCC pragmatic composite (173 identified), with the latter clearly overestimating the 'true' prevalence.

In a second scenario, consider a clinical service screening speech and language therapy referrals to identify children who should be 'fast tracked' into an expensive (and for parents sometimes anxiety provoking) multidisciplinary assessment. For this aim, high sensitivity is required for the screening procedure to be clinically useful. To maximise case-finding efficiency one could consider the proportion of cases correctly identified by the screen compared with cases missed by it (SCQ=6.14; SRS=3.55; CCC pragmatic composite=13.3). However, one would also want to minimise false positives in order not to use expensive assessment resource on children who do not have autistic-spectrum disorders and to avoid provoking unnecessary anxiety in parents. Here the most relevant figure is the number of false positives (SCQ=33; SRS=49.5; CCC pragmatic composite=81). In this scenario the SRS was least efficient in terms of case-finding and the CCC least cost-effective, with the SCQ performing best. Other scenarios would produce different outcomes, and the choice of which screen to use and which criterion to adopt could depend on the relative costs of false positives and false negatives – although these costs fall on different parties (false positives tend to cost services, whereas false negatives tend to cost the child and parent). Clinicians and researchers need to estimate as best they can the implications for their service/study of which screen they use for any particular purpose.

Strengths and limitations

The strengths of our study include: testing the ability of different screening instruments to identify children with autistic-spectrum disorders in the same sample; the generalisability of the findings, owing to the population-weighting procedure; the calculation of confidence intervals around the instrument parameter estimates; and the inclusion of both low- and high-IQ children. The comprehensive diagnostic assessment and use of a clinical consensus decision-making process that was corroborated by independent expert rating (see Baird *et al*, 2006) are also strengths. Furthermore, the screens were able to differentiate those with autistic-spectrum disorders from those without such disorders but with intellectual disability and language delay despite the considerable degree of symptom overlap between these conditions, especially in the area of impairments in communication.

One limitation of the study is that the age of the at-risk sample at the time of screening (9–13 years) is older than would be required for first-level screening of young children, although it is still an age at which many children are referred for possible autistic-spectrum disorders, in particular to child and adolescent mental health services (Skuse *et al*, 2005). Second, the SCQ was derived from items on the ADI–R and information from the ADI–R was part of the information used to achieve a clinical consensus diagnosis. This might explain, in part, the higher prediction of the SCQ compared with the SRS and CCC that we found. Another limitation is the

relatively modest sample size, in particular when the subsamples with high/low IQ and high/low levels of behavioural problems were examined, leading to relatively wide confidence intervals. However, the sample size compares well with the majority of published data available on the SCQ, SRS and CCC.

Clinical implications

A score on a screening instrument is not a diagnosis. For diagnostic assessment a full parental interview regarding current and past development and behaviour, and structured observation of the child, preferably including a peer-group setting, is essential. Corsello *et al* (2007) found that the addition of information from the ADOS–G to information from the SCQ significantly improved specificity to detect autistic-spectrum disorders. For some clinical and research purposes they suggest that a multi-stage assessment beginning with the SCQ, followed by the ADOS–G and then including information from the time-intensive ADI–R assessment might be appropriate. Our study demonstrates that for some clinical and research purposes the SCQ, and to a lesser extent the SRS and CCC, can all be efficient first-level screening instruments for identifying children with possible autistic-spectrum disorder for a more in-depth assessment. Child characteristics such as IQ and behavioural problems affect performance of the screens, and this, in addition to considerations regarding the consequences/costs of a screen-positive or negative result, should be borne in mind when choosing which screen to use for any particular clinical or research purpose.

ACKNOWLEDGEMENTS

We are grateful to the children and families who participated in the study and to the clinical teams in South Thames, whose collaboration made the study possible. We thank the expert group, Patrick Bolton, Antony Cox, Anne Gilchrist, Rebecca Landa, Ann Le Couteur, Catherine Lord, Lennart Pedersen and Michael Rutter. Thanks also to Iris Carcani-Rathwell, Greg Pasco, Samantha Ross, Emma Rowley, Vicky Slonims and Martha Turner for their help with assessments, and to Dorothy Bishop for comments on an earlier version of this manuscript.

Not until the middle of the twentieth century was there a name for a disorder that now appears to affect an estimated one of every five hundred children, a disorder that causes disruption in families and unfulfilled lives for many children. In 1943 Dr. Leo Kanner of the Johns Hopkins Hospital studied a group of 11 children and introduced the label *early infantile autism* into the English language. At the same time a German scientist, Dr. Hans Asperger, described a milder form of the disorder that became known as Asperger syndrome. Thus these two disorders were described and are today listed in the *Diagnostic and Statistical Manual of Mental Disorders* DSM-IV-TR (fourth edition, text revision)[1] as two of the five pervasive developmental disorders (PDD), more often referred to today as autism spectrum disorders (ASD). All these disorders are characterized by varying degrees of impairment in communication skills, social interactions, and restricted, repetitive and stereotyped patterns of behavior.

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

The autism spectrum disorders can often be reliably detected by the age of 3 years, and in some cases as early as 18 months.[2] Studies suggest that many children eventually may be accurately identified by the age of 1 year or even younger. The appearance of any of the warning signs of ASD is reason to have a child evaluated by a professional specializing in these disorders.

Parents are usually the first to notice unusual behaviors in their child. In some cases, the baby seemed "different" from birth, unresponsive to people or focusing intently on one item for long periods of time. The first signs of an ASD can also appear in children who seem to have been developing normally. When an engaging, babbling toddler suddenly becomes silent, withdrawn, self-abusive, or indifferent to social overtures, something is wrong. Research has shown that parents are usually correct about noticing developmental problems, although they may not realize the specific nature or degree of the problem.

The pervasive developmental disorders, or autism spectrum disorders, range from a severe form, called autistic disorder, to a milder form, Asperger syndrome. If a child has symptoms of either of these disorders, but does not meet the specific criteria for either, the diagnosis is called pervasive developmental disorder not otherwise specified (PDD-NOS). Other rare, very severe disorders that are included in the autism spectrum disorders are Rett syndrome and childhood disintegrative disorder. This brochure will focus on classic autism, PDD-NOS, and Asperger syndrome, with brief descriptions of Rett syndrome and childhood disintegrative disorder on the following page.

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

Rare Autism Spectrum Disorders

Rett Syndrome: Rett syndrome is relatively rare, affecting almost exclusively females, one out of 10,000 to 15,000. After a period of normal development, sometime between 6 and 18 months, autism-like symptoms begin to appear. The little girl's mental and social development regresses—she no longer responds to her parents and pulls away from any social contact. If she has been talking, she stops; she cannot control her feet; she wrings her hands. Some of the problems associated with Rett syndrome can be treated. Physical, occupational, and speech therapy can help with problems of coordination, movement, and speech.

Scientists sponsored by the National Institute of Child Health and Human Development have discovered that a mutation in the sequence of a single gene can cause Rett syndrome. This discovery may help doctors slow or stop the progress of the syndrome. It may also lead to methods of screening for Rett syndrome, thus enabling doctors to start treating these children much sooner, and improving the quality of life these children experience.*

Childhood Disintegrative Disorder: Very few children who have an autism spectrum disorder (ASD) diagnosis meet the criteria for childhood disintegrative disorder (CDD). An estimate based on four surveys of ASD found fewer than 2 children per 100,000 with ASD could be classified as having CDD. This suggests that CDD is a very rare form of ASD. It has a strong male preponderance.** Symptoms may appear by age 2, but the average age of onset is between 3 and 4 years. Until this time, the child has age-appropriate skills in communication and social relationships. The long period of normal development before regression helps differentiate CDD from Rett syndrome.

The loss of such skills as vocabulary are more dramatic in CDD than they are in classical autism. The diagnosis requires extensive and pronounced losses involving motor, language, and social skills.*** CDD is also accompanied by loss of bowel and bladder control and oftentimes seizures and a very low IQ.

What Are the Autism Spectrum Disorders?

The autism spectrum disorders are more common in the pediatric population than are some better known disorders such as diabetes, spinal bifida, or Down syndrome.[2] Prevalence studies have been done in several states and also in the United Kingdom, Europe, and Asia. Prevalence estimates range from 2 to 6 per 1,000 children. This wide range of prevalence points to a need for earlier and more accurate screening for the symptoms of ASD. The earlier the disorder is diagnosed, the sooner the child can be helped through treatment interventions. Pediatricians, family physicians, daycare providers, teachers, and parents may initially dismiss signs of ASD, optimistically thinking the child is just a little slow and will "catch up." Although early intervention has a dramatic impact on reducing symptoms and increasing a child's ability to grow and learn new skills, it is estimated that *only 50% of children are diagnosed before kindergarten.*

All children with ASD demonstrate deficits in 1) social interaction, 2) verbal and nonverbal communication, and 3) repetitive behaviors or interests. In addition, they will often have unusual responses to sensory experiences, such as certain sounds or the way objects look. Each of these symptoms runs the gamut from mild to severe. They will present in each individual child differently. For instance, a child may have little trouble learning to read but exhibit extremely poor social interaction. Each child will display communication, social, and behavioral patterns that are individual but fit into the overall diagnosis of ASD.

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

Children with ASD do not follow the typical patterns of child development. In some children, hints of future problems may be apparent from birth. In most cases, the problems in communication and social skills become more noticeable as the child lags further behind other children the same age. Some other children start off well enough. Oftentimes between 12 and 36 months old, the differences in the way they react to people and other unusual behaviors become apparent. Some parents report the change as being sudden, and that their children start to reject people, act strangely, and lose language and social skills they had previously acquired. In other cases, there is a "plateau," or leveling, of progress so that the difference between the child with autism and other children the same age becomes more noticeable.

ASD is defined by a certain set of behaviors that can range from the very mild to the severe. The following possible indicators of ASD were identified on the Public Health Training Network Webcast, *Autism Among Us*.[3]

Possible Indicators of Autism Spectrum Disorders

- Does not babble, point, or make meaningful gestures by 1 year of age
- Does not speak one word by 16 months
- Does not combine two words by 2 years.
- Does not respond to name
- Loses language or social skills

Some Other Indicators

- Poor eye contact
- Doesn't seem to know how to play with toys

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

- Excessively lines up toys or other objects
- Is attached to one particular toy or object
- Doesn't smile
- At times seems to be hearing impaired

Social Symptoms

From the start, typically developing infants are social beings. Early in life, they gaze at people, turn toward voices, grasp a finger, and even smile.

In contrast, most children with ASD seem to have tremendous difficulty learning to engage in the give-and-take of everyday human interaction. Even in the first few months of life, many do not interact and they avoid eye contact. They seem indifferent to other people, and often seem to prefer being alone. They may resist attention or passively accept hugs and cuddling. Later, they seldom seek comfort or respond to parents' displays of anger or affection in a typical way. Research has suggested that although children with ASD are attached to their parents, their expression of this attachment is unusual and difficult to "read." To parents, it may seem as if their child is not attached at all Parents who looked forward to the joys of cuddling, teaching, and playing with their child may feel crushed by this lack of the expected and typical attachment behavior.

Children with ASD also are slower in learning to interpret what others are thinking and feeling. Subtle social cues—whether a smile, a wink, or a grimace—may have little meaning. To a child who misses these cues, "Come here" always means the same thing, whether the speaker is smiling and extending her arms for a hug or frowning and planting her fists on her hips. Without the ability to

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

interpret gestures and facial expressions, the social world may seem bewildering.

To compound the problem, people with ASD have difficulty seeing things from another person's perspective. Most 5-year-olds understand that other people have different information, feelings, and goals than they have. A person with ASD may lack such understanding. This inability leaves them unable to predict or understand other people's actions.

Although not universal, it is common for people with ASD also to have difficulty regulating their emotions. This can take the form of "immature" behavior such as crying in class or verbal outbursts that seem inappropriate to those around them. The individual with ASD might also be disruptive and physically aggressive at times, making social relationships still more difficult. They have a tendency to "lose control," particularly when they're in a strange or overwhelming environment, or when angry and frustrated. They may at times break things, attack others, or hurt themselves. In their frustration, some bang their heads, pull their hair, or bite their arms.

Communication Difficulties

By age 3, most children have passed predictable milestones on the path to learning language; one of the earliest is babbling. By the first birthday, a typical toddler says words, turns when he hears his name, points when he wants a toy, and when offered something distasteful, makes it clear that the answer is "no."

Some children diagnosed with ASD remain mute throughout their lives. Some infants who later show signs of ASD coo and babble during the first few months of life, but they soon stop. Others may be delayed, developing language as late as age 5 to 9.

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

Some children may learn to use communication systems such as pictures or sign language.

Those who do speak often use language in unusual ways. They seem unable to combine words into meaningful sentences. Some speak only single words, while others repeat the same phrase over and over. Some ASD children parrot what they hear, a condition called *echolalia*. Although many children with no ASD go through a stage where they repeat what they hear, it normally passes by the time they are 3.

Some children only mildly affected may exhibit slight delays in language, or even seem to have precocious language and unusually large vocabularies, but have great difficulty in sustaining a conversation. The "give and take" of normal conversation is hard for them, although they often carry on a monologue on a favorite subject, giving no one else an opportunity to comment. Another difficulty is often the inability to understand body language, tone of voice, or "phrases of speech." They might interpret a sarcastic expression such as "Oh, that's just great" as meaning it really IS great.

While it can be hard to understand what ASD children are saying, their body language is also difficult to understand. Facial expressions, movements, and gestures rarely match what they are saying. Also, their tone of voice fails to reflect their feelings. A high-pitched, sing-song, or flat, robot-like voice is common. Some children with relatively good language skills speak like little adults, failing to pick up on the "kid-speak" that is common in their peers.

Without meaningful gestures or the language to ask for things, people with ASD are at a loss to let others know what they need. As a result, they may simply scream or grab what they want. Until they are taught better ways to express their needs, ASD

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

children do whatever they can to get through to others. As people with ASD grow up, they can become increasingly aware of their difficulties in understanding others and in being understood. As a result they may become anxious or depressed.

Repetitive Behaviors

Although children with ASD usually appear physically normal and have good muscle control, odd repetitive motions may set them off from other children. These behaviors might be extreme and highly apparent or more subtle. Some children and older individuals spend a lot of time repeatedly flapping their arms or walking on their toes. Some suddenly freeze in position.

As children, they might spend hours lining up their cars and trains in a certain way, rather than using them for pretend play. If someone accidentally moves one of the toys, the child may be tremendously upset. ASD children need, and demand, absolute consistency in their environment. A slight change in any routine—in mealtimes, dressing, taking a bath, going to school at a certain time and by the same route—can be extremely disturbing. Perhaps order and sameness lend some stability in a world of confusion.

Repetitive behavior sometimes takes the form of a persistent, intense preoccupation. For example, the child might be obsessed with learning all about vacuum cleaners, train schedules, or lighthouses. Often there is great interest in numbers, symbols, or science topics.

Problems that May Accompany ASD

Sensory problems. When children's perceptions are accurate, they can learn from what they see, feel, or hear. On the

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

other hand, if sensory information is faulty, the child's experiences of the world can be confusing. Many ASD children are highly attuned or even painfully sensitive to certain sounds, textures, tastes, and smells. Some children find the feel of clothes touching their skin almost unbearable. Some sounds—a vacuum cleaner, a ringing telephone, a sudden storm, even the sound of waves lapping the shoreline—will cause these children to cover their ears and scream.

In ASD, the brain seems unable to balance the senses appropriately. Some ASD children are oblivious to extreme cold or pain. An ASD child may fall and break an arm, yet never cry. Another may bash his head against a wall and not wince, but a light touch may make the child scream with alarm.

Mental retardation. Many children with ASD have some degree of mental impairment. When tested, some areas of ability may be normal, while others may be especially weak. For example, a child with ASD may do well on the parts of the test that measure visual skills but earn low scores on the language subtests.

Seizures. One in four children with ASD develops seizures, often starting either in early childhood or adolescence.[4] Seizures, caused by abnormal electrical activity in the brain, can produce a temporary loss of consciousness (a "blackout"), a body convulsion, unusual movements, or staring spells. Sometimes a contributing factor is a lack of sleep or a high fever. An EEG (electro-encephalogram— recording of the electric currents developed in the brain by means of electrodes applied to the scalp) can help confirm the seizure's presence.

In most cases, seizures can be controlled by a number of medicines called "anticonvulsants." The dosage of the medication is adjusted carefully so that the least possible amount of medication

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

will be used to be effective.

Fragile X syndrome. This disorder is the most common inherited form of mental retardation. It was so named because one part of the X chromosome has a defective piece that appears pinched and fragile when under a microscope. Fragile X syndrome affects about two to five percent of people with ASD. It is important to have a child with ASD checked for Fragile X, especially if the parents are considering having another child. For an unknown reason, if a child with ASD also has Fragile X, there is a one-in-two chance that boys born to the same parents will have the syndrome.[5] Other members of the family who may be contemplating having a child may also wish to be checked for the syndrome.

Tuberous Sclerosis. Tuberous sclerosis is a rare genetic disorder that causes benign tumors to grow in the brain as well as in other vital organs. It has a consistently strong association with ASD. One to 4 percent of people with ASD also have tuberous sclerosis.[6]

The Diagnosis of Autism Spectrum Disorders

Although there are many concerns about labeling a young child with an ASD, the earlier the diagnosis of ASD is made, the earlier needed interventions can begin. Evidence over the last 15 years indicates that intensive early intervention in *optimal educational settings for at least 2 years during the preschool years* results in improved outcomes in most young children with ASD.[2]

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

In evaluating a child, clinicians rely on behavioral characteristics to make a diagnosis. Some of the characteristic behaviors of ASD may be apparent in the first few months of a child's life, or they may appear at any time during the early years. For the diagnosis, problems in at least one of the areas of communication, socialization, or restricted behavior must be present before the age of 3. The diagnosis requires a two-stage process. The first stage involves developmental screening during 'well child" check-ups; the second stage entails a comprehensive evaluation by a multidisciplinary team.[7]

Screening

A "well child" check-up should include a developmental screening test. If your child's pediatrician does not routinely check your child with such a test, ask that it be done. Your own observations and concerns about your child's development will be essential in helping to screen your child.[7] Reviewing family videotapes, photos, and baby albums can help parents remember when each behavior was first noticed and when the child reached certain developmental milestones.

Several screening instruments have been developed to quickly gather information about a child's social and communicative development within medical settings. Among them are the Checklist of Autism in Toddlers (CHAT),[8] the modified Checklist for Autism in Toddlers (M-CHAT),[9] the Screening Tool for Autism in Two-Year-Olds (STAT),[10] and the Social Communication Questionnaire (SCQ)[11] (for children 4 years of age and older).

Some screening instruments rely solely on parent responses to a questionnaire, and some rely on a combination of parent report and observation. Key items on these instruments that appear to

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

differentiate children with autism from other groups before the age of 2 include pointing and pretend play. Screening instruments do not provide individual diagnosis but serve to assess the need for referral for possible diagnosis of ASD. These screening methods may not identify children with mild ASD, such as those with high-functioning autism or Asperger syndrome.

During the last few years, screening instruments have been devised to screen for Asperger syndrome and higher functioning autism. The Autism Spectrum Screening Questionnaire (ASSQ),[12] the Australian Scale for Asperger's Syndrome,[13] and the most recent, the Childhood Asperger Syndrome Test (CAST),[14] are some of the instruments that are reliable for identification of school-age children with Asperger syndrome or higher functioning autism. These tools concentrate on social and behavioral impairments in children without significant language delay.

If, following the screening process or during a routine "well child" check-up, your child's doctor sees any of the possible indicators of ASD, further evaluation is indicated.

Comprehensive Diagnostic Evaluation

The second stage of diagnosis must be comprehensive in order to accurately rule in or rule out an ASD or other developmental problem. This evaluation may be done by a multidisciplinary team that includes a psychologist, a neurologist, a psychiatrist, a speech therapist, or other professionals who diagnose children with ASD.

Because ASD's are complex disorders and may involve other neurological or genetic problems, a comprehensive evaluation should entail neurologic and genetic assessment, along with in-depth cognitive and language testing.[7] In addition, measures developed specifically for diagnosing autism are often used. These

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

include the Autism Diagnosis Interview-Revised (ADI-R)[15] and the Autism Diagnostic Observation Schedule (ADOS-G).[16] The ADI-R is a structured interview that contains over 100 items and is conducted with a caregiver. It consists of four main factors—the child's communication, social interaction, repetitive behaviors, and age-of-onset symptoms. The ADOS-G is an observational measure used to "press" for socio-communicative behaviors that are often delayed, abnormal, or absent in children with ASD.

Still another instrument often used by professionals is the Childhood Autism Rating Scale (CARS).[17] It aids in evaluating the child's body movements, adaptation to change, listening response, verbal communication, and relationship to people. It is suitable for use with children over 2 years of age. The examiner observes the child and also obtains relevant information from the parents. The child's behavior is rated on a scale based on deviation from the typical behavior of children of the same age.

Two other tests that should be used to assess any child with a developmental delay are a formal audiologic hearing evaluation and a lead screening. Although some hearing loss can co-occur with ASD, some children with ASD may be incorrectly thought to have such a loss. In addition, if the child has suffered from an ear infection, transient hearing loss can occur. Lead screening is essential for children who remain for a long period of time in the oral-motor stage in which they put any and everything into their mouths. Children with an autistic disorder usually have elevated blood lead levels.[7]

Customarily, an expert diagnostic team has the responsibility of thoroughly evaluating the child, assessing the child's unique strengths and weaknesses, and determining a formal diagnosis.

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

The team will then meet with the parents to explain the results of the evaluation.

Although parents may have been aware that something was not "quite right" with their child, when the diagnosis is given, it is a devastating blow. At such a time, it is hard to stay focused on asking questions. But while members of the evaluation team are together is the best opportunity the parents will have to ask questions and get recommendations on what further steps they should take for their child. Learning as much as possible at this meeting is very important, but it is helpful to leave this meeting with the name or names of professionals who can be contacted if the parents have further questions.

Available Aids

When your child has been evaluated and diagnosed with an autism spectrum disorder, you may feel inadequate to help your child develop to the fullest extent of his or her ability. As you begin to look at treatment options and at the types of aid available for a child with a disability, you will find out that there is help for you. It is going to be difficult to learn and remember everything you need to know about the resources that will be most helpful. *Write down everything.* If you keep a notebook, you will have a foolproof method of recalling information. Keep a record of the doctors' reports and the evaluation your child has been given so that his or her eligibility for special programs will be documented. Learn everything you can about special programs for your child; the more you know, the more effectively you can advocate.

For every child eligible for special programs, each state guarantees special education and related services. The Individuals

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

with Disabilities Education Act (IDEA) is a Federally mandated program that assures a free and appropriate public education for children with diagnosed learning deficits. Usually children are placed in public schools and the school district pays for all necessary services. These will include, as needed, services by a speech therapist, occupational therapist, school psychologist, social worker, school nurse, or aide.

By law, the public schools must prepare and carry out a set of instruction goals, or specific skills, for every child in a special education program. The list of skills is known as the child's Individualized Education Program (IEP). The IEP is an agreement between the school and the family on the child's goals. When your child's IEP is developed, you will be asked to attend the meeting. There will be several people at this meeting, including a special education teacher, a representative of the public schools who is knowledgeable about the program, other individuals invited by the school or by you (you may want to bring a relative, a child care provider, or a supportive close friend who knows your child well). Parents play an important part in creating the program, as they know their child and his or her needs best. Once your child's IEP is developed, a meeting is scheduled once a year to review your child's progress and to make any alterations to reflect his or her changing needs.

If your child is under 3 years of age and has special needs, he or she should be eligible for an early intervention program; this program is available in every state. Each state decides which agency will be the lead agency in the early intervention program. The early intervention services are provided by workers qualified to care for toddlers with disabilities and are usually in the child's home

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

or a place familiar to the child. The services provided are written into an Individualized Family Service Plan (IFSP) that is reviewed at least once every 6 months. The plan will describe services that will be provided to the child, but will also describe services for parents to help them in daily activities with their child and for siblings to help them adjust to having a brother or sister with ASD.

There is a list of resources at the back of the brochure that will be helpful to you as you look for programs for your child.

Treatment Options

There is no single best treatment package for all children with ASD. One point that most professionals agree on is that early intervention is important; another is that most individuals with ASD respond well to highly structured, specialized programs.

Before you make decisions on your child's treatment, you will want to gather information about the various options available. Learn as much as you can, look at all the options, and make your decision on your child's treatment based on your child's needs. You may want to visit public schools in your area to see the type of program they offer to special needs children.

Guidelines used by the Autism Society of America include the following questions parents can ask about potential treatments:

- Will the treatment result in harm to my child?
- How will failure of the treatment affect my child and family?
- Has the treatment been validated scientifically?
- Are there assessment procedures specified?
- How will the treatment be integrated into my child's current program? Do not become so infatuated with a given

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

treatment that functional curriculum, vocational life and social skills are ignored.

The National Institute of Mental Health suggests a list of questions parents can ask when planning for their child:

- How successful has the program been for other children?
- How many children have gone on to placement in a regular school and how have they performed?
- Do staff members have training and experience in working with children and adolescents with autism?
- How are activities planned and organized?
- Are there predictable daily schedules and routines?
- How much individual attention will my child receive?
- How is progress measured? Will my child's behavior be closely observed and recorded?
- Will my child be given tasks and rewards that are personally motivating?
- Is the environment designed to minimize distractions?
- Will the program prepare me to continue the therapy at home?
- What is the cost, time commitment, and location of the program?

Among the many methods available for treatment and education of people with autism, applied behavior analysis (ABA) has become widely accepted as an effective treatment. *Mental Health: A Report of the Surgeon General* states, "Thirty years of research demonstrated the efficacy of applied behavioral methods in reducing inappropriate behavior and in increasing communication, learning, and appropriate social behavior."[18] The basic research

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

done by Ivar Lovaas and his colleagues at the University of California, Los Angeles, calling for an intensive, one-on-one child-teacher interaction for 40 hours a week, laid a foundation for other educators and researchers in the search for further effective early interventions to help those with ASD attain their potential. The goal of behavioral management is to reinforce desirable behaviors and reduce undesirable ones.[19,20]

An effective treatment program will build on the child's interests, offer a predictable schedule, teach tasks as a series of simple steps, actively engage the child's attention in highly structured activities, and provide regular reinforcement of behavior. Parental involvement has emerged as a major factor in treatment success. Parents work with teachers and therapists to identify the behaviors to be changed and the skills to be taught. Recognizing that parents are the child's earliest teachers, more programs are beginning to train parents to continue the therapy at home.

As soon as a child's disability has been identified, instruction should begin. Effective programs will teach early communication and social interaction skills. In children younger than 3 years, appropriate interventions usually take place in the home or a child care center. These interventions target specific deficits in learning, language, imitation, attention, motivation, compliance, and initiative of interaction. Included are behavioral methods, communication, occupational and physical therapy along with social play interventions. Often the day will begin with a physical activity to help develop coordination and body awareness; children string beads, piece puzzles together, paint, and participate in other motor skills activities. At snack time the teacher encourages social interaction and models how to use language to ask for more juice. The children learn by doing. Working with the children are

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

students, behavioral therapists, and parents who have received extensive training. In teaching the children, positive reinforcement is used.[21]

Children older than 3 years usually have school-based, individualized, special education. The child may be in a segregated class with other autistic children or in an integrated class with children without disabilities for at least part of the day. Different localities may use differing methods but all should provide a structure that will help the children learn social skills and, functional communication. In these programs, teachers often involve the parents, giving useful advice in how to help their child use the skills or behaviors learned at school when they are at home.[22]

In elementary school, the child should receive help in any skill area that is delayed and, at the same time, be encouraged to grow in his or her areas of strength. Ideally, the curriculum should be adapted to the individual child's needs. Many schools today have an inclusion program in which the child is in a regular classroom for most of the day, with special instruction for a part of the day. This instruction should include such skills as learning how to act in social situations and in making friends. Although higher-functioning children may be able to handle academic work, they too need help to organize tasks and avoid distractions.

During middle and high school years, instruction will begin to address such practical matters as work, community living, and recreational activities. This should include work experience, using public transportation, and learning skills that will be important in community living.[23]

All through your child's school years, you will want to be an active participant in his or her education program. Collaboration

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

The Adolescent Years

Adolescence is a time of stress and confusion; and it is no less so for teenagers with autism. Like all children, they need help in dealing with their budding sexuality. While some behaviors improve during the teenage years, some get worse. Increased autistic or aggressive behavior may be one way some teens express their newfound tension and confusion.

The teenage years are also a time when children become more socially sensitive. At the age that most teenagers are concerned with acne, popularity, grades, and dates, teens with autism may become painfully aware that they are different from their peers. They may notice that they lack friends. And unlike their schoolmates, they aren't dating or planning for a career. For some, the sadness that comes with such realization motivates them to learn new behaviors and acquire better social skills.

between parents and educators is essential in evaluating your child's progress.

Dietary and Other Interventions

In an effort to do everything possible to help their children, many parents continually seek new treatments. Some treatments are developed by reputable therapists or by parents of a child with ASD. Although an unproven treatment may help one child, it may not prove beneficial to another. To be accepted as a proven treatment, the treatment should undergo clinical trials, preferably randomized, double-blind trials, that would allow for a comparison between treatment and no treatment. Following are some of the interventions that have been reported to have been helpful to some children but whose efficacy or safety has not been proven.

Dietary interventions are based on the idea that 1) food allergies cause symptoms of autism, and 2) an insufficiency of a specific vitamin or mineral may cause some autistic symptoms. If

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

parents decide to try for a given period of time a special diet, they should be sure that the child's nutritional status is measured carefully.

A diet that some parents have found was helpful to their autistic child is a gluten-free, casein-free diet. Gluten is a casein-like substance that is found in the seeds of various cereal plants—wheat, oat, rye, and barley. Casein is the principal protein in milk. Since gluten and milk are found in many of the foods we eat, following a gluten-free, casein-free diet is difficult.

A supplement that some parents feel is beneficial for an autistic child is Vitamin B6, taken with magnesium (which makes the vitamin effective). The result of research studies is mixed; some children respond positively, some negatively, some not at all or very little.[4]

In the search for treatment for autism, there has been discussion in the last few years about the use of secretin, a substance approved by the Food and Drug Administration (FDA) for a single dose normally given to aid in diagnosis of a gastrointestinal problem. Anecdotal reports have shown improvement in autism symptoms, including sleep patterns, eye contact, language skills, and alertness. Several clinical trials conducted in the last few years have found no significant improvements in symptoms between patients who received secretin and those who received a placebo.[24]

Medications Used in Treatment

Medications are often used to treat behavioral problems, such as aggression, self-injurious behavior, and severe tantrums, that keep the person with ASD from functioning more effectively at home or school. The medications used are those that have been developed to treat similar symptoms in other disorders. Many of these

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

medications are prescribed "off-label." This means they have not been officially approved by the FDA for use in children, but the doctor prescribes the medications if he or she feels they are appropriate for your child. Further research needs to be done to ensure not only the efficacy but the safety of psychotropic agents used in the treatment of children and adolescents.

A child with ASD may not respond in the same way to medications as typically developing children. It is important that parents work with a doctor who has experience with children with autism. A child should be monitored closely while taking a medication. The doctor will prescribe the lowest dose possible to be effective. Ask the doctor about any side effects the medication may have and keep a record of how your child responds to the medication. It will be helpful to read the "patient insert" that comes with your child's medication. Some people keep the patient inserts in a small notebook to be used as a reference. This is most useful when several medications are prescribed.

Anxiety and depression. The selective serotonin reuptake inhibitors (SSRI's) are the medications most often prescribed for symptoms of anxiety, depression, and/or obsessive-compulsive disorder (OCD). Only one of the SSRI's, fluoxetine, (Prozac®) has been approved by the FDA for both OCD and depression in children age 7 and older. Three that have been approved for OCD are fluvoxamine (Luvox®), age 8 and older; sertraline (Zoloft®), age 6 and older; and clomipramine (Anafranil®), age 10 and older.[4] Treatment with these medications can be associated with decreased frequency of repetitive, ritualistic behavior and improvements in eye contact and social contacts. The FDA is studying and analyzing

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

data to better understand how to use the SSRI's safely, effectively, and at the lowest dose possible.

Behavioral problems. Antipsychotic medications have been used to treat severe behavioral problems. These medications work by reducing the activity in the brain of the neurotransmitter dopamine. Among the older, typical antipsychotics, such as haloperidol (Haldol®), thioridazine, fluphenazine, and chlorpromazine, haloperidol was found in more than one study to be more effective than a placebo in treating serious behavioral problems.[25] However, haloperidol, while helpful for reducing symptoms of aggression, can also have adverse side effects, such as sedation, muscle stiffness, and abnormal movements.

Placebo-controlled studies of the newer "atypical" antipsychotics are being conducted on children with autism. The first such study, conducted by the NIMH-supported Research Units on Pediatric Psychopharmacology (RUPP) Autism Network, was on risperidone (Risperdal®).[26] Results of the 8-week study were reported in 2002 and showed that risperidone was effective and well tolerated for the treatment of severe behavioral problems in children with autism. The most common side effects were increased appetite, weight gain and sedation. Further long-term studies are needed to determine any long-term side effects. Other atypical antipsychotics that have been studied recently with encouraging results are olanzapine (Zyprexa®) and ziprasidone (Geodon®). Ziprasidone has not been associated with significant weight gain.

Seizures. Seizures are found in one in four persons with ASD, most often in those who have low IQ or are mute. They are treated with one or more of the anticonvulsants. These include such medications as carbamazepine (Tegretol®), lamotrigine (Lamictal®), topiramate (Topamax®), and valproic acid (Depakote®). The level

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

of the medication in the blood should be monitored carefully and adjusted so that the least amount possible is used to be effective. Although medication usually reduces the number of seizures, it cannot always eliminate them.

Inattention and hyperactivity. Stimulant medications such as methylphenidate (Ritalin®), used safely and effectively in persons with attention deficit hyperactivity disorder, have also been prescribed for children with autism. These medications may decrease impulsivity and hyperactivity in some children, especially those higher functioning children.

Several other medications have been used to treat ASD symptoms; among them are other antidepressants, naltrexone, lithium, and some of the benzodiazepines such as diazepam (Valium®) and lorazepam (Ativan®). The safety and efficacy of these medications in children with autism has not been proven. Since people may respond differently to different medications, your child's unique history and behavior will help your doctor decide which medication might be most beneficial.

Adults with an Autism Spectrum Disorder

Some adults with ASD, especially those with high-functioning autism or with Asperger syndrome, are able to work successfully in mainstream jobs. Nevertheless, communication and social problems often cause difficulties in many areas of life. They will continue to need encouragement and moral support in their struggle for an independent life.

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

Many others with ASD are capable of employment in sheltered workshops under the supervision of managers trained in working with persons with disabilities. A nurturing environment at home, at school, and later in job training and at work, helps persons with ASD continue to learn and to develop throughout their lives.

The public schools' responsibility for providing services ends when the person with ASD reaches the age of 22. The family is then faced with the challenge of finding living arrangements and employment to match the particular needs of their adult child, as well as the programs and facilities that can provide support services to achieve these goals. Long before your child finishes school, you will want to search for the best programs and facilities for your young adult. If you know other parents of ASD adults, ask them about the services available in your community. If your community has little to offer, serve as an advocate for your child and work toward the goal of improved employment services. Research the resources listed in the back of this brochure to learn as much as possible about the help your child is eligible to receive as an adult.

Living Arrangements for the Adult with an Autism Spectrum Disorder

Independent living. Some adults with ASD are able to live entirely on their own. Others can live semi-independently in their own home or apartment if they have assistance with solving major problems, such as personal finances or dealing with the government agencies that provide services to persons with disabilities. This assistance can be provided by family, a professional agency, or another type of provider.

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

Living at home. Government funds are available for families that choose to have their adult child with ASD live at home. These programs include Supplemental Security Income (SSI), Social Security Disability Insurance (SSDI), Medicaid waivers, and others. Information about these programs is available from the Social Security Administration (SSA). An appointment with a local SSA office is a good first step to take in understanding the programs for which the young adult is eligible.

Foster homes and skill-development homes. Some families open their homes to provide long-term care to unrelated adults with disabilities. If the home teaches self-care and housekeeping skills and arranges leisure activities, it is called a "skill-development" home.

Supervised group living. Persons with disabilities frequently live in group homes or apartments staffed by professionals who help the individuals with basic needs. These often include meal preparation, housekeeping, and personal care needs. Higher functioning persons may be able to live in a home or apartment where staff only visit a few times a week. These persons generally prepare their own meals, go to work, and conduct other daily activities on their own.

Institutions. Although the trend in recent decades has been to avoid placing persons with disabilities into long-term-care institutions, this alternative is still available for persons with ASD who need intensive, constant supervision. Unlike many of the institutions years ago, today's facilities view residents as individuals with human needs and offer opportunities for recreation and simple but meaningful work.

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

Research into Causes and Treatment of Autism Spectrum Disorders

Research into the causes, the diagnosis, and the treatment of autism spectrum disorders has advanced in tandem. With new well-researched standardized diagnostic tools, ASD can be diagnosed at an early age. And with early diagnosis, the treatments found to be beneficial in recent years can be used to help the child with ASD develop to his or her greatest potential.

In the past few years, there has been public interest in a theory that suggested a link between the use of thimerosal, a mercury-based preservative used in the measles-mumps-rubella (MMR) vaccine, and autism. Although mercury is no longer found in childhood vaccines in the United States, some parents still have concerns about vaccinations. Many well-done, large-scale studies have now been done that have failed to show a link between thimerosal and autism. A panel from the Institute of Medicine is now examining these studies, including a large Danish study that concluded that there was no causal relationship between childhood vaccination using thimerosal-containing vaccines and the development of an autism spectrum disorder,[27] and a U.S. study looking at exposure to mercury, lead, and other heavy metals.

Research on the Biologic Basis of ASD

Because of its relative inaccessibility, scientists have only recently been able to study the brain systematically. But with the emergence of new brain imaging tools—computerized tomography (CT), positron emission tomography (PET), single photon emission computed tomography (SPECT), and magnetic resonance imaging

(MRI), study of the structure and the functioning of the brain can be done. With the aid of modern technology and the new availability of both normal and autism tissue samples to do postmortem studies, researchers will be able to learn much through comparative studies.

Postmortem and MRI studies have shown that many major brain structures are implicated in autism. This includes the cerebellum, cerebral cortex, limbic system, corpus callosum, basal ganglia, and brain stem.[28] Other research is focusing on the role of neurotransmitters such as serotonin, dopamine, and epinephrine.

Research into the causes of autism spectrum disorders is being fueled by other recent developments. Evidence points to genetic factors playing a prominent role in the causes for ASD. Twin and family studies have suggested an underlying genetic vulnerability to ASD.[29] To further research in this field, the Autism Genetic Resource Exchange, a project initiated by the Cure Autism Now Foundation, and aided by an NIMH grant, is recruiting genetic samples from several hundred families. Each family with more than one member diagnosed with ASD is given a 2-hour, in-home screening. With a large number of DNA samples, it is hoped that the most important genes will be found. This will enable scientists to learn what the culprit genes do and how they can go wrong.

Another exciting development is the Autism Tissue Program (http://www.brainbank.org), supported by the Autism Society of America Foundation, the Medical Investigation of Neuro-developmental Disorders (M.I.N.D.) Institute at the University of California, Davis, and the National Alliance for Autism Research. The program is aided by a grant to the Harvard Brain and Tissue Resource Center (http://www.brainbank.mclean.org), funded by the National Institute of Mental Health (NIMH) and the National

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

Institute of Neurological Disorders and Stroke (NINDS). Studies of the postmortem brain with imaging methods will help us learn why some brains are large, how the limbic system develops, and how the brain changes as it ages. Tissue samples can be stained and will show which neurotransmitters are being made in the cells and how they are transported and released to other cells. By focusing on specific brain regions and neurotransmitters, it will become easier to identify susceptibility genes.

Recent neuroimaging studies have shown that a contributing cause for autism may be abnormal brain development beginning in the infant's first months. This "growth dysregulation hypothesis" holds that the anatomical abnormalities seen in autism are caused by genetic defects in brain growth factors. It is possible that sudden, rapid head growth in an infant may be an early warning signal that will lead to early diagnosis and effective biological intervention or possible prevention of autism.[30]

For detailed information on autism spectrum disorders research, see NIMH research fact sheet, *Autism Spectrum Disorders Research* at http://www.nimh.nih.gov/publicat/autismresfact.cfm.

The Children's Health Act of 2000—What It Means to Autism Research

The Children's Health Act of 2000 was responsible for the creation of the Interagency Autism Coordinating Committee (IACC), a committee that includes the directors of five NIH institutes—the National Institute of Mental Health, the National Institute of Neurological Disorders and Stroke, the National Institute on Deafness and Other Communication Disorders (NIDCD), the National Institute of Child Health and Human Development (NICHD), and the National Institute

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

of Environmental Health Sciences (NIEHS)—as well as representatives from the Health Resource Services Administration, the National Center on Birth Defects and Developmental Disabilities (a part of the Centers for Disease Control), the Agency for Toxic Substances and Disease Registry, the Substance Abuse and Mental Health Services Administration, the Administration on Developmental Disabilities, the Centers for Medicare and Medicaid Services, the U.S. Food and Drug Administration, and the U.S. Department of Education. The Committee, instructed by the Congress to develop a 10-year agenda for autism research, introduced the plan, dubbed a "matrix" or a "roadmap," at the first Autism Summit Conference in November 2003. The roadmap indicates priorities for research for years 1 to 3, years 4 to 6, and years 7 to 10.

The five NIH institutes of the IACC have established the Studies to Advance Autism Research and Treatment (STAART) Network, composed of eight network centers. They will conduct research in the fields of developmental neurobiology, genetics, and psychopharmacology. Each center is pursuing its own particular mix of studies, but there also will be multi-site clinical trials within the STAART network.

The STAART centers are located at the following sites:

- University of North Carolina, Chapel Hill
- Yale University, Connecticut
- University of Washington, Seattle
- University of California, Los Angeles
- Mount Sinai Medical School, New York
- Kennedy Krieger Institute, Maryland
- Boston University, Massachusetts
- University of Rochester, New York

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

A data coordination center will analyze the data generated by both the STAART network and the Collaborative Programs of Excellence in Autism (CPEA). This latter program, funded by the NICHD and the NIDCD Network on the Neurobiology and Genetics of Autism, consists of 10 sites. The CPEA is at present studying the world's largest group of well-diagnosed individuals with autism characterized by genetic and developmental profiles.

The CPEA centers are located at:

- Boston University, Massachusetts
- University of California, Davis
- University of California, Irvine
- University of California, Los Angeles
- Yale University, Connecticut
- University of Washington, Seattle
- University of Rochester, New York
- University of Texas, Houston
- University of Pittsburgh, Pennsylvania
- University of Utah, Salt Lake City

The NIEHS has programs (http://www.niehs.nih.gov/translat/children/ctr-desc.htm) at:

- Center for Childhood Neurotoxicology and Assessment, University of Medicine & Dentistry, New Jersey
- The Center for the Study of Environmental Factors in the Etiology of Autism, University of California, Davis

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

Addendum to Autism Spectrum Disorders

January 2007

This addendum to the booklet *Autism Spectrum Disorders* was prepared to clarify information contained in the booklet; and to provide updated information on the prevalence of autism spectrum disorders. This addendum also applies to the Autism Spectrum Disorders Web page document.

Prevalence

In 2003 - the most recent government study on the rate of autism - the Centers for Disease Control (CDC) found that the rate is higher than the rates found from studies conducted in the United States during the 1980s and early 1990s. This study was consistent with the rate found in other more recent studies. Debate continues about whether this represents a true increase in prevalence. Changes in the criteria used to diagnose autism, along with increased recognition of the disorder by professionals and the public may all be contributing factors. Nonetheless, it is clear that more children are being diagnosed with an ASD than ever before.

Data from the CDC's Atlanta-based program found the rate of autism spectrum disorder was 3.4 per 1,000 for children 3 to 10 years of age. Summarizing this and several other major studies on autism prevalence, CDC estimates that 2–6 per 1,000 (from 1 in 500 to 1 in 166) children have an ASD. Compared to the prevalence of other childhood conditions, this rate is lower than the rate of mental retardation (9.7 per 1,000 children), but higher than the rates for cerebral palsy (2.8 per 1,000 children), hearing loss (1.1 per 1,000 children), and vision impairment (0.9 per 1,000 children).[1] For additional data, please visit the CDC Web site.

Fragile X

The original booklet and Web page contains the following statement about inheriting Fragile X Syndrome:

> "For an unknown reason, if a child with ASD also has Fragile X, there is a one-in-two chance that boys born to the same parents will have the syndrome.[2] Other members of the family who may be contemplating having a child may also wish to be checked for the syndrome."

A distinction can be made between a father's and mother's ability to pass along to a daughter or son the altered gene on the X chromosome that is linked to fragile X syndrome. Because both males (XY) and females (XX) have at least one X chromosome, both can pass on the mutated gene to their children.

A father with the altered gene for Fragile X on his X chromosome will only pass that gene on to his daughters. He passes a Y chromosome on to his sons, which doesn't transmit the condition. Therefore, if the father has the altered gene on his X chromosome, but the mother's X

---

[1] Yeargin-Allsopp M, Rice C, Karapurkar T, Doernberg N, Boyle C, Murphy C. Prevalence of Autism in a US Metropolitan Area. *The Journal of the American Medical Association.*. 2003 Jan 1;289(1):49-55.

chromosomes are normal, all of the couple's daughters would have the altered gene for Fragile X, while none of their sons would have the mutated gene.

Because mothers pass on only X chromosomes to their children, if the mother has the altered gene for Fragile X, she can pass that gene to either her sons or her daughters. If the mother has the mutated gene on one X chromosome and has one normal X chromosome, and the father has no genetic mutations, all the children have a 50-50 chance of inheriting the mutated gene.

The odds noted here apply to each child the parents have.[3]
In terms of prevalence, the latest statistics are consistent in showing that 5% of people with autism are affected by fragile X and 10% to 15% of those with fragile X show autistic traits.

Medications

On October 6, 2006 the U.S. Food and Drug Administration (FDA) approved risperidone (generic name) or Risperdal (brand name) for the symptomatic treatment of irritability in autistic children and adolescents ages 5 to 16. The approval is the first for the use of a drug to treat behaviors associated with autism in children. These behaviors are included under the general heading of irritability, and include aggression, deliberate self-injury and temper tantrums.

Olanzapine (Zyprexa) and other antipsychotic medications are used "off-label" for the treatment of aggression and other serious behavioral disturbances in children, including children with autism. Off-label means a doctor will prescribe a medication to treat a disorder or in an age group that is not included among those approved by the FDA.

Other medications are used to address symptoms or other disorders in children with autism. Fluoxetine (Prozac) and sertraline (Zoloft) are approved by the FDA for children age 7 and older with obsessive-compulsive disorder. Fluoxetine is also approved for children age 8 and older for the treatment of depression.

Fluoxetine and sertraline are antidepressants known as selective serotonin reuptake inhibitors (SSRIs). Despite the relative safety and popularity of SSRIs and other antidepressants, some studies have suggested that they may have unintentional effects on some people, especially adolescents and young adults. In 2004, after a thorough review of data, the Food and Drug Administration (FDA) adopted a "black box" warning label on all antidepressant medications to alert the public about the potential increased risk of suicidal thinking or attempts in children and adolescents taking antidepressants. In 2007, the agency extended the warning to include young adults up to age 25. A "black box" warning is the most serious type of warning on prescription drug labeling. The warning emphasizes that children, adolescents and young adults taking antidepressants should be closely monitored, especially during the initial weeks of treatment, for any worsening depression, suicidal thinking or behavior, or any unusual changes in behavior such as sleeplessness, agitation, or withdrawal from normal social situations.

Disorders/Vaccinations

The Institute of Medicine (IOM) conducted a thorough review on the issue of a link between thimerosal (a mercury based preservative that is no longer used in vaccinations) and autism. The final report from IOM, Immunization Safety Review: Vaccines and Autism, released in May 2004, stated that the committee did not find a link.

Until 1999, vaccines given to infants to protect them against diphtheria, tetanus, pertussis, *Haemophilus influenzae* type b (Hib), and Hepatitis B contained thimerosal as a preservative. Today, with the exception of some flu vaccines, none of the vaccines used in the U.S. to protect preschool aged children against 12 infectious diseases contain thimerosal as a preservative. The MMR vaccine does not and never did contain thimerosal. Varicella (chickenpox), inactivated polio (IPV), and pneumococcal conjugate vaccines have also never contained thimerosal.

A U.S. study looking at environmental factors including exposure to mercury, lead and other heavy metals is ongoing.

SUPPORT Neuroimaging secondary update — Susan Hintz
NRN Steering Committee meeting June 2009

Enrollment/Process/Follow-up update

- 16 sites have participated in SUPPORT Neuroimaging secondary
  - 661 patients were enrolled in the SUPPORT Neuroimaging secondary
    - **533 patients** have completed neuroimaging including successful 35-42 week MRI (as of 5/31/09 monthly report)
      - Of 127 patients enrolled who do not have MRI:
        - 87 patients died before MRI
        - 10 with MRI01 not yet complete
        - 30 with other issues including technical/availability (4), attempted but movement or uncooperative (5), patient discharged or transferred prior to MRI, or missed (7), clinically unstable (6), withdrew consent (4), other (4)
  - 18-22 month follow-up so far -
    - **196 patients** in this cohort with near-term MRI's who survived to discharge will have 18-22 month follow-up windows **closed** as of 7/1/09
      - **177 have completed 18-22 month visit**
        - 5 formally reported lost to follow-up;
        - 2 are reported going to be followed at another center;
        - 7 have not been seen yet
        - 5 died after discharge
          - **177/191 = ~93% follow-up rate among survivors**

Neuroimaging

- Many thanks to the site coordinators for their enormous efforts in enrolling, following through with all neuroimaging, and providing readable imaging!
- CUS central reading –
  - First 2-day central reading May 9 & 10; ~40% of CUS completed
  - Second (and hopefully final) 2-day CUS central reading August 23 & 24
- MRI central reading
  - Dr. Barnes currently reading; also, central reading Stanford on June 29th
  - 2nd reader for random sample of the MRI's to establish reliability
    - White matter injury summary classifications (based on previously published criteria from Miller, Inder) with previously reported reliability data
    - Preliminary calculations (Abhik Das) suggests ~80-100 MRI's would need to be read.
- **THANK YOU to RTI and NICHD (especially Meg, Kris, Carolyn, Jamie, and Rose!) for their enormous help with this huge job!**

SUPPORT Neuroimaging: Extended Follow-Up

- Separate update later this afternoon

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

To: Wilson, Leslie Dawn; Higgins, Rosemary (NIH/NICHD) [E]; Poindexter, Brenda B; Dusick, Anna M.; Hamer, Faithe Angeline
Subject: RE: SUPPORT
Date: Monday, June 22, 2009 11:37:26 AM

Hi Leslie,

To answer your question about infant (b) (6) , the infant currently has SUPP10 question "Final ROP status determined at 18M Follow Up?" answered as No. However, the infant has not yet reached 18 months adjusted age. Unless you are sure that there is no chance of obtaining ROP status at FU, this question should be left blank until the infant is old enough to have the FU visit. Leaving the question blank will prompt us to send you a reminder to obtain ROP information when the FU window opens. If the question is answered No prematurely then you will not receive that reminder. If for some reason you are sure that there is no chance of obtaining ROP status at the FU visit, then you can leave the question answered No but please enter an F5 to explain why the question was answered before the infant reached 18 months adjusted age. Otherwise, please change the answer from No to missing.

Also, regarding infant (b) (6) , not sure what you mean by "a week of his earlier stay is missing. We are waiting to see if it scans in when he is discharged." However, I think you can wait until the infant is discharged to enter the data on the NG07. In the meantime, you will continue to receive reminders until the data are entered.

Thanks, and let me know if you have any other questions.

Marie

Hi,
We are missing a few SUPPORT outcomes. Recruitment is finished in the trial and we are trying to get all of the needed information into the DMS in a timely manner. Please let us know how you are doing.

Thanks for all the hard work!!
Rose

Hello Everyone
Congratulations on a job very well done!!
Marie has prepared the following summary for our meeting

SUPPORT Update 6/19/2009

Total enrollment of 1317 was completed in February 2009. The primary outcomes of BPD/death and ROP/death are still unknown for 14 and 140 infants, respectively.

	ROP/death		
BPD/death	**Known**	**Unknown**	**Total**
Known	1172	131	1303
Unknown	5	9	14
Total	1177	140	1317

Infants with known outcomes for BPD/death and ROP/death

The last SUPPORT infant reached 36 weeks PMA in late May, so we should have complete data on the BPD outcome shortly. Historically, by 55 weeks PMA we have known ROP status for 100% of the infants with an adverse outcome and about 92% of the infants with a positive outcome. The last SUPPORT infant will reach 55 weeks PMA at the end of September.

To date, 778 (59%) of SUPPORT infants have a known outcome for NDI/death at 18-22 months adjusted age. The last follow up window will open in December 2010 and will close in April 2011.

She will try to get us some overall oximeter data if possible

I will be starting to develop the manuscript
We are planning a visit to RTI and Wally will join us there at the end of August – hopefully when we can close the neonatal endpoints of ROP/BPD. We should have the BPD data within a few weeks
The plan is to develop 2 manuscripts –
CPAP vs Surfactant
High vs Lower SpO2

I suspect that we will be ready with the first within 2 months
And the second in 3 months
We would obviously submit as soon as they are ready – Probably NEJM

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

We need to complete the follow-up and we are well on the way with almost 60% of those outcomes available
The very first manuscript will be the consent manuscript which is now circulating to the authors. I have attached for your comments

Points for discussion:

1. Where should the data be presented??

It will be ready well ahead of PAS.
There will probably be new data for PAS – Secondaries etc

2. Need status reports for all secondaries
3. Continue to get all final infant data, especially ROP data, and complete follow-up
4. Any additional bisuness??

Safe travels
Neil

ABSTRACT

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

Objective:

This study was designed to quantify the time and effort involved in enrolling infants into the NICHD Neonatal Research Network (NRN) SUPPORT trial and to better predict the time required for recruitment into a complex interventional trial requiring antenatal consent.

Design/Methods:

A data form was designed to obtain information about eligible mothers who were available and approached at each center, to determine who approached them, how often they were approached, the duration of each contact, whether consent was obtained and if the infant(s) was enrolled. Infants born at Network centers who delivered in the SUPPORT window were entered into the NRN Generic Database. These data were used to identify infants who were eligible but not approached or enrolled.

Results

2828 women were identified at 18 collaborating units as being at risk for premature delivery at 24 to 27 6/7 wks GA between October 2005 and February 2009. 2228 were approached for informed consent. The most common reasons for not approaching mothers included fetal abnormalities, active labor and language barriers. A study coordinator/research nurse made 75% of all approaches. For 77% of those approached, consent was attempted < 3 times. (Overall mean 2.0 +/- 1.2). Estimated GA at time of screening was not different for those who consented versus those who did not. Seven percent of those approached were identified as having been approached for another maternal study and 1% for another neonatal study. Of the 2228 mothers approached, 1217 gave consent. Five hundred seventy-eight of those consented delivered 655 infants within the study window, and 535 of these delivered 610 infants that were enrolled. Forty-five consented infants born in the GA window were not enrolled. Only 19% of screened women delivered infants subsequently enrolled in the study. There was a significant relationship between performing a neonatal consult and obtaining consent ($p<.0001$). Centers that were also NICHD Maternal Fetal Medicine network centers enrolled at a higher rate and were more likely to use < 30 minutes to obtain consent. A significantly higher proportion of infants who delivered in the

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

study window but were not enrolled in SUPPORT had no exposure to antenatal steroids compared with infants who were enrolled. (15.7 vs. 3.8% p<.0001). The difference in lack of antenatal steroid exposure was even greater for the infants of approached vs. non-approached women (3.4 vs. 20.3%, p<.0001).

Conclusions:

In a complex interventional trial of preterm infants requiring antenatal consent, more than 5 women were identified as likely to deliver a baby in the window for each one who delivered an infant enrolled in the trial. Extrapolating these data to the entire SUPPORT trial suggests that over 2400 hours were spent screening greater than 6000 women to enroll 1317 infants in the trial. The differences between enrolled versus non-enrolled infants highlight the difficulties in attempting to recruit a representative population for prospective trials requiring antenatal consent.

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

Introduction:

The process of informed consent was established to ensure that subjects enrolled in research trials were appropriately informed as to the risks and benefits of the trial, came to the trial voluntarily, and represented an accurate cross-section of all subjects who would potentially receive benefit from or undergo the risks of the studied intervention. Traditionally, this consent is obtained directly from the subject when they are in condition to understand and participate in the process. In conducting trials on infants who will receive an intervention at or near the time of birth, the process requires approaching families prior to delivery to provide consent for their infant(s).

Funding for clinical trials sponsored by federal agencies and industry is often based on a model of capitation where a site is paid based on the number of subjects enrolled and some pre-calculated screening time. However, because prospective data comparing the number of families who are approached in the antenatal period to the number of infants who are actually enrolled have not previously been available, the current model may not adequately account for time spent by study staff to screen, approach and enroll all eligible subjects.

Early enrollment in the Surfactant Positive Airway Pressure and Pulse Oximetry Trial in Extremely Low Birth Weight Infants (SUPPORT) demonstrated that antenatal screening and consent were labor intensive and that actual patient enrollment numbers differed significantly from the screening and consent rates. Thus, this secondary study was designed to evaluate the antenatal screening and consent process to determine the factors that contribute to successful enrollment of patients in a complex trial conducted by an experienced multi-center trials network.

Methods:

This is a prospective cohort study of the antenatal consenting practices of research personnel in the multi-center Neonatal Research Network (NRN) funded by the Eunice Kennedy Shriver National Institute of Child Health and Human Development (NICHD). Data for this study were collected during the

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

last half of the NRN SUPPORT trial. The SUPPORT trial was designed to compare the use of early CPAP initiated in the delivery room to early intubation and surfactant given within the first hour of life, and to compare randomization to 2 different target SpO2 ranges during receipt of supplemental oxygen up to 36 weeks post menstrual age (PMA). Eligible infants were 24 0/7ths to 27 6/7ths weeks gestational age (GA) without known malformation for whom full postnatal treatment was expected.

Eligible subjects for the antenatal consent secondary study were those women who the Obstetrical/Perinatal staff felt were likely to deliver in the SUPPORT gestational age window. Clinical data were collected by trained research coordinators, and all analyses were performed at a central data coordinating center (DCC) (RTI International, Research Triangle Park, NC). Research staff self-reported study data using a one page data collection form. If the parent(s) were not approached for consent, the reason they were not approached was recorded. If they were approached, the staff recorded the total number of times the parent(s) were approached, the number of such attempts which were made by the research coordinator/RN, and whether OB permission was obtained to approach for antenatal consent. As a neonatal consult is often performed on this population, staff recorded whether a consult was performed, whether the consent was discussed during the consultation, and whether consent was obtained at the time of the consult. In some centers the Institutional Review Board required a consult be completed prior to consent, so this was also recorded. Women who were approached for SUPPORT were asked if they were approached for participation in any other studies either for themselves or their infants. Finally, the study staff was asked to estimate the time required to obtain a decision regarding consent.

Data were collected at each of the 18 NICHD NRN centers until fifty mothers had delivered within the window at the center. Data forms were keyed by the centers and transmitted electronically to the DCC. Infants born at Network centers who delivered in the SUPPORT window were entered into the NRN Generic Database (GDB) which, before 2008, collected delivery and demographic data on infants between 401 and 1500g inclusive birth weight who were inborn at NRN centers or admitted to

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

the NICU within 14 days of age. Beginning in 2008, the database collected infants who were 1) inborn and between 401 grams and 1000 grams inclusive birth weight and/or 2) inborn and between 22 0/7 and 28 6/7 weeks (<29 weeks) inclusive gestational age. GDB data were used to evaluate whether infants enrolled in the SUPPORT trial represented the entire eligible Network population.

To determine the representativeness of the population enrolled in the SUPPORT trial, data from the GDB were obtained for those infants born at NRN centers during the period of SUPPORT trial enrollment who qualified to participate in SUPPORT. This information included whether prenatal care was obtained, the use of antenatal steroids and demographic data. These data were compared for infants who were or were not enrolled in SUPPORT to assess whether the trial had enrolled a representative sample of the available population. In addition, comparisons were made between eligible infants whose mothers were or were not approached for SUPPORT.

We performed bivariate statistical analyses using Chi-Square and Student's t-tests. All statistical analyses were performed using SAS version 9.1.3 (SAS Institute Inc., Cary, NC). A p value of less than 0.05 was considered statistically significant. This trial was approved by the Institutional Review Boards of all participating centers as well as that of RTI.

Results

Between October 2005 and February 2009, a total of 2828 women were identified at 18 NRN centers as being at risk for delivering a premature infant between 24 to 27 6/7 wks GA and otherwise eligible for participation in the SUPPORT trial. Two additional NRN centers did not participate in the antenatal consent trial and 4 who did participate did not identify 50 eligible women between the start of data collection for the antenatal consent study and the end of the SUPPORT trial. Four centers identified more than 50 women (mean 82) before they were informed that they could stop collecting data. All data collected by participating centers have been included in this analysis. Results of an analysis using only the first 50 women from the centers that over-enrolled were not significantly different. Data for screening, enrollment and consent by center are presented in Figure 1.

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

2228 women were approached for informed consent. The two most frequent reasons for not attempting to obtain a consent were early discharge and a lack of time prior to delivery (Table 2). Common choices within the "other" category in the table were early discharge, the ability of the mother to give consent, fetal abnormalities, and language barriers that made informed consent impossible. Reasons mothers were considered unable to give consent included being in active labor, being too young, and having either a mental or physical health issue which precluded them being approached. A study coordinator or research RN made 75% of all approaches. For 77% of those women approached, consent was attempted < 3 times. (Overall mean 2.0 +/- 1.2). The frequency of approaches ranged from 1 (n=900) to 11 (n=2) times. The median time spent to obtain a decision regarding consent was less than 1 hour regardless of the decision. The estimated GA at time of screening was not significantly different for those who consented versus those who did not. Of the 2228 mothers approached, 1217 gave consent, 578 subsequently delivered 655 infants within the SUPPORT study window, and 535 delivered 610 infants who were enrolled (Figure 2). Forty-five consented infants born in the GA window (7%) were not enrolled, usually due to lack of staffing, equipment, or time. Only 19% of those mothers screened delivered infants who were subsequently enrolled in the study. A neonatal consult was performed in 70% of cases. There was a significant relationship between performing a neonatal consult and obtaining consent ($p < .0001$), but consent was only obtained during the consult 12% of the time. Centers that were also NICHD Maternal Fetal Medicine network centers enrolled at a higher rate and were more likely to require less than 30 minutes to obtain a consent decision. The median time spent to obtain a decision regarding consent for all centers was less than 1 hour regardless of the decision.

Infants of non-approached and approached mothers were different in several important ways as shown in Table 1. Infants of approached mothers were more likely to be non-Hispanic white ($p<0.0001$); the mothers were more likely to be older ($p=0.0210$) and to have a high school education ($p<0.0001$), medical insurance ($p<0.0001$), and at least one PNC visit ($p<0.0001$). A significantly higher proportion of infants born in the study window whose mothers were not approached for SUPPORT had no exposure to

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

antenatal steroids compared with infants whose mothers were approached (20.3% vs 3.4%, p<.0001). Maternal gravidity and parity were not significantly different between these groups.

Infants who were enrolled in SUPPORT and those who were not enrolled were also significantly different. Non-enrolled infants had mothers who were significantly less likely to have insurance (p=0.0011) and to have received prenatal care (p=0.0039), and were over 4 times more likely to have gone without antenatal steroids (15.7% vs. 3.8%, p<0.0001) (Table 2).

Discussion:

To our knowledge this is the first neonatal study to evaluate the time and work required to approach and obtain consent from parents for the enrollment of their premature infants who at the time of the consent were not yet born. Our results reveal that 5 families needed to be identified and screened for every one that had an infant successfully enrolled. Only 47% of women from whom consent was obtained went on to deliver infants in the study window. Though the time needed to obtain consent was collected as a discrete variable, we found that the median was between 30 minutes and 1 hour. Multiplying these bounds by the number of women approached for each enrolled infant (3.7) yields a value for coordinator time required to obtain an enrolled infant at between 1.8 and 3.7 hours. This includes time spent approaching women who did not consent and consenting women who did not deliver in the window. It does not account for time spent screening women who were not approached for consent.

Morley et al reviewed parental willingness to participate in multiple trials in the neonatal period and found that most (74%) were willing to allow their baby to participate in multiple trials. [1] We had concerns that the burden of being approached for multiple trials, especially since 5 centers belonged to a second maternal/fetal research network, would affect the enrollment in SUPPORT. We found that only 8% of women had been approached for another trial at the time of the SUPPORT consent discussion, probably because it was an antenatal consent and the window was early in gestation.

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

Because of the unique attributes of the NRN, we were able to obtain demographic data from the GDB for infants who were delivered in the SUPPORT window but were not enrolled in the study. Thus, we were able to compare infants who were vs. were not enrolled and those whose mothers were vs. were not approached. These groups differed in a number of significant areas. Most importantly, infants born to women who were not approached for consent were almost 6 times more likely not to have been exposed to antenatal steroids, an intervention known to be associated with better short and longer term outcomes for preterm infants. [2] They were also more likely to be more immature and their mothers were significantly less likely to have insurance and to have received prenatal care.

In a review of NIH funded interventional randomized controlled trials, Charlson and Horwitz found that only half such trials kept any data on subjects who were eligible but not enrolled, and for those trials which did keep data only 27% of eligible non-enrolled subjects were a result of subject refusal.[3] The Consolidated Standards for Reporting of Trials (CONSORT) is a document created with the intent of standardizing items reported in trial publications, including a checklist for necessary items and a flow chart of participants.[4,5] The standards require the quantifying of eligible populations but make no such requirement for identifying the demographics of this group or its similarity to the enrolled or consented populations. Research from the California Department of Health Services reviewed the effect of the introduction of tandem Mass Spectrometry (MS/MS) to the California Newborn Screening program.[6] This involved another test on an already collected blood spot, for which it was decided informed consent was necessary. They found that the burden of adding informed consent to the screening process resulted in only 50% of infants being screened for the new test. Twenty one percent of participating hospitals did not offer the screening because of the burden of providing informed consent. It is very possible that failure rates for enrollment of infants in trials that require consent in the antenatal period is much higher than is currently believed. Following the CONSORT standards in all antenatal consent trials, both consented and waived, and obtaining basic demographic information for

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

all eligible infants will help us understand whether similar reduction in enrollment occurs when the burden of consent is added to these trials and whether the enrolled infants are representative of the true eligible population.

Blinding and randomization have always been the benchmarks for protecting trials from bias. Investigators have shown that trials in which allocation to a study group is well concealed more accurately reflect the true study effect than those not well concealed.[7] However, these controls only protect the trial from internal bias. Manning and Silverman have voiced concerns about selection bias, stating that a disproportionate number of vulnerable and deprived families are involved in clinical research.[8,9] Harth and Thong questioned parents who had volunteered in an asthma trial in Australia and concluded that volunteering parents were "significantly more socially disadvantaged and emotionally vulnerable." [10] In a study of recruitment and retention of premature infants into an early intervention program, Constantine et al found significant enrollment bias in this direction related to race, weight and site. [11] Zupancic et al. analyzed three postnatal trials in Canada, which has universal healthcare and other social benefits, and found no significant socio-economic difference between those who consented when compared with those who did not.[12] Mitchell and Kline, on the other hand, showed a significantly greater proportion of African-Americans, uninsured patients, and Medicaid recipients in the non-participant group in a minimal risk emergency department study.[13] Aagaard-Tillery and the NICHD Maternal Fetal Medicine (MFM) network found that blacks and Hispanics were significantly less likely to allow use of their genetic samples for future studies.[14]

Glassberg, Luce and Matthay analyzed the screening and enrollment of a trial of acute lung injury in two San Francisco hospitals, one an academic referral center and the other the public hospital for the city. [15] The percentage of screened infants enrolled was nearly 3 times higher in the academic center, a statistically significant difference ($p<.0001$). All of the centers in our trial were academic centers, but many included a relationship with a non-academic center. With the exception of Zupancic, which took place in a country with universal healthcare, all of these reports of selection bias point

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

toward the need to find a better method of enrolling truly representative populations for trials evaluating better practices.

The bias in our analysis would suggest that under privileged subjects were less likely to participate. Because this trial enrolled subjects from all socio-economic groups at 18 academic centers with long-term randomized trial experience, it is not likely that the bias involved represents an intention to include or not include any group. The logical conclusion is that the many subjects who ended up excluded from this trial, despite the significant time and effort spent by the coordinators to include them, represent a failure of, or an innate problem with, the antenatal-consent process itself. Our observations, along with previous experience in a trial of a delivery room intervention[16], suggest that it is appropriate from an ethical perspective to allow trials that compare standard of care interventions to waive the consent process until after birth. This would ensure that the infants enrolled in such a trial do not differ significantly from the overall eligible population and insure the generalizability of the results.

Conclusion

Our prospective analysis of the process of antenatal consent enrollment in the NICHD Neonatal Research Network SUPPORT trial has shown that antenatal screening and consent are labor intensive, that actual patient enrollment numbers may be significantly lower than screening and consent rates, and that the population studied may not be representative of the total eligible population. In this complex interventional trial of preterm infants, nearly 5 women were identified as likely to deliver a baby in the window for every infant enrolled in the trial. Antenatal steroid use was significantly higher among infants enrolled in the SUPPORT study compared to those who were eligible but not enrolled, with a similar difference between infants born to approached and non-approached women. Along with quantifying the time and expense of antenatal consent, these observations point out the difficulties in attempting to recruit a representative population for prospective trials requiring antenatal consent and suggest that greater use of waiver of consent for trials that are low risk may be appropriate for future studies.

ABSTRACT

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

Objective:

This study was designed to quantify the time and effort involved in enrolling infants into the NICHD Neonatal Research Network (NRN) SUPPORT trial and to better predict the time required for recruitment into a complex interventional trial requiring antenatal consent.

Design/Methods:

A data form was designed to obtain information about eligible mothers who were available and approached at each center, to determine who approached them, how often they were approached, the duration of each contact, whether consent was obtained and if the infant(s) was enrolled. Infants born at Network centers who delivered in the SUPPORT window were entered into the NRN Generic Database. These data were used to identify infants who were eligible but not approached or enrolled.

Results

2828 women were identified at 18 collaborating units as being at risk for premature delivery at 24 to 27 6/7 wks GA between October 2005 and February 2009. 2228 were approached for informed consent. The most common reasons for not approaching mothers included fetal abnormalities, active labor and language barriers. A study coordinator/research nurse made 75% of all approaches. For 77% of those approached, consent was attempted < 3 times. (Overall mean 2.0 +/- 1.2). Estimated GA at time of screening was not different for those who consented versus those who did not. Seven percent of those approached were identified as having been approached for another maternal study and 1% for another neonatal study. Of the 2228 mothers approached, 1217 gave consent. Five hundred seventy-eight of those consented delivered 655 infants within the study window, and 535 of these delivered 610 infants that were enrolled. Forty-five consented infants born in the GA window were not enrolled. Only 19% of screened women delivered infants subsequently enrolled in the study. There was a significant relationship between performing a neonatal consult and obtaining consent ($p<.0001$). Centers that were also NICHD Maternal Fetal Medicine network centers enrolled at a higher rate and were more likely to use < 30 minutes to obtain consent. A significantly higher proportion of infants who delivered in the

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

study window but were not enrolled in SUPPORT had no exposure to antenatal steroids compared with infants who were enrolled. (15.7 vs. 3.8% p<.0001). The difference in lack of antenatal steroid exposure was even greater for the infants of approached vs. non-approached women (3.4 vs. 20.3%, p<.0001).

Conclusions:

In a complex interventional trial of preterm infants requiring antenatal consent, more than 5 women were identified as likely to deliver a baby in the window for each one who delivered an infant enrolled in the trial. Extrapolating these data to the entire SUPPORT trial suggests that over 2400 hours were spent screening greater than 6000 women to enroll 1317 infants in the trial. The differences between enrolled versus non-enrolled infants highlight the difficulties in attempting to recruit a representative population for prospective trials requiring antenatal consent.

Introduction:

The process of informed consent was established to ensure that subjects enrolled in research trials were appropriately informed as to the risks and benefits of the trial, came to the trial voluntarily, and represented an accurate cross-section of all subjects who would potentially receive benefit from or undergo the risks of the studied intervention. Traditionally, this consent is obtained directly from the subject when they are in condition to understand and participate in the process. In conducting trials on infants who will receive an intervention at or near the time of birth, the process requires approaching families prior to delivery to provide consent for their infant(s).

Funding for clinical trials sponsored by federal agencies and industry is often based on a model of capitation where a site is paid based on the number of subjects enrolled and some pre-calculated screening time. However, because prospective data comparing the number of families who are approached in the antenatal period to the number of infants who are actually enrolled have not previously been available, the current model may not adequately account for time spent by study staff to screen, approach and enroll all eligible subjects.

Early enrollment in the Surfactant Positive Airway Pressure and Pulse Oximetry Trial in Extremely Low Birth Weight Infants (SUPPORT) demonstrated that antenatal screening and consent were labor intensive and that actual patient enrollment numbers differed significantly from the screening and consent rates. Thus, this secondary study was designed to evaluate the antenatal screening and consent process to determine the factors that contribute to successful enrollment of patients in a complex trial conducted by an experienced multi-center trials network.

Methods:

This is a prospective cohort study of the antenatal consenting practices of research personnel in the multi-center Neonatal Research Network (NRN) funded by the Eunice Kennedy Shriver National Institute of Child Health and Human Development (NICHD). Data for this study were collected during the

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

last half of the NRN SUPPORT trial. The SUPPORT trial was designed to compare the use of early CPAP initiated in the delivery room to early intubation and surfactant given within the first hour of life, and to compare randomization to 2 different target SpO2 ranges during receipt of supplemental oxygen up to 36 weeks post menstrual age (PMA). Eligible infants were 24 0/7ths to 27 6/7ths weeks gestational age (GA) without known malformation for whom full postnatal treatment was expected.

Eligible subjects for the antenatal consent secondary study were those women who the Obstetrical/Perinatal staff felt were likely to deliver in the SUPPORT gestational age window. Clinical data were collected by trained research coordinators, and all analyses were performed at a central data coordinating center (DCC) (RTI International, Research Triangle Park, NC). Research staff self-reported study data using a one page data collection form. If the parent(s) were not approached for consent, the reason they were not approached was recorded. If they were approached, the staff recorded the total number of times the parent(s) were approached, the number of such attempts which were made by the research coordinator/RN, and whether OB permission was obtained to approach for antenatal consent. As a neonatal consult is often performed on this population, staff recorded whether a consult was performed, whether the consent was discussed during the consultation, and whether consent was obtained at the time of the consult. In some centers the Institutional Review Board required a consult be completed prior to consent, so this was also recorded. Women who were approached for SUPPORT were asked if they were approached for participation in any other studies either for themselves or their infants. Finally, the study staff was asked to estimate the time required to obtain a decision regarding consent.

Data were collected at each of the 18 NICHD NRN centers until fifty mothers had delivered within the window at the center. Data forms were keyed by the centers and transmitted electronically to the DCC. Infants born at Network centers who delivered in the SUPPORT window were entered into the NRN Generic Database (GDB) which, before 2008, collected delivery and demographic data on infants between 401 and 1500g inclusive birth weight who were inborn at NRN centers or admitted to

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

the NICU within 14 days of age. Beginning in 2008, the database collected infants who were 1) inborn and between 401 grams and 1000 grams inclusive birth weight and/or 2) inborn and between 22 0/7 and 28 6/7 weeks (<29 weeks) inclusive gestational age. GDB data were used to evaluate whether infants enrolled in the SUPPORT trial represented the entire eligible Network population.

To determine the representativeness of the population enrolled in the SUPPORT trial, data from the GDB were obtained for those infants born at NRN centers during the period of SUPPORT trial enrollment who qualified to participate in SUPPORT. This information included whether prenatal care was obtained, the use of antenatal steroids and demographic data. These data were compared for infants who were or were not enrolled in SUPPORT to assess whether the trial had enrolled a representative sample of the available population. In addition, comparisons were made between eligible infants whose mothers were or were not approached for SUPPORT.

We performed bivariate statistical analyses using Chi-Square and Student's t-tests. All statistical analyses were performed using SAS version 9.1.3 (SAS Institute Inc., Cary, NC). A p value of less than 0.05 was considered statistically significant. This trial was approved by the Institutional Review Boards of all participating centers as well as that of RTI.

Results

Between October 2005 and February 2009, a total of 2828 women were identified at 18 NRN centers as being at risk for delivering a premature infant between 24 to 27 6/7 wks GA and otherwise eligible for participation in the SUPPORT trial. Two additional NRN centers did not participate in the antenatal consent trial and 4 who did participate did not identify 50 eligible women between the start of data collection for the antenatal consent study and the end of the SUPPORT trial. Four centers identified more than 50 women (mean 82) before they were informed that they could stop collecting data. All data collected by participating centers have been included in this analysis. Results of an analysis using only the first 50 women from the centers that over-enrolled were not significantly different. Data for screening, enrollment and consent by center are presented in Figure 1.

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

2228 women were approached for informed consent. The two most frequent reasons for not attempting to obtain a consent were early discharge and a lack of time prior to delivery (Table 2). Common choices within the "other" category in the table were early discharge, the ability of the mother to give consent, fetal abnormalities, and language barriers that made informed consent impossible. Reasons mothers were considered unable to give consent included being in active labor, being too young, and having either a mental or physical health issue which precluded them being approached. A study coordinator or research RN made 75% of all approaches. For 77% of those women approached, consent was attempted < 3 times. (Overall mean 2.0 +/- 1.2). The frequency of approaches ranged from 1 (n=900) to 11 (n=2) times. The median time spent to obtain a decision regarding consent was less than 1 hour regardless of the decision. The estimated GA at time of screening was not significantly different for those who consented versus those who did not. Of the 2228 mothers approached, 1217 gave consent, 578 subsequently delivered 655 infants within the SUPPORT study window, and 535 delivered 610 infants who were enrolled (Figure 2). Forty-five consented infants born in the GA window (7%) were not enrolled, usually due to lack of staffing, equipment, or time. Only 19% of those mothers screened delivered infants who were subsequently enrolled in the study. A neonatal consult was performed in 70% of cases. There was a significant relationship between performing a neonatal consult and obtaining consent ($p < .0001$), but consent was only obtained during the consult 12% of the time. Centers that were also NICHD Maternal Fetal Medicine network centers enrolled at a higher rate and were more likely to require less than 30 minutes to obtain a consent decision. The median time spent to obtain a decision regarding consent for all centers was less than 1 hour regardless of the decision.

Infants of non-approached and approached mothers were different in several important ways as shown in Table 1. Infants of approached mothers were more likely to be non-Hispanic white ($p<0.0001$); the mothers were more likely to be older ($p=0.0210$) and to have a high school education ($p<0.0001$), medical insurance ($p<0.0001$), and at least one PNC visit ($p<0.0001$). A significantly higher proportion of infants born in the study window whose mothers were not approached for SUPPORT had no exposure to

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

antenatal steroids compared with infants whose mothers were approached (20.3% vs 3.4%, p<.0001). Maternal gravidity and parity were not significantly different between these groups.

Infants who were enrolled in SUPPORT and those who were not enrolled were also significantly different. Non-enrolled infants had mothers who were significantly less likely to have insurance (p=0.0011) and to have received prenatal care (p=0.0039), and were over 4 times more likely to have gone without antenatal steroids (15.7% vs. 3.8%, p<0.0001) (Table 2).

Discussion:

To our knowledge this is the first neonatal study to evaluate the time and work required to approach and obtain consent from parents for the enrollment of their premature infants who at the time of the consent were not yet born. Our results reveal that 5 families needed to be identified and screened for every one that had an infant successfully enrolled. Only 47% of women from whom consent was obtained went on to deliver infants in the study window. Though the time needed to obtain consent was collected as a discrete variable, we found that the median was between 30 minutes and 1 hour. Multiplying these bounds by the number of women approached for each enrolled infant (3.7) yields a value for coordinator time required to obtain an enrolled infant at between 1.8 and 3.7 hours. This includes time spent approaching women who did not consent and consenting women who did not deliver in the window. It does not account for time spent screening women who were not approached for consent.

Morley et al reviewed parental willingness to participate in multiple trials in the neonatal period and found that most (74%) were willing to allow their baby to participate in multiple trials. [1] We had concerns that the burden of being approached for multiple trials, especially since 5 centers belonged to a second maternal/fetal research network, would affect the enrollment in SUPPORT. We found that only 8% of women had been approached for another trial at the time of the SUPPORT consent discussion, probably because it was an antenatal consent and the window was early in gestation.

Because of the unique attributes of the NRN, we were able to obtain demographic data from the GDB for infants who were delivered in the SUPPORT window but were not enrolled in the study. Thus, we were able to compare infants who were vs. were not enrolled and those whose mothers were vs. were not approached. These groups differed in a number of significant areas. Most importantly, infants born to women who were not approached for consent were almost 6 times more likely not to have been exposed to antenatal steroids, an intervention known to be associated with better short and longer term outcomes for preterm infants. [2] They were also more likely to be more immature and their mothers were significantly less likely to have insurance and to have received prenatal care.

In a review of NIH funded interventional randomized controlled trials, Charlson and Horwitz found that only half such trials kept any data on subjects who were eligible but not enrolled, and for those trials which did keep data only 27% of eligible non-enrolled subjects were a result of subject refusal.[3] The Consolidated Standards for Reporting of Trials (CONSORT) is a document created with the intent of standardizing items reported in trial publications, including a checklist for necessary items and a flow chart of participants.[4,5] The standards require the quantifying of eligible populations but make no such requirement for identifying the demographics of this group or its similarity to the enrolled or consented populations. Our study demonstrates that requirement for antenatal consent results in the recruitment of infants that may not be representative of the population being studied. Following the CONSORT standards in all antenatal consent trials, both consented and waived, and obtaining basic demographic information for all eligible infants will help us understand whether similar reduction in enrollment occurs when the burden of consent is added to these trials and whether the enrolled infants are representative of the true eligible population.

Blinding and randomization have always been the benchmarks for protecting trials from bias. Investigators have shown that trials in which allocation to a study group is well concealed more accurately reflect the true study effect than those not well concealed.[6] However, these controls only

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

protect the trial from internal bias. Manning and Silverman have voiced concerns about selection bias, stating that a disproportionate number of vulnerable and deprived families are involved in clinical research.[7,8] Harth and Thong questioned parents who had volunteered in an asthma trial in Australia and concluded that volunteering parents were "significantly more socially disadvantaged and emotionally vulnerable." [9] In a study of recruitment and retention of premature infants into an early intervention program, Constantine et al found significant enrollment bias in this direction related to race, weight and site. [10] Zupancic et al. analyzed three postnatal trials in Canada, which has universal healthcare and other social benefits, and found no significant socio-economic difference between those who consented when compared with those who did not.[11] Mitchell and Kline, on the other hand, showed a significantly greater proportion of African-Americans, uninsured patients, and Medicaid recipients in the non-participant group in a minimal risk emergency department study.[12] Aagaard-Tillery and the NICHD Maternal Fetal Medicine (MFM) network found that blacks and Hispanics were significantly less likely to allow use of their genetic samples for future studies.[13]

Glassberg, Luce and Matthay analyzed the screening and enrollment of a trial of acute lung injury in two San Francisco hospitals, one an academic referral center and the other the public hospital for the city. [14] The percentage of screened infants enrolled was nearly 3 times higher in the academic center, a statistically significant difference ($p<.0001$). All of the centers in our trial were academic centers, but many included a relationship with a non-academic center. With the exception of the Zupancic trial, which took place in a country with universal healthcare, all of these reports of selection bias point toward the need to find a better method of enrolling truly representative populations for trials evaluating better practices.

The bias in our analysis would suggest that under privileged subjects were less likely to participate. Because this trial enrolled subjects from all socio-economic groups at 18 academic centers with long-term randomized trial experience, it is not likely that the bias involved represents an intention to include or not include any group. The logical conclusion is that the many subjects who ended up

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

excluded from this trial, despite the significant time and effort spent by the coordinators to include them, represent a failure of, or an innate problem with, the antenatal-consent process itself. Our observations, along with previous experience in a trial of a delivery room intervention[15], suggest that it is appropriate from an ethical perspective to allow trials that compare standard of care interventions to waive the consent process until after birth. This would ensure that the infants enrolled in such a trial do not differ significantly from the overall eligible population and insure the generalizability of the results.

Conclusion

Our prospective analysis of the process of antenatal consent enrollment in the NICHD Neonatal Research Network SUPPORT trial has shown that antenatal screening and consent are labor intensive, that actual patient enrollment numbers may be significantly lower than screening and consent rates, and that the population studied may not be representative of the total eligible population. In this complex interventional trial of preterm infants, nearly 5 women were identified as likely to deliver a baby in the window for every infant enrolled in the trial. Antenatal steroid use was significantly higher among infants enrolled in the SUPPORT study compared to those who were eligible but not enrolled, with a similar difference between infants born to approached and non-approached women. Along with quantifying the time and expense of antenatal consent, these observations point out the difficulties in attempting to recruit a representative population for prospective trials requiring antenatal consent and suggest that greater use of waiver of consent for trials that are low risk may be appropriate for future studies.

ABSTRACT

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

Objective:

This study was designed to quantify the time and effort involved in enrolling infants into the NICHD Neonatal Research Network (NRN) SUPPORT trial and to better predict the time required for recruitment into a complex interventional trial requiring antenatal consent.

Design/Methods:

A data form was designed to obtain information about eligible mothers who were available and approached at each center, to determine who approached them, how often they were approached, the duration of each contact, whether consent was obtained and if the infant(s) was enrolled. Infants born at Network centers who delivered in the SUPPORT window were entered into the NRN Generic Database. These data were used to identify infants who were eligible but not approached or enrolled.

Results

2828 women were identified at 18 collaborating units as being at risk for premature delivery at 24 to 27 6/7 wks GA between October 2005 and February 2009. 2228 were approached for informed consent. The most common reasons for not approaching mothers included fetal abnormalities, active labor and language barriers. A study coordinator/research nurse made 75% of all approaches. For 77% of those approached, consent was attempted < 3 times. (Overall mean 2.0 +/- 1.2). Estimated GA at time of screening was not different for those who consented versus those who did not. Seven percent of those approached were identified as having been approached for another maternal study and 1% for another neonatal study. Of the 2228 mothers approached, 1217 gave consent. Five hundred seventy-eight of those consented delivered 655 infants within the study window, and 535 of these delivered 610 infants that were enrolled. Forty-five consented infants born in the GA window were not enrolled. Only 19% of screened women delivered infants subsequently enrolled in the study. There was a significant relationship between performing a neonatal consult and obtaining consent ($p<.0001$). Centers that were also NICHD Maternal Fetal Medicine network centers enrolled at a higher rate and were more likely to use < 30 minutes to obtain consent. A significantly higher proportion of infants who delivered in the

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

study window but were not enrolled in SUPPORT had no exposure to antenatal steroids compared with infants who were enrolled. (15.7 vs. 3.8% p<.0001). The difference in lack of antenatal steroid exposure was even greater for the infants of approached vs. non-approached women (3.4 vs. 20.3%, p<.0001).

Conclusions:

In a complex interventional trial of preterm infants requiring antenatal consent, more than 5 women were identified as likely to deliver a baby in the window for each one who delivered an infant enrolled in the trial. Extrapolating these data to the entire SUPPORT trial suggests that over 2400 hours were spent screening greater than 6000 women to enroll 1317 infants in the trial. The differences between enrolled versus non-enrolled infants highlight the difficulties in attempting to recruit a representative population for prospective trials requiring antenatal consent.

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

Introduction:

The process of informed consent was established to ensure that subjects enrolled in research trials were appropriately informed as to the risks and benefits of the trial, came to the trial voluntarily, and represented an accurate cross-section of all subjects who would potentially receive benefit from or undergo the risks of the studied intervention. Traditionally, this consent is obtained directly from the subject when they are in condition to understand and participate in the process. In conducting trials on infants who will receive an intervention at or near the time of birth, the process requires approaching families prior to delivery to provide consent for their infant(s).

Funding for clinical trials sponsored by federal agencies and industry is often based on a model of capitation where a site is paid based on the number of subjects enrolled and some pre-calculated screening time. However, because prospective data comparing the number of families who are approached in the antenatal period to the number of infants who are actually enrolled have not previously been available, the current model may not adequately account for time spent by study staff to screen, approach and enroll all eligible subjects.

Early enrollment in the Surfactant Positive Airway Pressure and Pulse Oximetry Trial in Extremely Low Birth Weight Infants (SUPPORT) demonstrated that antenatal screening and consent were labor intensive and that actual patient enrollment numbers differed significantly from the screening and consent rates. Thus, this secondary study was designed to evaluate the antenatal screening and consent process to determine the factors that contribute to successful enrollment of patients in a complex trial conducted by an experienced multi-center trials network.

Methods:

This is a prospective cohort study of the antenatal consenting practices of research personnel in the multi-center Neonatal Research Network (NRN) funded by the Eunice Kennedy Shriver National Institute of Child Health and Human Development (NICHD). Data for this study were collected during the

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

last half of the NRN SUPPORT trial. The SUPPORT trial was designed to compare the use of early CPAP initiated in the delivery room to early intubation and surfactant given within the first hour of life, and to compare randomization to 2 different target SpO2 ranges during receipt of supplemental oxygen up to 36 weeks post menstrual age (PMA). Eligible infants were 24 0/7ths to 27 6/7ths weeks gestational age (GA) without known malformation for whom full postnatal treatment was expected.

Eligible subjects for the antenatal consent secondary study were those women who the Obstetrical/Perinatal staff felt were likely to deliver in the SUPPORT gestational age window. Clinical data were collected by trained research coordinators, and all analyses were performed at a central data coordinating center (DCC) (RTI International, Research Triangle Park, NC). Research staff self-reported study data using a one page data collection form. If the parent(s) were not approached for consent, the reason they were not approached was recorded. If they were approached, the staff recorded the total number of times the parent(s) were approached, the number of such attempts which were made by the research coordinator/RN, and whether OB permission was obtained to approach for antenatal consent. As a neonatal consult is often performed on this population, staff recorded whether a consult was performed, whether the consent was discussed during the consultation, and whether consent was obtained at the time of the consult. In some centers the Institutional Review Board required a consult be completed prior to consent, so this was also recorded. Women who were approached for SUPPORT were asked if they were approached for participation in any other studies either for themselves or their infants. Finally, the study staff was asked to estimate the time required to obtain a decision regarding consent.

Data were collected at each of the 18 NICHD NRN centers until fifty mothers had delivered within the window at the center. Data forms were keyed by the centers and transmitted electronically to the DCC. Infants born at Network centers who delivered in the SUPPORT window were entered into the NRN Generic Database (GDB) which, before 2008, collected delivery and demographic data on infants between 401 and 1500g inclusive birth weight who were inborn at NRN centers or admitted to

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

the NICU within 14 days of age. Beginning in 2008, the database collected infants who were 1) inborn and between 401 grams and 1000 grams inclusive birth weight and/or 2) inborn and between 22 0/7 and 28 6/7 weeks (<29 weeks) inclusive gestational age. GDB data were used to evaluate whether infants enrolled in the SUPPORT trial represented the entire eligible Network population.

To determine the representativeness of the population enrolled in the SUPPORT trial, data from the GDB were obtained for those infants born at NRN centers during the period of SUPPORT trial enrollment who qualified to participate in SUPPORT. This information included whether prenatal care was obtained, the use of antenatal steroids and demographic data. These data were compared for infants who were or were not enrolled in SUPPORT to assess whether the trial had enrolled a representative sample of the available population. In addition, comparisons were made between eligible infants whose mothers were or were not approached for SUPPORT.

We performed bivariate statistical analyses using Chi-Square and Student's t-tests. All statistical analyses were performed using SAS version 9.1.3 (SAS Institute Inc., Cary, NC). A p value of less than 0.05 was considered statistically significant. This trial was approved by the Institutional Review Boards of all participating centers as well as that of RTI.

Results

Between October 2005 and February 2009, a total of 2828 women were identified at 18 NRN centers as being at risk for delivering a premature infant between 24 to 27 6/7 wks GA and otherwise eligible for participation in the SUPPORT trial. Two additional NRN centers did not participate in the antenatal consent trial and 4 who did participate did not identify 50 eligible women between the start of data collection for the antenatal consent study and the end of the SUPPORT trial. Four centers identified more than 50 women (mean 82) before they were informed that they could stop collecting data. All data collected by participating centers have been included in this analysis. Results of an analysis using only the first 50 women from the centers that over-enrolled were not significantly different. Data for screening, enrollment and consent by center are presented in Figure 1.

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

2228 women were approached for informed consent. The two most frequent reasons for not attempting to obtain a consent were early discharge and a lack of time prior to delivery (Table 2). Common choices within the "other" category in the table were early discharge, the ability of the mother to give consent, fetal abnormalities, and language barriers that made informed consent impossible. Reasons mothers were considered unable to give consent included being in active labor, being too young, and having either a mental or physical health issue which precluded them being approached. A study coordinator or research RN made 75% of all approaches. For 77% of those women approached, consent was attempted < 3 times. (Overall mean 2.0 +/- 1.2). The frequency of approaches ranged from 1 (n=900) to 11 (n=2) times. The median time spent to obtain a decision regarding consent was less than 1 hour regardless of the decision. The estimated GA at time of screening was not significantly different for those who consented versus those who did not. Of the 2228 mothers approached, 1217 gave consent, 578 subsequently delivered 655 infants within the SUPPORT study window, and 535 delivered 610 infants who were enrolled (Figure 2). Forty-five consented infants born in the GA window (7%) were not enrolled, usually due to lack of staffing, equipment, or time. Only 19% of those mothers screened delivered infants who were subsequently enrolled in the study. A neonatal consult was performed in 70% of cases. There was a significant relationship between performing a neonatal consult and obtaining consent ($p < .0001$), but consent was only obtained during the consult 12% of the time. Centers that were also NICHD Maternal Fetal Medicine network centers enrolled at a higher rate and were more likely to require less than 30 minutes to obtain a consent decision. The median time spent to obtain a decision regarding consent for all centers was less than 1 hour regardless of the decision.

Infants of non-approached and approached mothers were different in several important ways as shown in Table 1. Infants of approached mothers were more likely to be non-Hispanic white ($p<0.0001$); the mothers were more likely to be older ($p=0.0210$) and to have a high school education ($p<0.0001$), medical insurance ($p<0.0001$), and at least one PNC visit ($p<0.0001$). A significantly higher proportion of infants born in the study window whose mothers were not approached for SUPPORT had no exposure to

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

antenatal steroids compared with infants whose mothers were approached (20.3% vs 3.4%, p<.0001). Maternal gravidity and parity were not significantly different between these groups.

Infants who were enrolled in SUPPORT and those who were not enrolled were also significantly different. Non-enrolled infants had mothers who were significantly less likely to have insurance (p=0.0011) and to have received prenatal care (p=0.0039), and were over 4 times more likely to have gone without antenatal steroids (15.7% vs. 3.8%, p<0.0001) (Table 2).

Discussion:

To our knowledge this is the first neonatal study to evaluate the time and work required to approach and obtain consent from parents for the enrollment of their premature infants who at the time of the consent were not yet born. Our results reveal that 5 families needed to be identified and screened for every one that had an infant successfully enrolled. Only 47% of women from whom consent was obtained went on to deliver infants in the study window. Though the time needed to obtain consent was collected as a discrete variable, we found that the median was between 30 minutes and 1 hour. Multiplying these bounds by the number of women approached for each enrolled infant (3.7) yields a value for coordinator time required to obtain an enrolled infant at between 1.8 and 3.7 hours. This includes time spent approaching women who did not consent and consenting women who did not deliver in the window. It does not account for time spent screening women who were not approached for consent.

Morley et al reviewed parental willingness to participate in multiple trials in the neonatal period and found that most (74%) were willing to allow their baby to participate in multiple trials. [1] We had concerns that the burden of being approached for multiple trials, especially since 5 centers belonged to a second maternal/fetal research network, would affect the enrollment in SUPPORT. We found that only 8% of women had been approached for another trial at the time of the SUPPORT consent discussion, probably because it was an antenatal consent and the window was early in gestation.

Because of the unique attributes of the NRN, we were able to obtain demographic data from the GDB for infants who were delivered in the SUPPORT window but were not enrolled in the study. Thus, we were able to compare infants who were vs. were not enrolled and those whose mothers were vs. were not approached. These groups differed in a number of significant areas. Most importantly, infants born to women who were not approached for consent were almost 6 times more likely not to have been exposed to antenatal steroids, an intervention known to be associated with better short and longer term outcomes for preterm infants. [2] They were also more likely to be more immature and their mothers were significantly less likely to have insurance and to have received prenatal care.

In a review of NIH funded interventional randomized controlled trials, Charlson and Horwitz found that only half such trials kept any data on subjects who were eligible but not enrolled, and for those trials which did keep data only 27% of eligible non-enrolled subjects were a result of subject refusal.[3] The Consolidated Standards for Reporting of Trials (CONSORT) is a document created with the intent of standardizing items reported in trial publications, including a checklist for necessary items and a flow chart of participants.[4,5] The standards require the quantifying of eligible populations but make no such requirement for identifying the demographics of this group or its similarity to the enrolled or consented populations. Our study demonstrates that requirement for antenatal consent results in the recruitment of infants that may not be representative of the population being studied. Following the CONSORT standards in all antenatal consent trials, both consented and waived, and obtaining basic demographic information for all eligible infants will help us understand whether similar reduction in enrollment occurs when the burden of consent is added to these trials and whether the enrolled infants are representative of the true eligible population.

Blinding and randomization have always been the benchmarks for protecting trials from bias. Investigators have shown that trials in which allocation to a study group is well concealed more accurately reflect the true study effect than those not well concealed.[6] However, these controls only

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

protect the trial from internal bias. Manning and Silverman have voiced concerns about selection bias, stating that a disproportionate number of vulnerable and deprived families are involved in clinical research.[7,8] Harth and Thong questioned parents who had volunteered in an asthma trial in Australia and concluded that volunteering parents were "significantly more socially disadvantaged and emotionally vulnerable." [9] In a study of recruitment and retention of premature infants into an early intervention program, Constantine et al found significant enrollment bias in this direction related to race, weight and site. [10] Zupancic et al. analyzed three postnatal trials in Canada, which has universal healthcare and other social benefits, and found no significant socio-economic difference between those who consented when compared with those who did not.[11] Mitchell and Kline, on the other hand, showed a significantly greater proportion of African-Americans, uninsured patients, and Medicaid recipients in the non-participant group in a minimal risk emergency department study.[12] Aagaard-Tillery and the NICHD Maternal Fetal Medicine (MFM) network found that blacks and Hispanics were significantly less likely to allow use of their genetic samples for future studies.[13]

Glassberg, Luce and Matthay analyzed the screening and enrollment of a trial of acute lung injury in two San Francisco hospitals, one an academic referral center and the other the public hospital for the city. [14] The percentage of screened infants enrolled was nearly 3 times higher in the academic center, a statistically significant difference ($p<.0001$). All of the centers in our trial were academic centers, but many included a relationship with a non-academic center. With the exception of the Zupancic trial, which took place in a country with universal healthcare, all of these reports of selection bias point toward the need to find a better method of enrolling truly representative populations for trials evaluating better practices.

The bias in our analysis would suggest that under privileged subjects were less likely to participate. Because this trial enrolled subjects from all socio-economic groups at 18 academic centers with long-term randomized trial experience, it is not likely that the bias involved represents an intention to include or not include any group. The logical conclusion is that the many subjects who ended up

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

excluded from this trial, despite the significant time and effort spent by the coordinators to include them, represent a failure of, or an innate problem with, the antenatal-consent process itself. Our observations, along with previous experience in a trial of a delivery room intervention[15], suggest that it is appropriate from an ethical perspective to allow trials that compare standard of care interventions to waive the consent process until after birth. This would ensure that the infants enrolled in such a trial do not differ significantly from the overall eligible population and insure the generalizability of the results.

Conclusion

Our prospective analysis of the process of antenatal consent enrollment in the NICHD Neonatal Research Network SUPPORT trial has shown that antenatal screening and consent are labor intensive, that actual patient enrollment numbers may be significantly lower than screening and consent rates, and that the population studied may not be representative of the total eligible population. In this complex interventional trial of preterm infants, nearly 5 women were identified as likely to deliver a baby in the window for every infant enrolled in the trial. Antenatal steroid use was significantly higher among infants enrolled in the SUPPORT study compared to those who were eligible but not enrolled, with a similar difference between infants born to approached and non-approached women. Along with quantifying the time and expense of antenatal consent, these observations point out the difficulties in attempting to recruit a representative population for prospective trials requiring antenatal consent and suggest that greater use of waiver of consent for trials that are low risk may be appropriate for future studies.

ABSTRACT

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

Objective:

This study was designed to quantify the time and effort involved in enrolling infants into the NICHD Neonatal Research Network (NRN) SUPPORT trial and to better predict the time required for recruitment into a complex interventional trial requiring antenatal consent.

Design/Methods:

A data form was designed to obtain information about eligible mothers who were available and approached at each center, to determine who approached them, how often they were approached, the duration of each contact, whether consent was obtained and if the infant(s) was enrolled. Infants born at Network centers who delivered in the SUPPORT window were entered into the NRN Generic Database. These data were used to identify infants who were eligible but not approached or enrolled.

Results

2828 women were identified at 18 collaborating units as being at risk for premature delivery at 24 to 27 6/7 wks GA between October 2005 and February 2009. 2228 were approached for informed consent. The most common reasons for not approaching mothers included fetal abnormalities, active labor and language barriers. A study coordinator/research nurse made 75% of all approaches. For 77% of those approached, consent was attempted < 3 times. (Overall mean 2.0 +/- 1.2). Estimated GA at time of screening was not different for those who consented versus those who did not. Seven percent of those approached were identified as having been approached for another maternal study and 1% for another neonatal study. Of the 2228 mothers approached, 1217 gave consent. Five hundred seventy-eight of those consented delivered 655 infants within the study window, and 535 of these delivered 610 infants that were enrolled. Forty-five consented infants born in the GA window were not enrolled. Only 19% of screened women delivered infants subsequently enrolled in the study. There was a significant relationship between performing a neonatal consult and obtaining consent ($p<.0001$). Centers that were also NICHD Maternal Fetal Medicine network centers enrolled at a higher rate and were more likely to use < 30 minutes to obtain consent. A significantly higher proportion of infants who delivered in the

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

study window but were not enrolled in SUPPORT had no exposure to antenatal steroids compared with infants who were enrolled. (15.7 vs. 3.8% p<.0001). The difference in lack of antenatal steroid exposure was even greater for the infants of approached vs. non-approached women (3.4 vs. 20.3%, p<.0001).

Conclusions:

In a complex interventional trial of preterm infants requiring antenatal consent, more than 5 women were identified as likely to deliver a baby in the window for each one who delivered an infant enrolled in the trial. Extrapolating these data to the entire SUPPORT trial suggests that over 2400 hours were spent screening greater than 6000 women to enroll 1317 infants in the trial. The differences between enrolled versus non-enrolled infants highlight the difficulties in attempting to recruit a representative population for prospective trials requiring antenatal consent.

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

Introduction:

The process of informed consent was established to ensure that subjects enrolled in research trials were appropriately informed as to the risks and benefits of the trial, came to the trial voluntarily, and represented an accurate cross-section of all subjects who would potentially receive benefit from or undergo the risks of the studied intervention. Traditionally, this consent is obtained directly from the subject when they are in condition to understand and participate in the process. In conducting trials on infants who will receive an intervention at or near the time of birth, the process requires approaching families prior to delivery to provide consent for their infant(s).

Funding for clinical trials sponsored by federal agencies and industry is often based on a model of capitation where a site is paid based on the number of subjects enrolled and some pre-calculated screening time. However, because prospective data comparing the number of families who are approached in the antenatal period to the number of infants who are actually enrolled have not previously been available, the current model may not adequately account for time spent by study staff to screen, approach and enroll all eligible subjects.

Early enrollment in the Surfactant Positive Airway Pressure and Pulse Oximetry Trial in Extremely Low Birth Weight Infants (SUPPORT) demonstrated that antenatal screening and consent were labor intensive and that actual patient enrollment numbers differed significantly from the screening and consent rates. Thus, this secondary study was designed to evaluate the antenatal screening and consent process to determine the factors that contribute to successful enrollment of patients in a complex trial conducted by an experienced multi-center trials network.

Methods:

This is a prospective cohort study of the antenatal consenting practices of research personnel in the multi-center Neonatal Research Network (NRN) funded by the Eunice Kennedy Shriver National Institute of Child Health and Human Development (NICHD). Data for this study were collected during the

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

last half of the NRN SUPPORT trial. The SUPPORT trial was designed to compare the use of early CPAP initiated in the delivery room to early intubation and surfactant given within the first hour of life, and to compare randomization to 2 different target SpO2 ranges during receipt of supplemental oxygen up to 36 weeks post menstrual age (PMA). Eligible infants were 24 0/7ths to 27 6/7ths weeks gestational age (GA) without known malformation for whom full postnatal treatment was expected.

Eligible subjects for the antenatal consent secondary study were those women who the Obstetrical/Perinatal staff felt were likely to deliver in the SUPPORT gestational age window. Clinical data were collected by trained research coordinators, and all analyses were performed at a central data coordinating center (DCC) (RTI International, Research Triangle Park, NC). Research staff self-reported study data using a one page data collection form. If the parent(s) were not approached for consent, the reason they were not approached was recorded. If they were approached, the staff recorded the total number of times the parent(s) were approached, the number of such attempts which were made by the research coordinator/RN, and whether OB permission was obtained to approach for antenatal consent. As a neonatal consult is often performed on this population, staff recorded whether a consult was performed, whether the consent was discussed during the consultation, and whether consent was obtained at the time of the consult. In some centers the Institutional Review Board required a consult be completed prior to consent, so this was also recorded. Women who were approached for SUPPORT were asked if they were approached for participation in any other studies either for themselves or their infants. Finally, the study staff was asked to estimate the time required to obtain a decision regarding consent.

Data were collected at each of the 18 NICHD NRN centers until fifty mothers had delivered within the window at the center. Data forms were keyed by the centers and transmitted electronically to the DCC. Infants born at Network centers who delivered in the SUPPORT window were entered into the NRN Generic Database (GDB) which, before 2008, collected delivery and demographic data on infants between 401 and 1500g inclusive birth weight who were inborn at NRN centers or admitted to

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

the NICU within 14 days of age. Beginning in 2008, the database collected infants who were 1) inborn and between 401 grams and 1000 grams inclusive birth weight and/or 2) inborn and between 22 0/7 and 28 6/7 weeks (<29 weeks) inclusive gestational age. GDB data were used to evaluate whether infants enrolled in the SUPPORT trial represented the entire eligible Network population.

To determine the representativeness of the population enrolled in the SUPPORT trial, data from the GDB were obtained for those infants born at NRN centers during the period of SUPPORT trial enrollment who qualified to participate in SUPPORT. This information included whether prenatal care was obtained, the use of antenatal steroids and demographic data. These data were compared for infants who were or were not enrolled in SUPPORT to assess whether the trial had enrolled a representative sample of the available population. In addition, comparisons were made between eligible infants whose mothers were or were not approached for SUPPORT.

We performed bivariate statistical analyses using Chi-Square and Student's t-tests. All statistical analyses were performed using SAS version 9.1.3 (SAS Institute Inc., Cary, NC). A p value of less than 0.05 was considered statistically significant. This trial was approved by the Institutional Review Boards of all participating centers as well as that of RTI.

Results

Between October 2005 and February 2009, a total of 2828 women were identified at 18 NRN centers as being at risk for delivering a premature infant between 24 to 27 6/7 wks GA and otherwise eligible for participation in the SUPPORT trial. Two additional NRN centers did not participate in the antenatal consent trial and 4 who did participate did not identify 50 eligible women between the start of data collection for the antenatal consent study and the end of the SUPPORT trial. Four centers identified more than 50 women (mean 82) before they were informed that they could stop collecting data. All data collected by participating centers have been included in this analysis. Results of an analysis using only the first 50 women from the centers that over-enrolled were not significantly different. Data for screening, enrollment and consent by center are presented in Figure 1.

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

2228 women were approached for informed consent. The two most frequent reasons for not attempting to obtain a consent were early discharge and a lack of time prior to delivery (Table 2). Common choices within the "other" category in the table were early discharge, the ability of the mother to give consent, fetal abnormalities, and language barriers that made informed consent impossible. Reasons mothers were considered unable to give consent included being in active labor, being too young, and having either a mental or physical health issue which precluded them being approached. A study coordinator or research RN made 75% of all approaches. For 77% of those women approached, consent was attempted < 3 times. (Overall mean 2.0 +/- 1.2). The frequency of approaches ranged from 1 (n=900) to 11 (n=2) times. The median time spent to obtain a decision regarding consent was less than 1 hour regardless of the decision. The estimated GA at time of screening was not significantly different for those who consented versus those who did not. Of the 2228 mothers approached, 1217 gave consent, 578 subsequently delivered 655 infants within the SUPPORT study window, and 535 delivered 610 infants who were enrolled (Figure 2). Forty-five consented infants born in the GA window (7%) were not enrolled, usually due to lack of staffing, equipment, or time. Only 19% of those mothers screened delivered infants who were subsequently enrolled in the study. A neonatal consult was performed in 70% of cases. There was a significant relationship between performing a neonatal consult and obtaining consent ($p < .0001$), but consent was only obtained during the consult 12% of the time. Centers that were also NICHD Maternal Fetal Medicine network centers enrolled at a higher rate and were more likely to require less than 30 minutes to obtain a consent decision. The median time spent to obtain a decision regarding consent for all centers was less than 1 hour regardless of the decision.

Infants of non-approached and approached mothers were different in several important ways as shown in Table 1. Infants of approached mothers were more likely to be non-Hispanic white ($p<0.0001$); the mothers were more likely to be older ($p=0.0210$) and to have a high school education ($p<0.0001$), medical insurance ($p<0.0001$), and at least one PNC visit ($p<0.0001$). A significantly higher proportion of infants born in the study window whose mothers were not approached for SUPPORT had no exposure to

antenatal steroids compared with infants whose mothers were approached (20.3% vs 3.4%, p<.0001). Maternal gravidity and parity were not significantly different between these groups.

Infants who were enrolled in SUPPORT and those who were not enrolled were also significantly different. Non-enrolled infants had mothers who were significantly less likely to have insurance (p=0.0011) and to have received prenatal care (p=0.0039), and were over 4 times more likely to have gone without antenatal steroids (15.7% vs. 3.8%, p<0.0001) (Table 2).

Discussion:

To our knowledge this is the first neonatal study to evaluate the time and work required to approach and obtain consent from parents for the enrollment of their premature infants who at the time of the consent were not yet born. Our results reveal that 5 families needed to be identified and screened for every one that had an infant successfully enrolled. Only 47% of women from whom consent was obtained went on to deliver infants in the study window. Though the time needed to obtain consent was collected as a discrete variable, we found that the median was between 30 minutes and 1 hour. Multiplying these bounds by the number of women approached for each enrolled infant (3.7) yields a value for coordinator time required to obtain an enrolled infant at between 1.8 and 3.7 hours. This includes time spent approaching women who did not consent and consenting women who did not deliver in the window. It does not account for time spent screening women who were not approached for consent.

Morley et al reviewed parental willingness to participate in multiple trials in the neonatal period and found that most (74%) were willing to allow their baby to participate in multiple trials. [1] We had concerns that the burden of being approached for multiple trials, especially since 5 centers belonged to a second maternal/fetal research network, would affect the enrollment in SUPPORT. We found that only 8% of women had been approached for another trial at the time of the SUPPORT consent discussion, probably because it was an antenatal consent and the window was early in gestation.

Because of the unique attributes of the NRN, we were able to obtain demographic data from the GDB for infants who were delivered in the SUPPORT window but were not enrolled in the study. Thus, we were able to compare infants who were vs. were not enrolled and those whose mothers were vs. were not approached. These groups differed in a number of significant areas. Most importantly, infants born to women who were not approached for consent were almost 6 times more likely not to have been exposed to antenatal steroids, an intervention known to be associated with better short and longer term outcomes for preterm infants. [2] They were also more likely to be more immature and their mothers were significantly less likely to have insurance and to have received prenatal care.

In a review of NIH funded interventional randomized controlled trials, Charlson and Horwitz found that only half such trials kept any data on subjects who were eligible but not enrolled, and for those trials which did keep data only 27% of eligible non-enrolled subjects were a result of subject refusal.[3] The Consolidated Standards for Reporting of Trials (CONSORT) is a document created with the intent of standardizing items reported in trial publications, including a checklist for necessary items and a flow chart of participants.[4,5] The standards require the quantifying of eligible populations but make no such requirement for identifying the demographics of this group or its similarity to the enrolled or consented populations. Research from the California Department of Health Services reviewed the effect of the introduction of tandem Mass Spectrometry (MS/MS) to the California Newborn Screening program.[6] This involved another test on an already collected blood spot, for which it was decided informed consent was necessary. They found that the burden of adding informed consent to the screening process resulted in only 50% of infants being screened for the new test. Twenty one percent of participating hospitals did not offer the screening because of the burden of providing informed consent. It is very possible that failure rates for enrollment of infants in trials that require consent in the antenatal period is much higher than is currently believed. Following the CONSORT standards in all antenatal consent trials, both consented and waived, and obtaining basic demographic information for

all eligible infants will help us understand whether similar reduction in enrollment occurs when the burden of consent is added to these trials and whether the enrolled infants are representative of the true eligible population.

Blinding and randomization have always been the benchmarks for protecting trials from bias. Investigators have shown that trials in which allocation to a study group is well concealed more accurately reflect the true study effect than those not well concealed.[7] However, these controls only protect the trial from internal bias. Manning and Silverman have voiced concerns about selection bias, stating that a disproportionate number of vulnerable and deprived families are involved in clinical research.[8,9] Harth and Thong questioned parents who had volunteered in an asthma trial in Australia and concluded that volunteering parents were "significantly more socially disadvantaged and emotionally vulnerable." [10] In a study of recruitment and retention of premature infants into an early intervention program, Constantine et al found significant enrollment bias in this direction related to race, weight and site. [11] Zupancic et al. analyzed three postnatal trials in Canada, which has universal healthcare and other social benefits, and found no significant socio-economic difference between those who consented when compared with those who did not.[12] Mitchell and Kline, on the other hand, showed a significantly greater proportion of African-Americans, uninsured patients, and Medicaid recipients in the non-participant group in a minimal risk emergency department study.[13] Aagaard-Tillery and the NICHD Maternal Fetal Medicine (MFM) network found that blacks and Hispanics were significantly less likely to allow use of their genetic samples for future studies.[14]

Glassberg, Luce and Matthay analyzed the screening and enrollment of a trial of acute lung injury in two San Francisco hospitals, one an academic referral center and the other the public hospital for the city. [15] The percentage of screened infants enrolled was nearly 3 times higher in the academic center, a statistically significant difference ($p<.0001$). All of the centers in our trial were academic centers, but many included a relationship with a non-academic center. With the exception of Zupancic, which took place in a country with universal healthcare, all of these reports of selection bias point

toward the need to find a better method of enrolling truly representative populations for trials evaluating better practices.

The bias in our analysis would suggest that under privileged subjects were less likely to participate. Because this trial enrolled subjects from all socio-economic groups at 18 academic centers with long-term randomized trial experience, it is not likely that the bias involved represents an intention to include or not include any group. The logical conclusion is that the many subjects who ended up excluded from this trial, despite the significant time and effort spent by the coordinators to include them, represent a failure of, or an innate problem with, the antenatal-consent process itself. Our observations, along with previous experience in a trial of a delivery room intervention[16], suggest that it is appropriate from an ethical perspective to allow trials that compare standard of care interventions to waive the consent process until after birth. This would ensure that the infants enrolled in such a trial do not differ significantly from the overall eligible population and insure the generalizability of the results.

Conclusion

Our prospective analysis of the process of antenatal consent enrollment in the NICHD Neonatal Research Network SUPPORT trial has shown that antenatal screening and consent are labor intensive, that actual patient enrollment numbers may be significantly lower than screening and consent rates, and that the population studied may not be representative of the total eligible population. In this complex interventional trial of preterm infants, nearly 5 women were identified as likely to deliver a baby in the window for every infant enrolled in the trial. Antenatal steroid use was significantly higher among infants enrolled in the SUPPORT study compared to those who were eligible but not enrolled, with a similar difference between infants born to approached and non-approached women. Along with quantifying the time and expense of antenatal consent, these observations point out the difficulties in attempting to recruit a representative population for prospective trials requiring antenatal consent and suggest that greater use of waiver of consent for trials that are low risk may be appropriate for future studies.

Hi,
We are missing a few SUPPORT outcomes. Recruitment is finished in the trial and we are trying to get all of the needed information into the DMS in a timely manner. Please let us know how you are doing.

Thanks for all the hard work!!
Rose

To: Gantz, Marie
Cc: Betty_Vohr@brown.edu; Higgins, Rosemary (NIH/NICHD) [E]; Finer, Neil; Das, Abhik
Subject: RE: Support FUP

Marie,

How are we using the language scores? How is the Bayley III composite score (cognitive + language) derived? Could we use the combined cognitive + language scores for the NDI? The cognitive composite is a much more normal distribution. The Bayley III language scores are skewed downward.

MG: Right now, the Bayley III language score is not incorporated into our network definition of NDI. Your questions about combining the cognitive and language scores would be better answered by Betty, as I am not familiar with how the scores are derived, and I believe that any change to the NDI definition would have to be discussed by the follow up subcommittee.

What is the difference in sample size needed if NDI is the primary outcome using cognitive scores < 70 from the Bayley IIII instead of the Bayley II?
What is the effect on sample size needed if we used the Bayley II MDI or Bayley III cognitive score <70 alone as opposed to using it as a component of NDI?
What sample size is needed if we compare cognitive scores < 85 (< 1 SD below the mean), alone and as a component of NDI?

MG: The sample size for the SUPPORT trial were based on a conservative event rate of 50% (because when there are multiple outcomes the one with prevalence nearest 50% drives the sample size requirement) and the sample size was then increased to account for the randomization of multiples to the same group and for loss to follow up. So, the sample size calculations were not influenced by the distribution of the Bayley II scores and would not be impacted by a switch to the Bayley III.

For Support, were the sample size adjustments of 12% for multiples (randomized together) and 17% for LTFU used to arrive at a final sample size of 1310? How is the multiples adjustment derived? How would the sample size adjustment be changed if multiples were randomized separately?

MG: The sample size adjustments for multiples and loss to FU were used to arrive at the final sample size of 1310. The multiples adjustment was based on the multiples rate in the GDB. Without both adjustments, the sample size would have been about 1000.

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

Although the NDI results using the Bayley III cognitive or composite scores will not be comparable to previous studies that used the Bayley II MDI, won't the relative differences between control and intervention arms within an individual RCT using the Bayley III be similar?

MG: The differences would be similar unless the intervention had a different impact on the Bayley III outcome than it had on the Bayley II outcome.

How does using a cutoff of below 85 rather than below 70 affect comparison of the Bayley II vs III? According to the NRN% Distribution for Bayley II MDI and Bayley III Cognitive score (12/17/08) accompanying the Technical Report, there are substantially more children on the Bayley II below the 85 cutoff. How much closer are the curves if the Bayley III language scores are added to the cognitive scores?

MG: See attached for frequencies of Bayley II and III scores where you can see the percent of children with scores below 70 and below 85. These data are for GDB infants born in 2004-2007 who have either the Bayley II or III.

Please send the distribution statistics for the Bayley II MDI and PDI in the same format as the distribution scores you sent Wade Rich for the Bayley III (Mean, SD, Median, Modes, Skewness, quartiles, etc.....).

MG: See attached for distributions of the Bayley II and III scores.

Thanks for your helping me understand this.

Yvonne

Cc: Gantz, Marie; Finer, Neil
Subject: RE: Support FUP

The sample size calculations in the SUPPORT protocol also mention the follow up outcome of death or NDI, though the primary outcomes are death or BPD and death or ROP. (Page 24 of the protocol states: "Thus the actual sample size for this trial would be 1310 for 80% power for detecting an absolute difference of 10% in the two primary outcomes and the NDI secondary outcome.") Of course, these were based on the Bayley II and may not obtain for the Bayley III. I am happy to discuss this issue as well.

Thanks

Subject: RE: Support FUP

Yvonne
Marie Gantz is the statistician for SUPPORT. The sample size for SUPPORT was determined based on the primary outcomes of BPD/ROP/ and death. FU was originally listed as a secondary outcome.

Confidentially, children are scoring better on the Bayley III as opposed to the Bayley II. For an upcoming trial, we are using a cognitive score of < 85 on the Bayley III as one component of neurodevelopmental impairment.

Perhaps we should discuss this one the follow up call scheduled for mid-July?
let me know

Regards
Rose

Support sample will have the Bayley 3 including motor scales vs the abbreviated Bayley 3 if we began to use the complete Bayley by September 1, October 1, November 1 allowing ~3 months for the additional certification?

Let's talk about this at the next follow-up call. Should we move the call up to June since the sooner we make a decision, the sooner we will complete moptor scales certification and be able to begin using the data? If most centers are already doing the motor scales the certification should be fairly rapid.

Good idea. I have also brought up previously perfoming the entire Bayley III including fine and gross motor going forward. Test time has decreased. Most sites are already doing the motor component. We would need to certify testers on the motor scores and have Abik give us a start-up time. Both Terri Leach and Vicki Watson at our site support this addition.

Marie Gantz is the statistician for SUPPORT. The sample size for SUPPORT was determined based on the primary outcomes of BPD/ROP/ and death. FU was originally listed as a secondary outcome.

Confidentially, children are scoring better on the Bayley III as opposed to the Bayley II. For an upcoming trial, we are using a cognitive score of < 85 on the Bayley III as one component of neurodevelopmental impairment.

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

Perhaps we should discuss this one the follow up call scheduled for mid-July?

Comments regarding 6-7 year SUPPORT Neuroimaging and Neurodevelopmental Outcomes
Dallas 5/29/09

Have discussed this with our psychologist, and in general we think the proposed set of assessments and parent questionnaires constitute a very good battery of assessment tools.

That said, we think it will be important to further delineate how the results of these assessments will be used in evaluating and interpreting outcomes, especially with regards to tools which are intended for screening purposes, such as the SCQ. We need to be cautious about interpreting results of a screening tool with limited specificity and positive predictive value as diagnostic of ASD.

Moreover, the intended use of an ASD screening tool in analysis and interpretation of outcomes would also be one important factor to consider in choosing one tool over another. The SCQ does have fairly sensitivity in multiple studies assessing its validity, though design of these studies do vary and sample sizes tend to be relatively small. However, specificity is as low as 58% in some studies. Of course, both parameters depend on what cutoff is used; and a paper by Allen et al (J Autism Dev Disord 37:1272-1278 from 2007) suggests that a lower cut-off has a better AUC on ROC analysis than the standard one. Several authors make the point that this tool should not be used for diagnostic purposes.

According to the information provided by Myriam, the SRS may a lower sensitivity but higher specificity. Again, depending on the intended use of results, the additional information regarding different dimensions may or may not be of additional value, especially considering this is still a screening tool.

Finally, on a totally different note, our psychologist thinks the time estimates for some of the psych tests may be somewhat optimistic. As stated, the neuro + psych evals add up to about 2.5 hours and the questionnaires to about 1.5 hours. Depending on the child and the parent, these may need to be administered sequentially, rather than in parallel. That would add up to a 4 hour session, not including breaks, which is long, but not unusual for a thorough psychological evaluation. Our psychologist indicated it would be important to have good testing finesse in being able to offer min-breaks in-between various tests, and think that a 6-7 year old is likely to require more than 1 break.

Yvonne,
I dont see a disadvantage. It would not be used specifically for the outcome analysis of the Support sample, but certainly could be used for other studies or for the comparison of Bayley III to II. As it is several of the sites are already doing it but not entering the data.

Subject: RE: Support FUP

Betty,

Is there a disadvantage of doing the whole Bayley on the remaining Support sample? We don't have to use it in our final analysis, but it may give us more information about what to do with the Bayley III in future studies and how to compare the Bayley II and III, especially as we would have done the abbreviated and full Bayley within the same group. ¼ of the Support population would be 300+ children .

So if we started to do a full Bayley in 9/09 we would have the full Bayley on ~ ¼ of our sample?

Subject: RE: Support FUP

I agree with Betty that we should in clude the motor scales of the Bayley 3 from some point onwards for all study follow-up visits. Abhik, what proportion of the Support sample will have the Bayley 3 including motor scales vs the abbreviated Bayley 3 if we began to use the complete Bayley by September 1, October 1, November 1 allowing ~3 months for the additional certification?

Let's talk about this at the next follow-up call. Should we move the call up to June since the sooner we make a decision, the sooner we will complete moptor scales certification and be able to begin using the data? If most centers are already doing the motor scales the certification should be fairly rapid.

Subject: RE: Support FUP

Good idea. I have also brought up previously perfoming the entire Bayley III including fine and gross motor going forward. Test time has decreased. Most sites are already doing the motor component. We would need to certify testers on the motor scores and have Abik give us a start-up time. Both Terri Leach and Vicki Watson at our site support this addition.

originally listed as a secondary outcome.

Confidentially, children are scoring better on the Bayley III as opposed to the Bayley II. For an upcoming trial, we are using a cognitive score of < 85 on the Bayley III as one component of neurodevelopmental impairment.

Perhaps we should discuss this one the follow up call scheduled for mid-July? let me know

Regards
Rose

Betty and Rose,

As I have not been part of the primary group, who is the best person(s) to talk to at RTI and within our follow-up group about the sample size/Bayley 3 questions for the Support trial so I can best understand the issues?

Thanks.

Subject: Request for SUPPORT forms

Hi
Dr. Finer has requested permission to use the SUPPORT forms and manual for his R34 clinical trial planning grant for the PreSox trial sponsored by NICHD. Please send me a yes/no vote by June 2.

Thanks
Rose

I agree with Betty that we should in clude the motor scales of the Bayley 3 from some point onwards for all study follow-up visits. Abhik, what proportion of the Support sample will have the Bayley 3 including motor scales vs the abbreviated Bayley 3 if we began to use the complete Bayley by September 1, October 1, November 1 allowing ~3 months for the additional certification?

Let's talk about this at the next follow-up call. Should we move the call up to June since the sooner we make a decision, the sooner we will complete moptor scales certification and be able to begin using the data? If most centers are already doing the motor scales the certification should be fairly rapid.

Subject: RE: Support FUP

Good idea. I have also brought up previously perfoming the entire Bayley III including fine and gross motor going forward. Test time has decreased. Most sites are already doing the motor component. We would need to certify testers on the motor scores and have Abik give us a start-up time. Both Terri Leach and Vicki Watson at our site support this addition.

Subject: RE: Support FUP

Yvonne
Marie Gantz is the statistician for SUPPORT. The sample size for SUPPORT was determined based on the primary outcomes of BPD/ROP/ and death. FU was originally listed as a secondary outcome.

Confidentially, children are scoring better on the Bayley III as opposed to the Bayley II. For an upcoming trial, we are using a cognitive score of < 85 on the Bayley III as one component of neurodevelopmental impairment.

Perhaps we should discuss this one the follow up call scheduled for mid-July?
let me know

Betty and Rose,

As I have not been part of the primary group, who is the best person(s) to talk to at RTI and within our follow-up group about the sample size/Bayley 3 questions for the Support trial so I can best understand the issues?

Thanks.

Yvonne

Subject: supplemental SUPPORT MRI white matter summary classification form
Date: Tuesday, May 26, 2009 5:59:28 PM
Attachments: SUPPORT_MRI_Supplemental.docx

Hi all,

Attached is the supplemental SUPPORT MRI white matter injury summary classification form. Kris, I know this is probably coming out of left field for you. Rose and Abhik and I discussed it in a few emails when I was trying to get an idea of whether we really could or should do this.

Here is the issue in a nutshell: There have been an increasing number of papers reporting more than one MRI reader to establish reliability/agreement - and this was particularly evident at the recent PAS. Also, we have 2 central readers for the CUS. So, it is now becoming painfully clear that we need to have at least a SAMPLE of the 500 MRI's read by another neuroradiologist. Abhik and Rose and I have discussed using a streamlined summary classification form rather than trying to have the 2nd reader go through ALL of the very detailed MRI central reader form. Thus, our "main" central reader Dr. Barnes would fill out this supplemental form and the central reader from, while the 2nd central reader would only fill this form - we could ascertain concordance using this supplemental form.

Based on some calculations that Abhik did for me, we would probably need the 2nd reader to read 80-100 randomly selected MRI's to establish agreement.

So - long story - this attached is the supplemental form, already "OK'd" by Dr. Barnes. I am gathering some names of potential 2nd central readers (I have gotten a couple names already from Dr. Slovis, I have asked Dr. Barnes, and I will ask one other person I know in UCSF for names).

Kris - can you make this into a "real" form? However you magically do that... Abhik and Kris - note that in A.2, I indicate that the ACTUAL SCORE (numerical) should be entered in the box. This won't be a problem from the perspective of data entry, correct?

Thanks

Susan

A. SUMMARY CLASSIFICATIONS: WHITE MATTER INJURY IN PRETERM INFANTS

A.1 Miller Classifications; Check one box for each hemisphere	Normal	Minimal	Moderate	Severe	Not interpretable
Right					
Left					

KEY: Miller Classifications (ref 1-3)	NOTE per Miller, et. al. (UCSF group) **WM abnormalities included foci of abnormal T1 hyperintensity in the absence of marked T2 hypointensity in the periventricular area. The constellation of T1 hyperintensity in the absence of T2 hypointensity most likely represented areas of gliosis. Areas of cavitation also included**
Normal	No WM lesions
Minimal	3 or fewer areas of T1 signal abnormality measuring <2 mm
Moderate	3 or more areas of T1 signal abnormality or these areas measuring < 2 mm but >5% of hemisphere involved
Severe	>5% of hemisphere involved

A.2 Inder Classifications; Enter score in appropriate box for each hemisphere	Normal (5-6)	Mild (7-9)	Moderate (10-12)	Severe (13-15)	Not interpretable
Right					
Left					

Key: Inder Classifications (ref 4-6)	**Score = 1**	**Score =2**	**Score =3**
1) WM signal abnormalities (on axial imaging)	Normal T1 and T2 throughout	Focal regions of high T1 or T2 signal (2 or fewer regions per hemisphere)	Multiple regions of high T1 or T2 signal (> 2 regions per hemisphere)
2) Perventricular WM volume loss (axial and sagittal) – looking at ratio of periventric WM to vent volume	Normal PV WM volume	Mild reduction in WM volume with mild-mod vent size increase	Marked reduction in WM volume often with marked increase in size of vent or extra-ax space
3) Cystic abnormalities	Normal	< 2 mm single focal cyst	Multiple cysts or a single large (>2 mm) focal cyst
4) Ventricular dilatation (axial and sagittal)	Normal with no vent dilation	Mod enlargement resulting in mild rounding of front horns, minimal enlargement of temporal horns and mod enlarge of occipital horns	Global enlargement of a moderate to severe nature
5) Thinning of the CC (sagittal and coronal T1)	Normal, thick CC	Focal thinning of the CC often visible in mid region of CC	Global thinning

The sample size calculations in the SUPPORT protocol also mention the follow up outcome of death or NDI, though the primary outcomes are death or BPD and death or ROP. (Page 24 of the protocol states: "Thus the actual sample size for this trial would be 1310 for 80% power for detecting an absolute difference of 10% in the two primary outcomes and the NDI secondary outcome.") Of course, these were based on the Bayley II and may not obtain for the Bayley III. I am happy to discuss this issue as well.

Thanks

Abhik

Hi Rose,
This little one is still hospitalized and will hopefully be discharged (b) (6) At status the NG03 and NG07 will be entered along with the entire SUPPORT chart.
At 36 weeks she was intubated and on conventional ventilation post PDA ligation. Unfortunately it took her a week to extubate to Hudson CPAP.
If things continue to go well for her, I think her info will be entered by the end of the month.
Have a great Memorial Day.

SUPPORT Oximeter by Center Home 20080131.pdf

Dear all,

Just a reminder to let me know when you have received all your original oximeters from other centers so that we can coordinate a convenient time for the Massimo rep to come to your site to convert your oximeters.
Thanks,
Kris

Subject: Support Trial Oximeter Returns

Dear all,

Now that the Support trial has completed enrollment and as your remaining infants complete the study per protocol; please return the study Masimo oximeters to their original institutions (Oximeter owner in the attached pdf file). Please also find attached an updated address list (Support Coordinator file attached) to include addresses for Miami, Wake Forest, Rochester and UCSD. Please clean all equipment and include sensors and probes prior to sending them home. For those oximeters currently being repaired at Masimo, please send the original institution an email listing the serial number being repaired and send that oximeter on once received back from Masimo.

Thank you all very much,
Kris

Hi Rose,
We have resloved the outstanding missing data form SUPPORT. We have informed the mother of subject (b) (6) to see an ophthalmologist and awaiting to hear from subject's mother.

Thanks,

Hi Rose

I am forwarding this to you to think about with me. Jane was trying to be inclusive and asked Chuck Green for input as to order of tests, need for breaks, etc for the 6-7 year SUPPORT follow-up. This is what she got in return. I have not (and do not plan to) respond to this. Read especially email #1.

Other psychologists in the Network have been very helpful and supportive, and we have had a lot of input (including international) on this.

Let me know what you think. I told Jane not to worry about it for now - and not to rock the boat further. We may just choose to ignore the whole thing - that might be best.

Susan

Chuck has a slightly different way of approaching things. You will want to read through e-mail #1. I didn't respond to it and then I got e-mail #2. I didn't respond to that one either.

I don't want to alienate Jon Tyson, so just let me know how you would like to handle this. I've been out of the office so I do have an excuse for not responding to him earlier !

No. Your e-mail was perfectly clear. The protocol is characterized as lengthy and intense in your original e-mail. I will not comment on either the appropriateness of the battery or its ordering unless I know the specific hypotheses for testing referral. I cannot provide input without that information. I either expect it to be furnished, or I expect not to be asked.

Sorry – I guess my e-mail wasn't clear. Based on your experience in a clinic setting with kids, we are looking for your input on order of administration and breaks – things that would help the visit progress smoothly. Also, if you have suggestions on how to arrange the parent questionnaires, we would like to hear that too.

Jane,

The planned tests are really quite broad in scope. If possible could I have a set of the specific hypotheses for the study? In particular it would be helpful to have hypotheses related to both brain structure and function.

Thanks,

Chuck

Hi Charles

As you know, the NRN SUPPORT Trial group is doing a follow-up study of kids in the 6-7 yr old range. Susan Hintz, the study PI, and I would appreciate it if you would review this grid *for the proposed order of the tests.* It is clear that we will need to have a substantial break for the children - like a lunch break - given the length and intensity of the testing, but we would like your input on order of admin, breaks, etc. based on your experience. The parent questionnaires can be administered simultaneously with the child testing. These questionnaires are not in any particular order right now, but perhaps you have suggestions on that.

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

If you could let me know your thoughts in the next couple days, that would be great. I am compiling comments from the gold standard folks from the HIE study and will send everything on to Susan.

Thanks
Jane

Subject: RE: Support Trial Protocol

On reflection I think my e-mail was a bit abrupt. I still require the information to provide my input, but I want you to understand why. Cognitive assessments are done to obtain a sample of behavior from a child in order to infer to the "population" of that child's behavior. This is very similar to the type of reasoning applied in inferential statistics. In so far as the sample of the child's behavior is representative of the population, accurate inferences are possible. Anything that degrades the sample of child behavior by definition degrades the inferences. These things include fatigue, external noise and distractions, in short anything that interferes with the cognitive processing under investigation. It is important to organize testing in two ways: 1) to systematically vector in on the cognitive function in question, ruling out other process that may be confounding inference, and 2) to prioritize testing such that the most highly valued data is gathered prior to inevitable degradation of performance due to fatigue. Further, depending on the hypotheses other cognitive processing, effects should be considered that might bias interpretation of norms. It might be that all batteries follow the same ordering....it might be that there are scenarios where counterbalancing order across participants is of interest. Finally, depending on what cognitive functions are of interest there may be a pre-defined order of administration that is required.

The completed NG03 and NG07 forms aren't technically expected until the patient reaches status (120 days, death or discharge), but the PHY01 form is expected on the 36 week date of the patient. For Support patients, this form is still required, so she should be getting this information regarding BPD at the 36 week date and thus could complete it out in the NG03 and NG07 data.

Let me know if this prompts any further questions.

Hi. I am a bit confused as to why the network is expecting data (NG03 and NG07) on infants because they have reached 36 weeks. Both of these forms are unable to be completed until the pt is discharged or has reached 120 days. Am I not understanding what you are expecting?

(b) (6) -Pt has been "no show" for ROP visits. They are still working on getting them in. We are awaiting one ROP visit outcome which should be arriving soon from 2008, but we do not think it will be the final one.
(b) (6) -BPD challenge being entered and have chart has been ordered for ROP status
(b) (6) -Infant is still in the hospital
(b) (6) -Infant is still in the hospital
(b) (6) -Data has been entered
(b) (6) -Infant is still in the hospital
(b) (6) -Data has been entered

I have entered all the current info that I have. There seems to be an issue with our tranmission of data that we are working on. So, in a nutshell. Patient(b) (6) was lost to follow-up, therefore N was entered on the Supp 10 form. Same for patient(b) (6). I corrected patient(b) (6) to reflect that the infant was on RA, no cannula or cpap at 36 weeks, but went on to be discharged on oxygen. The NGO7 will show this info. I am still trying one more thing for Patient(b) (6) for ROP status. So, as soon as we are able to trasmit, the info will be there. Sorry for the delays. Renee

Rose,
Has been a fairly constructive day and I'm making progress. See my comments below. Will let you know as I progress.
Thanks for all your help,
Ellen

Hi,

We are missing the following SUPPORT primary outcomes and would like to be able to perform that analysis shortly after the final patients reach status. Please promptly attend to these missing data elements.

I was aware of a transmission problem from your site – let me know if this is still a problem.

Thanks for all your hard work.

Rose

Yes, he turned up 3 days later.
A neighbor told her to scatter kitty litter from the litter box in the yard so he could recognize the scent and find the house.
He showed up about 6 hours later!

Thanks for asking!
Bonnie

Subject: 4 22 SUPPORT Growth Sec Possible Tables_Figures_Analysis
Date: Thursday, April 23, 2009 1:17:42 PM
Attachments: 4 22 SUPPORT Growth Sec Possible Tables_Figures_Analysis.docx

Hi all,

Good to be on the call yesterday. As promised, here is an outline of the analytical plan, with questions at appropriate points. Please let the sub-committee see the suggested analysis plan and let us have your feedback. As mentioned yesterday, your expected timeline for analysis to begin is towards the end of summer.

Thanks
Shahnaz

SUPPORT: GROWTH SECONDARY STUDY

Oxygen Saturation Arm (randomized from birth, stratified into 24-25 and 26-27w):

- LOW Saturation = 85-89%
- HIGH Saturation= 91-95%

Hypotheses
PRIMARY Low O_2saturation infants better short AND long term growth
PRIMARY Low O_2saturation infants better in-hospital growth trajectory
SECONDARY Independent of saturation group, infants >50% time daily median sats within 85-95% better growth (while on supplemental O2) [redacted]
SECONDARY Independent of saturation group, infants with BPD poorer short and long term growth
SECONDARY Independent of saturation group, positive correlation between better long term growth and better ND outcome

Specific Aims	Data
1. To determine anthropometric measurements (wt, HC, length) in infants randomized to low and high oxygen saturation arms, from birth to hospital discharge and again at 18-22 months corrected age	Weight, HC, Length at: Birth day 7 day 14 day 21 day 28 32wk PMA 36wk PMA OR discharge 18-22month follow-up
2. To determine nutritional intake (parenteral and enteral) during hospital stay	24h intake (enteral/parenteral): volume and composition (kcal/kg/d) day 7 day 14 day 21 day 28 32wk PMA 36wk PMA OR discharge
3. To determine the percentage of infants with growth <10 percentile at 36 weeks PMA or discharge, whichever comes first	<10th%ile at PMA 36 OR discharge

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

	(proposed reference growth curve: NICHD 1999 Ehrenkranz postnatal growth curves)
4. To determine the percentage of infants with growth <10 percentile at 18-22 months corrected age	<10th%ile at 18-22month follow-up (proposed reference growth curve: NCHS/CDC)
5. To determine in-hospital growth velocity/trajectory in low and high saturation arms	Antropometrics from birth to PMA 36 OR discharge (6 time points)OR between EACH measurement period WT: gain of grams/day HC: gain of cm/week Length: gain of cm/week *need time interval from birth to PMA 36w or discharge *time interval from 28d and 32wk WILL BE DIFFERENT ACCORDING TO GA AT BIRTH
6. To determine long-term growth velocity/trajectory, from hospital discharge to follow up at 18-22 months corrected age in low and high saturation arms	Antropometrics at discharge and 18-22m FU (2 time points) *need time interval from discharge to 18-22m FU WILL BE DIFFERENT FOR EACH
7. To determine growth in relation to the proportion of time spent with oxygen saturation a. <85% and >95% (out of range) b. 85-95% (within range)	Subanalysis of the two groups: Combine exposure groups and then split each according to 1. >50% of time within range 2. <50% of time within range
8. To determine growth in relation to the proportion of infants with a. Median SpO2>95% b. Median SpO2 between 85-95% c. Median SpO2 <85%	Subanalysis of the two groups: Combine exposure groups and then split to overall saturation median value a. Higher than upper limit

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

	b. Within range c. Lower than lower limit
9. To relate incidence of BPD in low and high saturation arms to growth	Subanalysis of the two groups: a. BPD b. No BPD
10. To relate neuro-developmental outcome at 18-22 months corrected age to long-term growth in low and high saturation arms	Change in anthropometrics and Neurodevelopmental measures (Bayley III: cognitive, language, motor)

POPULATION:

SUPPORT Cohort minus ~300 (enrolled prior to initiation of secondary),

?+/- deaths prior to 36wk/ discharge (short term analysis)

?minus lost to follow-up (long term analysis) +/- deaths

TABLE: POPULATION CHARACTERISTICS (GDB data)

Population Characteristics:	LOW Saturation	HIGH Saturation	Statistic Comparison
N			
Birth weight			t test
Gestational Age			t test
%SGA			Chi-square
Head Circumference at birth <10%			Chi-square
Length at birth <10%			Chi-square
Race (black, not black)			Chi-square
Multiple birth (yes, no)			Chi-square
Antenatal steroids (yes, no)			Chi-square
Method of delivery (SVD, not SVD)			Chi-square
Mother education: HS grad (yes, no)			Chi-square

TABLE: CLINICAL CHARACTERISTICS (GDB and SUPPORT data)

Clinical Characteristics:	LOW Saturation	HIGH Saturation	Statistic Comparison
N			
RDS (yes, no)			Chi-square
BPD (yes, no)			Chi-square

GROWTH:

- Short Term = in hospital (*need time interval from birth to PMA 36w or discharge)
- Long Term = 18-22m follow-up (*need time interval from discharge to 18-22m F/U)

DEFINITION OF GROWTH:

Most commonly used measure for growth failure is <10th %ile at each time point; therefore, growth may be defined as any parameter ≥10th %ile

BOOST uses <10th%ile for wt and L and <3rd%ile for HC (in comparison to NCHS growth curves)

Glutamine Growth 2005 <10th and 5th%ile

Velocity= difference of parameter between two (adjacent) time points and divided by the number of days between the measurements. What is the definition of good growth velocity? Standard definitions of accepted wt gain 15/kg/day or L and HC gain 0.9cm/wk

STOP-ROP uses change in growth parameter between two time points (absolute value)

NICHD (Ehrenkranz 1999) provides growth velocity by BW intervals

Standard Deviation Score for each time point

PN malnutrition (Embleton 2001) uses change in z-score (in relation to birth z score)

NICHD (Ehrenkranz 1999) also provides average body weight vs. PMA in weeks

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

WHICH REFERENCE GROWTH CHART TO USE?

In-hospital:

Ehrenkranz 1999 NICHD longitudinal postnatal growth chart: 1994-1995 501-1500g up to 120d (n=1660)

Fenton 2003 (fetal-infant chart: meta-analysis or combination of published fetal reference charts and smoothed onto the CDC term infant chart)

(Glutamine Growth 2006: used Alexander as growth reference)

Long-term 18-22m F/U:

NCHS (National Center for Health Statistics) aka.CDC

(NICHD Glutamine Growth 2006: used NCHS as growth reference)

(NICHD Infection and Growth/ND 2004: used NCHS as growth reference)

Subject: SUPPORT two-site ancillary

Hi,
Attached is a **confidential** proposal from Drs. Martin and DiFiore to look at desaturations and ROP from the SUPPORT trial oximeters at UCSD and Rainbow Babies. Michele had mentioned this study on our last conference call.
There are currently SUPPORT trial oxygen saturation data in 95 infants from the Cleveland site and 14 potential infants from the San Diego site with 2 second resolution. As described in the grant proposal entitled *INTERMITTENT HYPOXIA AND RETINOPATHY OF PREMATURITY*, the investigators are requesting access to the randomization assignment for these infants. In addition, they are requesting the software code (from RTI or Masimo) to correct the modified/blinded SaO2 data back to the true values. If this software is not available, they will need access to the documentation containing the details of how the points were modified. This information will be needed to write the software code at our site.

PLEASE SEND ME A YES/NO VOTE by April 20 to allow submission of the proposal with the caveat that the primary paper(s) be accepted for publication prior to any release of information.

Thanks
Rose

Subject: RE: SUPPORT two-site ancillary
Just to be clear: we are asking for a letter of support from the NRN steering committee
That states if an R21 submission to develop methodologies is funded, there would be access to this data set.
The goal is to develop better methods for analyzing
the complex data contained in the saturation files:
Should one time average, is it better to look at the lowest sat, highest sat,
Are swings in saturation more meaningful, etc.
No specific hypotheses would be tested in this methodologic work-
Rather it is just to advance the field's methods for analyzing this complex data.
WE have 82 patients that were not in SUPPORT. WE would utilize the SUPPORT data
Set for testing after we develop methods in the non-SUPPORT cohort.
Thanks!

I vote YES.

I am concerned about bias but I think they should be encouraged to study this. There should be a much more specific hypothesis as well as many very well pre-specified hypotheses as they want rather than exploratory analyses.

Subject: SUPPORT two-site ancillary

Hi,
Attached is a **confidential** proposal from Drs. Martin and DiFiore to look at desaturations and ROP from the SUPPORT trial oximeters at UCSD and Rainbow Babies. Michele had mentioned this study on our last conference call.
There are currently SUPPORT trial oxygen saturation data in 95 infants from the Cleveland site and 14 potential infants from the San Diego site with 2 second resolution. As described in the grant proposal entitled *INTERMITTENT HYPOXIA AND RETINOPATHY OF PREMATURITY*, the investigators are requesting access to the randomization assignment for these infants. In addition, they are requesting the software code (from RTI or Masimo) to correct the modified/blinded SaO2 data back to the true values. If this software is not available, they will need access to the documentation containing the details of how the points were modified. This information will be needed to write the software code at our site.

PLEASE SEND ME A YES/NO VOTE by April 20 to allow submission of the proposal with the caveat that the primary paper(s) be accepted for publication prior to any release of information.

Thanks
Rose

Neil,

It could be that some of the 21 infants without NG03s still have not reached status. However, I can add reminders for the centers to enter the NG03s and NG07s to the list Rose sends out every 2 weeks, especially if birth occurred over 120 days ago.

Hi Marie

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

It looks like # 3 in your attachment accounts for the majority of concerns – ie the 21 infants with no NGO3. We need clarity on these infants.

Any Baby with a Diagnosis of BPD does not require further so I would not add the infants in your #2 to the missing BPD outcomes list.

Thanks Marie

Neil

Subject: SUPPORT infants with missing BPD or ROP

Neil and Rose,

Attached is a document with details on infants missing BPD and ROP outcomes, including reasons the outcome is missing, current PMA and, for ROP, status and PMA at last exam.

There are a couple of things to note regarding missing BPD:

1) Currently there are 21 infants who have survived to 12 hours but who do not have a form NG03 entered. For the missing outcomes lists I have been sending to Rose, I have been keying off of the NG03; thus, these infants have not received missing BPD reminders. However, I can add them to the list if you wish.
2) There are some infants who should have a PHY01 based on their NG07 36 week snapshot data but who have a default BPD determination based on the NG07 (for example, if they were on vent or CPAP at 36 weeks then BPD=Y). These infants have not been receiving missing BPD reminders, and they do not appear on the attached list, because they have a BPD status based on the NG07. They have, however, been receiving missing forms reports from Jenny every two weeks to remind them that the PHY01 is expected. If you would like me to add these reminders to the missing BPD reminders that Rose sends out, I can do that.

Subject: Re: CUS Central Reading

Hi all,

I am forwarding this to Drs. Bulas and Slovis - the email below pertains to how Dr. Barnes like the MRI's "packaged", so perhaps the central readers would like to weigh in on how they would like things set up.

Dorothy and Tom - for the MRI's, we have been individually "packaging" the disks of the imaging - along with a central reader form pre-populated with some of the data at the header - in a 9x12 envelope with the description of what the imaging is (in that case SUPPORT MRI, but in your case it would be SUPPORT CUS), NRN center #, patient #, and date imaging done. Then, Dr. Barnes has been "signing off" the front of the envelope when done.

If this sounds good to you as a way to pre-package the studies, we should alter it in the following way:

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

1) Prepopulate TWO central reader forms and put them in the envelope along with the disk of the CUS

2) The envelope would be labeled "SUPPORT CUS", not SUPPORT MRI

3) When you read, the RTI assistant would take the form and disk out of the envelope, making sure not to show you the other form (i.e., if it's filled out by the other reader already). When you have completed reading, the RTI assistant or you could initial the front of the envelope - by the end, we would have 2 sign-offs on each envelope.

At least it would all be neatly packaged - but weigh in if you would like it some other way.

**The other question that has come up is in the header of the CUS central reader form (ATTACHED), question 3 - the question is "Reading" (not Reader, which is a different question). This same thing was on the PiNO CUS central reader form, and for the life of me I can't remember what it was for - was this for the initials of the RTI assistant that marked the form while the central reader read?? Dorothy, Tom or Carolyn - do you remember?

Thanks,

Susan

Hi Dr. Hintz,

I am working on getting all the materials for CUS central reading setup. Kris forwarded me the message below, is this how you would like the materials setup for the central reading? If you have any other requests, please let me know.

I am also going to attach forms to each CUS and pre-populate the following information:

Center

Network #

Reader

Date Read

Date of Sonogram

However, question 3 under section A is **Reading**. What information are we collecting in this field? Is this something that can be pre-populated on the form? Attached is the form for your reference.

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

Subject: Re: Support MRI secondary images for central reading

Yes, they should be sent asap. HOWEVER, before you start sending, I would love it if you could "package" them there the way Dr. Barnes likes it before you send them to me. Up to now, I have done it, but I simply don't have the time or support to do it now. This "packaging" is something he and I developed to make sure everything stays in the right place, and to make it as easy as possible for him to read efficiently. The process involves putting each individual CD along with a MRI scoring form *already marked with the patient number, site and date of exam on BOTH pages of the scoring form* in a 8x11 or 9x12 manila or white envelope Then, I label the front of the envelope with the title "SUPPORT MRI study", the patient study ID, the site #, the date of the MRI. So - I could take a picture of the front of the envelope and send it to you.

Also - do you have the newest version of the SUPPORT MRI scoring forms and key?

Thanks - let me know

Susan

Hi Susan,

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

Now that Dr. Barnes has completed the Hypothermia MRI central readings do have a timeline for when you and Dr. Barnes would like to start receiving the Support MRIs?

Thanks,

Kris

From: Gantz, Marie
To: Finer, Neil; Higgins, Rosemary (NIH/NICHD) [E]
Subject: SUPPORT infants with missing BPD or ROP
Date: Thursday, April 02, 2009 5:19:04 PM
Attachments: SUPPORT infants with missing BPD or ROP 04-02-09.rtf

---

Neil and Rose,

Attached is a document with details on infants missing BPD and ROP outcomes, including reasons the outcome is missing, current PMA and, for ROP, status and PMA at last exam.

There are a couple of things to note regarding missing BPD:

1) Currently there are 21 infants who have survived to 12 hours but who do not have a form NG03 entered. For the missing outcomes lists I have been sending to Rose, I have been keying off of the NG03; thus, these infants have not received missing BPD reminders. However, I can add them to the list if you wish.
2) There are some infants who should have a PHY01 based on their NG07 36 week snapshot data but who have a default BPD determination based on the NG07 (for example, if they were on vent or CPAP at 36 weeks then BPD=Y). These infants have not been receiving missing BPD reminders, and they do not appear on the attached list, because they have a BPD status based on the NG07. They have, however, been receiving missing forms reports from Jenny every two weeks to remind them that the PHY01 is expected. If you would like me to add these reminders to the missing BPD reminders that Rose sends out, I can do that.

Marie

Reasons BPD is missing

The FREQ Procedure

Reason no BPD classification				
nobpdreason	Frequency	Percent	Cumulative Frequency	Cumulative Percent
0=NG02 not entered	8	11.43	8	11.43
1=Infant < 37 weeks PMA	37	52.86	45	64.29
2=survival to 12 hours temporarily missing on NG02	1	1.43	46	65.71
3=Infant alive at 12 hours but NG03 and NG07 not entered	21	30.00	67	95.71
4=Infant in hospital at 36 weeks but NG07 not entered	1	1.43	68	97.14
5=NG07 36 week snapshot missing data on FiO2 and RA by NC/CPAP/vent	1	1.43	69	98.57
6=Eligible for challenge per PHY01 but no PHY02RA result	1	1.43	70	100.00

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

The FREQ Procedure

Reason no BPD classification=0=NG02 not entered

	Current estimated PMA			
Group	Frequency	Percent	Cumulative Frequency	Cumulative Percent
	8	100.00	8	100.00

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

The FREQ Procedure

Reason no BPD classification=1=Infant <=37 weeks PMA

	Current estimated PMA			
estage	Frequency	Percent	Cumulative Frequency	Cumulative Percent
29	1	2.70	1	2.70
30	2	5.41	3	8.11
31	5	13.51	8	21.62
32	4	10.81	12	32.43
33	1	2.70	13	35.14
34	10	27.03	23	62.16
35	10	27.03	33	89.19
36	2	5.41	35	94.59
37	2	5.41	37	100.00

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

The FREQ Procedure

Reason no BPD classification=2=Survival to 12 hours temporarily missing on NG02

Current estimated PMA				
Level	Frequency	Percent	Cumulative Frequency	Cumulative Percent
24	1	100.00	1	100.00

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

The FREQ Procedure

Reason no BPD classification=3=Infant alive at 12 hours but NG03 and NG07 not entered

	Current estimated PMA			
CStage	Frequency	Percent	Cumulative Frequency	Cumulative Percent
38	3	14.29	3	14.29
39	4	19.05	7	33.33
40	3	14.29	10	47.62
41	2	9.52	12	57.14
42	2	9.52	14	66.67
43	2	9.52	16	76.19
45	2	9.52	18	85.71
46	1	4.76	19	90.48

Hi Angelita,

Because the NG07 data indicate that infant (b) (6) was on room air by NC at 36 weeks, the PHY01 is actually expected per technical memo SUP14. Any time section C is completed on the NG07, infants enrolled in SUPPORT should have the PHY forms entered in the DMS.

Let me know if you have any questions.

Thanks,
Marie

Subject: RE: SUPPORT

Hi Rose,

(b) (6) - was seen for the 18 month visit in Follow up on (b) (6). We have contacted the ophthalmologist and are awaiting the final results from him.

(b) (6) was born on (b) (6) and per the SUP14 Technical memo does not need the PHY01 form. The NG07 was entered on 3/13/09.

(b) (6) - this family has moved to Indiana. The Indiana site F/U PI and coordinator were e-mailed on 1/20/09 and Vicky also spoke to the coordinator there on 2/3/09. As of this morning no contact had been attempted with the family. Suzy called the Indiana Follow up coordinator again and she was going to get back to her today. We will keep checking.

Angelita

Hi,
We are missing a few SUPPORT outcomes. Let us know how you are doing,
Given the spectacular recruitment from your site, this is amazing!!!!
Thanks
Rose

Hi Rose,
We were able to obtain additional outpatient eye exam results on 7533 1 and now final status was reached with 2 consecutive eye exams in zone 3 with stage 3 regressed ou. We are still trying to contact 7530 1 who was transferred to another hospital and was not scheduled to return for followup exam until 8-12 months old. thanks,
Monica

Jenny and I looked into this, and it turns out that NF forms were entered for the infants instead of SF forms (intended for SUPPORT infants not in GDB). Jenny will contact UCSD to resolve that issue, but it does look like we have the data.

Subject: RE: SUPPORT and retinopathy

I wrote a brief proposal for this in Oct 2007 after Dale and I discussed it (attached). I really thought it needed some input from an ophthalmologist (see questions in red) so I sent it Helen Hittner (our ophthalmologist). She had initially expressed interest and then never responded (got busy with the Avastin study). I also got the impression that Dale wasn't very interested so I let it drop. I'd be happy to pick it up and do most of the work if Dale and Neil are interested. Maybe Dale could answer the questions that I posed to Helen in the attachement.

Subject: SUPPORT and retinopathy

Dale and Kathleen

The SUPPORT subcommittee met today to discuss data analysis. I recall that there was some discussion with the two of you regarding a "natural history" analysis of the ROP exams. Let me know if there is still interest in this as we had not received any secondary proposal to perform this analysis.

Thanks
Rose

Retinopathy of Prematurity (ROP) Natural History Study
Secondary Study for SUPPORT Trial

Kathleen A, Kennedy, MD, MPH and Helen Mintz-Hittner, MD

Introduction and Rationale

Timely detection of treatable ROP is important to assure optimal outcomes for infants who meet the current criteria for treatment. The most recently published screening guidelines[1] are based on natural history data from the CRYO-ROP[2] and LIGHT-ROP[3] studies. The CRYO-ROP study[4] remains the most carefully conducted analysis of the incidence and timing of the onset of ROP, although it was conducted over 20 years ago (1986-1987). The LIGHT-ROP study enrolled infants from 1995-1997.[5] Over the past two decades, survival of lower gestational age infants has increased.[6] For infants 501-1000 g birth weight, survival increased from 41% in 1990-1991 to 55% in 1997-2002. The timing of onset of ROP is related to both gestational age and postnatal age. The impact of increased survival on the incidence and timing of onset of ROP has not been systematically evaluated.

In the CRYO-ROP and LIGHT-ROP studies, treatment was initiated for threshold ROP (now termed "old threshold"). Based on the results of ET-ROP study, earlier treatment (now termed "new threshold") is now recommended.[7] In the ET-ROP study, 60% of the infants with pre-threshold ROP (by the conventional definition used in the CRYO-ROP study) met the high-risk pre-threshold criteria for this earlier "new threshold" treatment. Based on these new treatment criteria, screening must now be initiated early enough to reliably identify infants with high-risk pre-threshold, rather than "old threshold", ROP. In the CRYO-ROP study, for infants <750 g, ROP (any severity) occurred in 90% and reached pre-threshold in 39%. In 750-999 g infants ROP occurred in 78% and reached pre-threshold in 21%. In the <750 g infants, less than 5% of infants who reached pre-threshold ROP did so by 32.3 weeks postmenstrual age; in 750-999 g infants, <5% of those who reached pre-threshold ROP did so by 32.6 weeks postmenstrual age. In this study, <1% of infants who reached pre-threshold ROP did so by 30.9 weeks postmenstrual age.

In addition to information about when screening must begin, clinicians need information about when the baby is no longer at risk of treatable ROP so that appropriate follow-up can be arranged (particularly for infants who have been discharged from the hospital) or attempts to arrange follow-up can be curtailed. In the CRYO-ROP study, 99% of the infants who reached the threshold ROP criteria had done so by 45.9 weeks postmenstrual age. Helen, can we assume that treatment initiated after this would not be beneficial? It seems to me that there must be some window after this during which treatment is worth considering. We're mainly talking about babies who were lost to follow-up so you don't know what happened in the interim, but you want to stop looking for them.

In the NICHD Network SUPPORT trial, severe ROP (threshold or need for surgery) is the primary outcome for the O_2 saturation target arm of the factorial design. For this study, extensive ROP outcome data, in addition to the ROP outcome data routinely collected for the GDB, is being prospectively collected for all enrolled infants. Infants 24 0/7 – 26 6/7 weeks gestation are eligible for this study. A sample size of 1310 infants is planned. For enrolled infants who survive until the first eye exam, the following data are recorded at each eye exam: the date of the eye exam, the highest stage and lowest zone of ROP, whether the infant met the criteria for "new threshold" ROP using the new ET-ROP definition, and whether treatment was administered. Examinations are continued according to current non-study screening recommendations: until either vascularization has reached zone 3, the infants is 45 weeks postmenstrual age without prethreshold ROP, or ROP has regressed. These data will allow us to track the distribution of postnatal age and postmenstrual age at which treatable ROP occurs, using the new criteria for treatment and current survival demographics. Helen, do you think it's worth the effort if we're not going to have any data on babies < 24 weeks?

We will use the data collected for this trial to generate tables and possibly figures, similar to those published from the CRYO-ROP and ET-ROP studies[3], illustrating the distribution (with 1%, 5%, median, 95% and 99%iles) for the onset of ROP that meets the new threshold criteria for treatment.

Methods

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

Postmenstrual age will be calculated as gestational age at birth in weeks + days, using the Best Obstetrical estimate, plus the postnatal age in days at the time of exam. In cases where the findings differ between eyes, the age of onset will be recorded as the age at which the diagnostic criteria were met in the first eye. In the 2002 CRYO-ROP/LIGHT-ROP paper, the authors included the timing for onset in the second eye as well as the first eye that developed each criterion. Do you think that's necessary? It seems like it would be simpler to just record the time of onset for the first eye that met the criteria.

Analytic Plan

A Baseline Characteristics Table will include the following summary statistics for all enrolled infants and for infants who survived until the first eye exam: birth weight (mean, SD), gestational age (mean, SD), race (% by category), sex (% by category), multiple birth (% by category)

The following Outcome Table will be generated:

		Postmenstrual Age (weeks)					Postnatal Age (weeks)				
ROP	n	1%	5%	Median	95%	99%	1%	5%	Median	95%	99%
Prethreshold											
New Threshold											

Separate tables will be generated for each of the trial strata (24 – 25 6/7 weeks and 26 – 26 6/7 weeks). If the data are indistinguishable, they will be combined and reported in a single table.

Limitations

We cannot generate incidence data because only consented inborn infants are included. The inclusion criteria will not allow us to generalize to infants < 24 weeks gestation. (NG03 form from the GDB does not include any dates of onset.)

We need to find out how much of a problem we have with missing data.

A potential criticism is the lack of certified ROP examiners.

8.1.1 Analysis Plan

The primary analyses of this factorial trial will be a logistic regression analysis of the percent of each Group (Treatment vs Control, High vs Low SpO2) who developed their respective outcome measure (survival without BPD or ROP at 36 weeks respectively). An important analysis of a secondary outcome will determine if there is an effect of the interventions on the percent infants who survive without neurodevelopmental sequelae at 2 years For all secondary outcomes, univariate analysis for continuous variables will be performed using parametric (e.g., Student t tests, ANOVA), and non-parametric (e.g., Mann-Whitney U) tests where appropriate; categorical variables including the primary outcome, feasibility, will be examined by Chi square analysis. Analysis of covariance and multiple regression models will be used to examine the interaction between, and the independent effects of, various factors, (e.g., birth weight, gestational age, gender, treatment group, center, etc.) upon secondary outcomes (i.e., time to improvement in oxygen saturation, duration of positive pressure ventilation, five minute Apgar score, duration of mechanical ventilation, surfactant requirement, incidence of air leaks, and incidence of BPD).

Appendix A

Study Tables

Table 1. Patient Description

	Treatment	Control	P Value
Birth weight (grams) (M + SD)			
Gestation (weeks) (M + SD)			
Apgar 1 min < 3 Assigned			
Apgar 5 min < 3 Assigned			
Received PPV (Number, %)			
Surfactant in DR (Number, %)			
Received Chest Compression (N%)			
Received Epinephrine (N, %)			

Table 2. Other Outcomes

	Treatment	Control	P Value
Total Duration of Mechanical Vent (M +SD)			
Duration of Oxygen (Total days)			
Duration of CPAP			
Duration of nSIMV			
% alive off MV by Day 7 (+SD)			
Pneumothoraces (N, %)			
Other air leaks (N, %)			
BPD at 36 weeks (O_2 dependence)			
BPD by Physiologic Definition (N%+SD)			
Survived to discharge (N,% +SD)			
Number Never Intubated (N, %)			
Number receiving PNS for BPD (N, % %)			
Alive without neurdevelopmental impairment at (18-22 months) years (N, %, +/-SD)

The Business Case for Cost Effective Respiratory Management in the NICU (SUPPORT-Secondary Study)

Investigators: Vivek Narendran MD, MBA and Kurt Schibler MD

Background: Concern about high and rising health care costs in the United States has increased sharply in recent years. President Obama has made health care a priority, with a particular interest to decreasing costs and believes that it is no longer just a moral imperative, but a fiscal imperative to address this issue. Currently, the US health care spending is 16% of GDP and is projected to increase to 19.5% by 2017. In 2007, the US spent $ 2.26 trillion on health care or $ 7,439 per person up from $2.1 trillion or $ 7026 per capita, the previous year. *Technology,* not demographics or medical malpractice is the key driver of health care spending, accounting for an estimated half to two thirds of spending growth. Decision regarding respiratory support strategy is among the most critical choice impacting total cost for an ELBW in the NICU.

In this study, we propose to determine the incremental financial impact of different respiratory care practices in managing extremely low birth weight preterm infants. This retrospective study will include all patients enrolled in the NICHD neonatal network sponsored SUPPORT trial. By using this randomized cohort of infants, we intend to quantify the cost of different interventions and the financial impact resulting from preventing intubation and mechanical ventilation from multiple stakeholder perspectives, including third party payers. The data sources are the existing SUPPORT database and cost of care database of all the participating hospitals. The cost of care for all eligible infants from NICU admission to discharge home, death or 120 days of age (which ever occurs first) will be used to estimate average costs of infants on different respiratory strategies. We will facilitate collection of this data by collaborating with site PI's and financial analysts at different hospitals.

Primary Hypothesis:

1. We hypothesize that relative to infants managed with prophylactic/early surfactant and conventional ventilation that the use of early CPAP and a permissive ventilatory strategy in infants of less than 28 weeks gestation with continuing CPAP in the NICU *will result in decreased costs with similar outcomes.*
2. We hypothesize that relative to infants managed with a higher SpO2 range that the use of a lower SpO2 range (85% to 89%) *will result in decreased costs with similar outcomes.*

Subject:	MRI central reader form changes
Date:	Tuesday, March 17, 2009 6:33:48 PM
Attachments:	ChangesSUPPORTMRIcentral031609.doc

Hi all,

Dr. Barnes and I had a lengthy meeting yesterday to revise and finalize the SUPPORT MRI central reading form. The main issues are to make this a better, more complete document, and to create a form in which there is no temptation for written comments or extra marks, which would be impossible for the data entry folks to interpret. Some of the changes involve moving modified sections from the Hypothermia MRI form to the SUPPORT form, but others are based on Dr. Barnes' concerns about lack of clarity and quantitative measures in some areas of the Hypothermia forms.

Dr. Barnes knows that these changes mean he WILL NEED TO re-read the MRI's for SUPPORT already read. He also understands the time crunch - i.e., must be completed with time for data entry and analysis for the PAS 2010 late breaker abstract deadline. (I estimated that he needed to be completely done with the readings by August 2009 - that might be too fast, but rather an early than late deadline)

Attached are the changes. There will be another document to follow with changes to the KEY.

Thanks

Susan

Changes to SUPPORT MRI central reading form
March 16, 2009 Hintz

1) Section A: Identification

Please replace SUPPORT Section A with the Hypothermia Section A, but with the following change: A.4 should be "PMA in weeks and days at time of MRI". Dr. Barnes does not fill that in, but I assume that RTI will have an easy calculator for this question.

2) Section B: Signal Abnormalities

After the GRE column, please add a column for "DWI" and a column for "ADC"

3) Section C:

Section C.1.a – Gray matter maturation - This is OK – no changes needed
Section C.1.b – **Please replace this section with the following, which has been modified from Hypothermia section C.1.c:**

C.1.b Subarachnoid space: Measure space as indicated in millmeters, then assess space qualitatively *(normal, mild-moderate enlargement, marked enlargement).* NE=not evaluable

	Measure in mm	Normal	Mild-mod enlargement	Marked enlargement	NE
C.1.b.1 LEFT convexity	_ _ _ _				
C.1.b.2 RIGHT convexity	_ _ _ _				
C.1.b.3 ANTERIOR interhemispheric	_ _ _ _				
C.1.b.4 POSTERIOR interhemispheric	_ _ _ _				

Section C.2.a White matter maturation – this is OK – no changes needed

Section C.2.b – **Please replace this section with the following, which has been modified from Hypothermia section C.2.d and C.2.e**

C.2.b Corpus callosum regions. Measure indicated region of CC in millimeters (sagittal view), then assess thinness of region qualitatively (*normal, equivocal, marked).* NE=not evaluable

	Measure in mm	Normal	Mild-moderate	Marked	NE
C.2.b.1: genu	_ _ _ _				
C.2.b.2: body	_ _ _ _				
C.2.b.3: splenium	_ _ _ _				

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

Changes to SUPPORT MRI central reading form
March 16, 2009 Hintz

C.2.c QUALITATIVE assessment of overall corpus callosum thinness (check one box only)

	Normal	Mild	Moderate	Marked	NE
Overall CC					

Section C.2.c and C.2.d – **Please remove these sections and replace with the following, modified from Hypothermia sections C.2.g, C.2.f, and C.2.h:**

C.2.c. Lateral ventricle measurements. Measure indicated areas in millimeters

Potential awards for SUPPORT centers
MG 3-17-09

Wayne State

- Most improved enrollment. Site visit was in December 2006. Through December had enrolled 8 infants. From January 2007 to the present they enrolled 60 infants (88% of their total enrollment). The only centers that enrolled more during that time period were UAB and Brown.

Cincinnati

- Of the sites who recruited throughout the entire study, had the highest rate of multiples (32% of infants enrolled). 4th highest enroller overall. (Most efficient recruiter?)
- One of the lowest rates of protocol deviations at 10% of enrolled infants. Second only to UCSD who had 7%.

Houston

- 6th biggest recruiter overall, but did it the hard way, enrolling 80% singleton babies (highest rate of singletons among top enrollers, 3rd highest rate over all centers).

Emory

- 4th highest enrollment.
- No nasal breakdown reported (along with 8 other centers).

Duke

- 2nd highest rate of enrolling singletons with 83% (Dallas had 84%). 11th highest enrollment overall.
- 2nd highest rate of enrolling infants who were 24 weeks GA with 26% (Wayne State had 28%).
- No chest compressions reported.
- No nasal breakdown reported.

Utah

- 100% of BPD outcomes reported for infants who survived to 36 weeks (along with UNM, Wayne State and Dallas)

UNM

- 100% of BPD outcomes reported for infants who survived to 36 weeks.
- Most persistent: from Antenatal study, highest average number of attempts to obtain a consent (mean 3.5).
- Lowest overall rate of adverse events (33%).

3 Sites have 100% of ROP outcomes reported for survivors to 55 weeks PMA:

- Dallas
- Stanford
- Tufts

Developing Safe and Effective Instruments and Devices for Use in the Neonatal Intensive Care Units: A Workshop Summary

Abstract

In February 2009, the *Eunice Kennedy Shriver* National Institute of Child Health and Human Development (NICHD) of the National Institutes of Health (NIH) invited a team of experts to address the issues concerning the development of safe and effective instruments and devices for use in the neonatal intensive care units (NICU). Five topic areas were the focus of the discussions: 1) respiratory; 2) cardiovascular; 3) cerebrovascular; 4) metabolic; and 5) infections. Clinical needs, the status of current device/product technologies and their limitations, and future research opportunities were the crosscutting themes across topics. This paper provides a brief summary of the proceedings.

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

Neonatal Pulmonary Care

Delivery Room Equipment: Considering the wide range of medical and surgical conditions encountered during resuscitation of high-risk infants, it is surprising that much of the equipment being used in the delivery room has remained outdated. Some examples of emergencies requiring resuscitation in the delivery room include: preterm infants with immature lungs; meconium aspiration syndrome and persistent pulmonary hypertension; perinatal asphyxia; congenital diaphragmatic hernia; abdominal wall defects; and anomalies of the upper airways. Some immediate needs are: blenders to fine-tune administered oxygen concentration during resuscitation, ability to monitor pressure generated and tidal volumes delivered while providing intermittent positive air pressure ventilation (IPPV) or continuous positive airway pressure (CPAP); and devices to assess the adequacy of gas exchange ~~immediately after birth~~immediately after birth.

Assisted ventilation and oxygen supplementation, during transportation and in the NICU: Major advances in ventilatory support techniques and exogenous surfactant therapy in past two decades have led to marked increase in survival rates, especially for very low birth weight infants (VLBW, <1500 grams at birth). However, in contrast to older children and adults with lung diseases, most VLBW infants require ventilatory support for prolonged durations. ~~In one study, 80% of infants with birth weight <700 grams, and 50% with birth weights 700-1500 grams still required assisted ventilation on the 28th day.~~ Prolonged duration of assisted ventilation and supplemental oxygen markedly increases the risk for bronchopulmonary dysplasia (BPD) and Retinopathy of Prematurity (ROP). Depending upon the definition, the reported incidence of BPD in infants <1000 grams ranges between 44% to 75%. Since over 85% of such infants in this birth weight survive, a substantial number of infants and children will add to the pool of adults with pulmonary disability. ~~These infants also spend considerable periods of time above the intended ranges of arterial oxygen saturation which further increases the risk for BPD and retinopathy of prematurity.~~

The above data underscore the major clinical need for improving the quality of ventilatory support, with intent to reduce the duration of required assisted ventilatory support and to minimize ongoing lung injury. Such efforts require ~~more gentle~~gentler and less invasive modalities for respiratory support. Efforts need to begin by improving devices used in the delivery room resuscitation, and during transportation, since even a brief period of inappropriate ventilatory assistance can ~~cause~~ set a stage for ~~ongoing~~ progressive lung damage in premature infants.

In recent years, a number of new respiratory devices have been introduced for neonatal use; these are patient-triggered ventilators, in which synchronization results in larger tidal volumes with lower airway pressures. The limitations of these systems include, low sensitivity to trigger; delay in initiating a trigger breath; excessive sensitivity to artifacts (leaks or condensation of water in circuit); termination of inspiration too early causing insufficient tidal volume; initiating the trigger too late leading to extended

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

~~expiration~~inspiration; flow sensors adding dead space increasing CO2 retention. In addition, leaks around the endotracheal tube can cause auto cycling ~~poor~~ and poor estimation of tidal volume, with larger ~~delivery of~~ ventilator-delivered tidal volume compared the patient ~~delivered~~ tidal volume.

There is a variety of high frequency ventilatory (HFV) equipment, and their relative merits and limitations remain to be tested. ~~Besides such studies~~ In addition, HFV equipment for use during infant transport needs to be developed.

Among other newer modes of ventilatory systems are, non-invasive ventilation~~or~~ (NIMV); nasal continuous positive airway pressure (N-CPAP); and ~~the~~ neurally adjusted ventilatory assist (NAVA). ~~The~~ NAVA uses electrical signal from diaphragm via esophageal electrodes; much work needs to be done to assess the efficacy and safety of this ventilation modality.~~bring these devices to the market.~~

Some elements of an ideal ~~respirator~~ ventilator would be that it responds to changing physiological needs by automatic fine-tuning, rather than only when the caregiver pays attention to the patient. Such devices will assure that the patient spends more time at the ~~target~~ intended range of ventilation and arterial blood gases;. ~~with little if any time spent beyond the target range.~~ The ultimate goal ~~of developing~~ is the development of devices that will drastically reduce or eliminate chronic lung damage because of artificial ventilation, by reducing both the duration and extent of ventilatory support, and overcoming currently recognized deficiencies in ventilatory support systems.

Pulmonary Function Assessment: Currently available methods for assessing pulmonary function in the newborn infants include: chest radiograph; CT scan; respiratory induced plethysmography (RIP); helium dilution and nitrogen washout methods; body plelthysmograph; blood gas/acid base analyses as a proxy for adequacy of ventilation perfusion match and gas exchange. Each of the above method has limitations, and none is able to provide continuous information concerning changing pulmonary function status in sick newborn infants being treated with assisted ventilatory support. Thus, one of the most urgently felt needs by clinicians is the wide availability of simple bedside tools and methods for providing such vital information as adequacy of alveolar inflation, appropriateness of ventilation/perfusion match, and measures of barotraumas.

Other Aspects of Pulmonary Care: The endotracheal (ET) tube technology has not improved in over 20 years. This problem is acutely apparent while treating extremely small preterm infants whose tracheal internal diameter is often equal to the size of the smallest available ET tube. Their thick walls and small lumen lead to high resistance, and even minimal blockage due to respiratory secretions can lead to major reductions in flow volumes. While ET tubes without external cuff are used to avoid potential pressure injury to the trachea, with the advanced material bioengineering, it should be possible to produce pliable, but stiffer, ET tubes with thinner walls, allowing for enhanced internal diameter. Potential for developing leak-proof cuffs at least for use on an intermitted basis to assess pulmonary function would be valuable.

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

Ideal ET tubes may be considered to have the following characteristics: thinner walls to maximize luminal diameter; of sufficient rigidity to pass it through the glottis; with soft tips to avoid damage to the airways; visible on chest x-rays; with soft cuffs (intermittently inflatable) to minimize leaks; integrated CO2 detectors to help assess tube dislodgement; and with fiber optic lights at the end of the tube to visualize tube location without x-rays.

Collaboration and Education: It would be very beneficial for the device manufacturers to consult neonatologists and pulmonary experts input prior to prototype development on matters of clinical needs as well as design and compatibility of such products. Additional benefits could be gained by promoting trials to assess effects of new and existing devices and strategies on outcome. Academic societies may need to consider developing standard nomenclature for ventilator modalities, and education of personnel about use of the existing and new equipment.

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

Table I: New and Improved Devices/Equipment for use in Neonatal Respiratory Care

Area	Shortcomings and Needed Improvements
Resuscitation Equipment in the Delivery Room	• Generic devices: More efficient devices ~~providing~~ to provide CPAP (e.g., valves and bubbles); IPPV (self-inflating, flow inflating, interrupters, and T-Piece) need optimizing to meet specific types of ventilatory needs in the delivery room. • Gas Exchange: devices to assess adequacy of oxygenation and CO_2 elimination • Simple devices to monitor inspiratory and end-tidal pressures, delivered tidal volumes ~~or~~ and FRC • Improved air-oxygen blender set up in all delivery rooms to allow use of ~~FIO_2~~ FiO_2 at < 100% concentrations • Improving and standardizing all DR equipment in design and functionality
Respiratory support in the during transportation and in the NICU **Ventilators**	• *Patient-triggered ventilators*: avoiding leaks and other artifacts to prevent auto trigger at excessive ventilator rates; improving sensitivity and avoiding trigger delay and uncoordinated ventilator-to-patient cycle; and minimizing dead space. • *Volume targeted ventilation devices:* (e.g. volume control; volume guarantee; pressure regulated volume control, and volume assured pressure support): Eliminating leaks around the endotracheal tube, improving estimation of tidal volume; and minimizing volume loss in ventilatory circuits. • *High-Frequency Ventilators*: Comparative effectiveness research; improved HFV devices during transport
Non-Invasive Ventilation	• *Nasal CPAP and Nasal IMV*: Developing better nasal interfaces for nasal CPAP and non-invasive ventilation; assessing the advantages of synchronization; studies to demonstrate improved long-term outcomes.
Experimental Modalities	*Newer Devices*: ~~Distal tracheal ventilation~~ Distal tracheal ventilation and other methods to reduce dead space ventilation; target minute ventilation: automatic adjustment of ventilator rate to maintain total minute ventilation within target range; automated inspired oxygen control with automatic adjustment of FiO_2 to maintain O_2 saturation within a preset range.

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

Pulmonary Function Assessment and other pulmonary devices	• *Bedside assessment of lung volumes:* tools for assessing lung volume and pulmonary mechanics at the bedside, both intermittently and continuously; such measures could help minimize delivered tidal volume, estimate functional residual capacity, and help assess alveolar recruitment, over and under inflation, and ventilation-perfusion in-homogeneity. • *Electrical impedance tomography* –good research to understand what is actually being measured with these devices • *Improved endotracheal tubes* :thinner walls, larger internal lumen; soft enough to avoid airway injury, but firm enough to prevent kinking; with inflatable cuffs to prevent air leaks and help measure pulmonary functions; radio opaque; with fiber optic lights at the tip for accurate position assessment without x-rays; • Nasal laryngeal airways: currently these are too large for babies, but miniaturizing these would be ideal to address aspiration issue
Other Areas	• Developing "Smart alarms" for respiratory monitoring • Developing standard nomenclature for ventilator modalities • Neonatologists/pulmonary experts input prior to device development • Education of personnel about use of the existing and new equipment • Encourage research efforts to assess effects of new and existing devices or strategies on outcome

Hi Dorothy

Sounds good. If you and Tom could let us know what you think should be defined up front, and recommendations for the definitions, Kris and/or others can put together a key to go with the form.

Thanks again,

Susan

That is a very good idea. We can certainly put together a "key" for definitions as you suggest. But, if you and Tom want to make any changes to the SCORING FORM itself, the changes should really be done within the next week or so. The folks at RTI (data center) will be preparing the imaging including copying forms, filling out the header, and getting things together at the end of March/beginning of April for the central reading.

Thanks - let us know what you think about the scoring forms -

Susan

Subject: central reader CUS form - SUPPORT

Hi all,

Attached is what I have for the most recent cranial US central reader form - probably the last time we all looked at this was in 2005.

Dorothy and Tom - Do you have changes or suggestions to this form before the real fun begins? Please let us know what you think. Now would be the time to make any changes. I am also attaching the MRI central reader form and key for your interest -

Thanks again. It may sound strange, but I am looking forward to the central reading (part #1) in May!

Susan

MRI SCORING KEY (NOTE: All measurements in millimeter)

Revised January 23, 2008 (for SUPPORT)

C. MATURATION AND DEVELOPMENT

GRAY MATTER MATURATION [1, 2, 3]

For each hemisphere, mark level of maturation

Stage	Cortical maturation markers
G0	Frontal and occipital cortex completely smooth, insula widely open
G1	Frontal cortex still smooth, but some sluci in occipital cortex
G2	Frontal and occipital cortex with some convolutions, frontal sulci shallow
G3	Frontal and occipital cortex folded and rick in sulci, insula more convoluted and infolded
G4	Secondary gyri present transverse and inferior temporal; anterior and posterior orbit gyri
G5	Teritiary inferior temporal and infereior occipital gyri and sulci present. White matter now isointense with gray matter on T1
NE	Not Evaluable

SUBARACHNOID SPACE Record widest measured at ant./post. IHF, lat. Post. Parietal SAS at centrum semiovale [4]

Normal = <4 mm

Mild-moderate enlargement = 4-6 mm

Marked enlargement = >6 mm

WHITE MATTER MATURATION [1, 5]

For each hemisphere, mark level of maturation noted on both T1 and T2

Stage	Myelination
W0	Immature (<30 week) myelination pattern - i.e. brain stem not myelinated, etc.
W1	brain stem, dorsal aspect of pons
W2	ventral pons, cerebellar medulla
W3	PLIC, lenticular nucleus, thalamus
W4	corona radiata
W5	corticospinal tracts of the precentral and postcentral gyri
NE	Not Evaluable

CORPUS CALLOSUM

Provide SAGITTAL measured width at each of the following

Genu

Body

Splenium

LATERAL VENTRICLE SIZE, ASYMMETRY AND DISPROPORTION [4, 6]

SIZE: Measure ventricular/brain index (V/B index) **ON AXIAL T1 or FLAIR IMAGES**. Enter measured V/B ratio for right and left sides

Frontal horn ABNORMAL = V/B ratio>0.35

Midbody ABNORMAL = V/B ratio>0.35

Trigone ABNORMAL = V/B ratio >0.60

ASYMMETRY:

Mark "yes" in appropriate box if one ventricle is clearly larger than the other

DISPROPORTION:

Record "yes" if clear disproportionate shape of lateral ventricle, including but not limited to "squared"

D. INTRAVENTRICULAR CONTENT

Describe presence or absence of choroid cyst and hemorrhage as indicated.

Describe presence or absence of intraventricular hemorrhage, shunt, and mineralization as indicated

E. OTHER

Record maximum transverse and vertical dimension of fourth ventricle and maximum transverse dimension of third ventricle in mm.

Subject: RE: SUPPORT neuroimaging secondary - cranial US

If I can get coverage for my clinical duties for 2 days, I could do May 10-11. I can also do June 28 and 29.

I assume this is for the FIRST of the 2 central readings. I am skeptical that we will have all (or nearly all) the CUS in to RTI even by June 28, but I know Rose and RTI can work miracles - so maybe I should be optimistic. I would think the 2nd and final central reading might be better scheduled for the summer? Like early August?

Susan

So here are the three possibilities for meetings. Which of these will work best for you all?

Sunday, May 10 - Monday May 11 in Washington, DC

Sunday, May 17 - Monday, May 18 in Washington, DC or Detroit

Sunday, June 28 - Monday, June 29 in Detroit

I think 2 days each time might work - it depends on how the images are transfered... are they still all on disc?

It would be great to start with a 2 day meeting and see how fast it goes - hopefully Tom would be up to coming to DC. the schedule is tight this spring for me.

I could get room for us at CNMC.

Let me know TOM if a trip to DC would work for you. Where in NC is your data base?

Hi Dorothy and Tom,

It has been about 2 years since we last spoke about the "way far away" end of the SUPPORT trial - and the beginning of the central reading of the CUS for the Neuroimaging and Neurodevelopmental Secondary of that trial. Well, the time has come! The last patient was enrolled last week, so we would like to start planning and thinking about the process of the central reading.

As I explained when we first communicated about this trial, we will have 2 CUS from each of the ~500-550 patients that are enrolled in the neuroimaging secondary and survive to 36 weeks (one at <14 days and one at ~36 weeks PMA). We will also have an MRI at ~36 weeks for each of these patients - Pat Barnes will be central reader for those. We now are very excited to have not only 18-22 month neurodevelopmental follow-up funded, but ALSO 6-7 year follow-up. This will really be a great opportunity for us to evaluate the predictive capabilities of early and late CUS, compare with MRI, the contribution of neuroimaging to outcomes prediction in general for extremely preterm infants, and importantly to assess differences in neuroimaging abnormalities with respect to randomized interventions of oxygen saturation targets and ventilation strategies. This will be the largest preterm cohort in the world with complete, centrally-read neuroimaging and neurodevelopmental follow-up, and the only one to date with exclusively extremely preterm infants (<28 weeks). We will also be the first

When we communicated previously, it sounded like you both were in favor of at least an attempt at an "omnibus" central reading rather than getting them sent to you individually in drips and drabs. I agree in principal that this is the best approach so we can have support and helpers from the data center to help fill in the forms while you read, making things move faster. However, with ~1100 CUS, I wonder if this could really be accomplished in one single central reading event. So, my questions to you are:

1) How long will this take?: Since you have both been involved in so many trials as central readers, you will of course have a better estimate than I for how long/ how many hours and days it will take to read this many CUS. Is it reasonable to plan for 2 x central reading "events" - perhaps 2-3 days each? Contrasting with the Premie iNO central reading - a) there were fewer cranial US for PiNO than we will have for SUPPORT, b) all the PiNO CUS were not able to be read during the one central reader event, thus you both had to finish up on your own (which was probably not so easy and made things go more slowly), but c) the severity of illness for the PiNO patients was MUCH greater than for the SUPPORT patients, and I would expect that the CUS will not be as complex to read as those.

2) Location: We could do the central reading in D.C. (as we did with PiNO, as long as Dorothy can get us the space), or in North Carolina where the data center is located, or in Detroit (as long as Tom can get us the space). If we have two central reading events, we could do one close to Dorothy and one close to Tom. In any case, the data center has committed to providing "helpers" no matter where the readings occur!

3) Deadlines: We do not have all the CUS at the data center yet - some of the patients have not even reached the 36 week mark - but we have many. Also, we would love to have the readings completed by early fall 2009 (September) in order to potentially make the late breaker deadline for PAS. So, we would like to plan for a first central reading event as soon as practicable for you both. Carolyn Petrie Huitema (who helped to organize the PiNO central reading) and Kris Zaterka from RTI have been cc'd on this email and they will be helping to schedule all of this with you both.

4) Contract issues: I am not in the loop about the contracting and remuneration side of this - but Dr. Abhik Das from RTI will be the initial point person for those discussions with you both. He is also cc'd on this email.

OK - that is it for now. We are truly excited about this trial, and about the information we can provide for care providers and families. I am also very excited to continue communications with you about ideas for other analyses for these neuroimaging data we can work on together - we have a very, very rich database for these patients, and this will be an exciting and unique opportunity to learn more!

Thanks,

Susan

I am ok with this time frame.

We need to start generating lists of missing CUS and MRI studies and I will remind the sites

Second reading may need to be a little later in order to insure having the bulk of the studies.

Rose

So it seems like we could go with May 10-11 in DC. Should I confirm this with the group?

A couple of questions:

She would we wait on setting up the 2nd weekend?
Kris is talking to Marie this morning to see when the last kid will reach 42 weeks to see if we will have all CUS returned to RTI by June.
If we do the second reading at the end of June, this will follow the NRN SC meeting, which means Kris and Susan will be in DC, so this may be a good option and a good reason to hold the second training in DC.

Thoughts?

Subject: SUPPORT neuroimaging secondary - cranial US
Hi Dorothy and Tom,

It has been about 2 years since we last spoke about the "way far away" end of the SUPPORT trial - and the beginning of the central reading of the CUS for the Neuroimaging and Neurodevelopmental Secondary of that trial. Well, the time has come! The last patient was enrolled last week, so we would like to start planning and thinking about the process of the central reading.

As I explained when we first communicated about this trial, we will have 2 CUS from each of the ~500-550 patients that are enrolled in the neuroimaging secondary and survive to 36 weeks (one at <14 days and one at ~36 weeks PMA). We will also have an MRI at ~36 weeks for each of these patients - Pat Barnes will be central reader for those. We now are very excited to have not only 18-22 month neurodevelopmental follow-up funded, but ALSO 6-7 year follow-up. This will really be a great opportunity for us to evaluate the predictive capabilities of early and late CUS, compare with MRI, the contribution of neuroimaging to outcomes prediction in general for extremely preterm infants, and importantly to assess differences in neuroimaging abnormalities with respect to randomized interventions of oxygen saturation targets and ventilation strategies. This will be the largest preterm cohort in the world with complete, centrally-read neuroimaging and neurodevelopmental follow-up, and the only one to date with exclusively extremely preterm infants (<28 weeks). We will also be the first

When we communicated previously, it sounded like you both were in favor of at least an attempt at an "omnibus" central reading rather than getting them sent to you individually in drips and drabs. I agree in principal that this is the best approach so we can have support and helpers from the data center to help fill in the forms while you read, making things move faster. However, with ~1100 CUS, I wonder if this could really be accomplished in one single central reading event. So, my questions to you are:

1) How long will this take?: Since you have both been involved in so many trials as central readers, you will of course have a better estimate than I for how long/ how many hours and days it will take to read this many CUS. Is it reasonable to plan for 2 x central reading "events" - perhaps 2-3 days each? Contrasting with the Premie iNO central reading - a) there were fewer cranial US for PiNO than we will have for SUPPORT, b) all the PiNO CUS were not able to be read during the one central reader event, thus you both had to finish up on your own (which was probably not so easy and made things go more slowly), but c) the severity of illness for the PiNO patients was MUCH greater than for the SUPPORT patients, and I would expect that the CUS will not be as complex to read as those.

2) Location: We could do the central reading in D.C. (as we did with PiNO, as long as Dorothy can get us the space), or in North Carolina where the data center is located, or in Detroit (as long as Tom can get us the space). If we have two central reading events, we could do one close to Dorothy and one close to Tom. In any case, the data center has committed to providing "helpers" no matter where the readings occur!

3) Deadlines: We do not have all the CUS at the data center yet - some of the patients have not even reached the 36 week mark - but we have many. Also, we would love to have the readings completed by early fall 2009 (September) in order to potentially make the late breaker deadline for PAS. So, we would like to plan for a first central reading event as soon as practicable for you both. Carolyn Petrie Huitema (who helped to organize the PiNO central reading) and Kris Zaterka from RTI have been cc'd on this email and they will be helping to schedule all of this with you both.

4) Contract issues: I am not in the loop about the contracting and remuneration side of this - but Dr. Abhik Das from RTI will be the initial point person for those discussions with you both. He is also cc'd on this email.

OK - that is it for now. We are truly excited about this trial, and about the information we can provide for care providers and families. I am also very excited to continue communications with you about ideas for other analyses for these neuroimaging data we can work on together - we have a very, very rich database for these patients, and this will be an exciting and unique opportunity to learn more!

Thanks,

So it seems like we could go with May 10-11 in DC. Should I confirm this with the group?

A couple of questions:

She would we wait on setting up the 2nd weekend?
Kris is talking to Marie this morning to see when the last kid will reach 42 weeks to see if we will have all CUS returned to RTI by June.
If we do the second reading at the end of June, this will follow the NRN SC meeting, which means Kris and Susan will be in DC, so this may be a good option and a good reason to hold the second training in DC.

Thoughts?

Hi all

I got a couple days of coverage for May 10-11 dates - so I could do that for sure -

Susan

the May dates are best for me

If I can get coverage for my clinical duties for 2 days, I could do May 10-11. I can also do June 28 and 29.

I assume this is for the FIRST of the 2 central readings. I am skeptical that we will have all (or nearly all) the CUS in to RTI even by June 28, but I know Rose and RTI can work miracles - so maybe I should be optimistic. I would think the 2nd and final central reading might be better scheduled for the summer? Like early August?

Subject: SUPPORT neuroimaging secondary - cranial US
Hi Dorothy and Tom,

It has been about 2 years since we last spoke about the "way far away" end of the SUPPORT trial - and the beginning of the central reading of the CUS for the Neuroimaging and Neurodevelopmental Secondary of that trial. Well, the time has come! The last patient was enrolled last week, so we would like to start planning and thinking about the process of the central reading.

As I explained when we first communicated about this trial, we will have 2 CUS from each of the ~500-550 patients that are enrolled in the neuroimaging secondary and survive to 36 weeks (one at <14 days and one at ~36 weeks PMA). We will also have an MRI at ~36 weeks for each of these patients - Pat Barnes will be central reader for those. We now are very excited to have not only 18-22 month neurodevelopmental follow-up funded, but ALSO 6-7 year follow-up. This will really be a great opportunity for us to evaluate the predictive capabilities of early and late CUS, compare with MRI, the contribution of neuroimaging to outcomes prediction in general for extremely preterm infants, and importantly to assess differences in neuroimaging abnormalities with respect to randomized interventions of oxygen saturation targets and ventilation strategies. This will be the largest preterm cohort in the world with complete, centrally-read neuroimaging and neurodevelopmental follow-up, and the only one to date with exclusively extremely preterm infants (<28 weeks). We will also be the first

When we communicated previously, it sounded like you both were in favor of at least an attempt at an "omnibus" central reading rather than getting them sent to you individually in drips and drabs. I agree in principal that this is the best approach so we can have support and helpers from the data center to help fill in the forms while you read, making things move faster. However, with ~1100 CUS, I wonder if this could really be accomplished in one single central reading event. So, my questions to you are:

1) How long will this take?: Since you have both been involved in so many trials as central readers, you will of course have a better estimate than I for how long/ how many hours and days it will take to read this many CUS. Is it reasonable to plan for 2 x central reading "events" - perhaps 2-3 days each? Contrasting with the Premie iNO central reading - a) there were fewer cranial US for PiNO than we will have for SUPPORT, b) all the PiNO CUS were not able to be read during the one central reader event, thus you both had to finish up on your own (which was probably not so easy and made things go more slowly), but c) the severity of illness for the PiNO patients was MUCH greater than for the SUPPORT patients, and I would expect that the CUS will not be as complex to read as those.

2) Location: We could do the central reading in D.C. (as we did with PiNO, as long as Dorothy can get us the space), or in North Carolina where the data center is located, or in Detroit (as long as Tom can get us the space). If we have two central reading events, we could do one close to Dorothy and one close to Tom. In any case, the data center has committed to providing "helpers" no matter where the readings occur!

3) Deadlines: We do not have all the CUS at the data center yet - some of the patients have not even reached the 36 week mark - but we have many. Also, we would love to have the readings completed by early fall 2009 (September) in order to potentially make the late breaker deadline for PAS. So, we would like to plan for a first central reading event as soon as practicable for you both. Carolyn Petrie Huitema (who helped to organize the PiNO central reading) and Kris Zaterka from RTI have been cc'd on this email and they will be helping to schedule all of this with you both.

4) Contract issues: I am not in the loop about the contracting and remuneration side of this - but Dr. Abhik Das from RTI will be the initial point person for those discussions with you both. He is also cc'd on this email.

OK - that is it for now. We are truly excited about this trial, and about the information we can provide for care providers and families. I am also very excited to continue communications with you about ideas for other analyses for these neuroimaging data we can work on together - we have a very, very rich database for these patients, and this will be an exciting and unique opportunity to learn more!

Thanks,

Susan

Hi all,

The concern I have about reading these HUS in Detroit is the logistics of moving the US around. It makes sense to me to read them all in DC because we can house all scans at RTIs DC or Rockville office (I can drive them up for the first reading and then they can read as many as possible and we can bring the rest back to RTI to be read another day). If we go to Detroit not only do we have to bring the US up there, we might have to bring some back un-read if there is not enough time. I just think it leaves a lot of room for images to get damaged or lost.

Currently per the data there are 484 complete cases (MRI plus both HUS). Right now I have 163 HUS on films and over 250 HUS on CD (the majority of the CDs are per case so they have both early and late on one CD) in my office. I will send out a reminder to the sites to send the images in asap.

Thanks,
Kris

Date:	Tuesday, March 03, 2009 5:33:18 PM
Attachments:	SUPPORTCoordinators_Updated20090303.DOC SUPPORT Oximeter by Center Home 20080131.pdf

Dear all,

Now that the Support trial has completed enrollment and as your remaining infants complete the study per protocol; please return the study Masimo oximeters to their original institutions (Oximeter owner in the attached pdf file). Please also find attached an updated address list (Support Coordinator file attached) to include addresses for Miami, Wake Forest, Rochester and UCSD. Please clean all equipment and include sensors and probes prior to sending them home. For those oximeters currently being repaired at Masimo, please send the original institution an email listing the serial number being repaired and send that oximeter on once received back from Masimo.

Thank you all very much,
Kris

Rose,

Congratulations! Yes, we would like to do that. Also, 2 pulse oximeters came back to us from Stanford today. Will each center that has our oximeters be sending them back to us individually? If so, please let them know that offices have moved.

It would be: Central Building, Suite 740, Jackson Memorial Hospital, 1611 NW 12 Avenue, Miami, FL 33136.

Thanks
Shahnaz

Subject: SUPPORT

Hi
We enrolled our last (#1310) infant into SUPPORT late last week. We are quite interested in getting results out once the final infant reaches status. For the growth secondary study, would you like us to set up a call so we can discuss the analysis and create tables for the paper?? Let me know

Thanks

Rose

Hello All-

Please provide your availability below so we can finalize dates for these meetings. The first meeting will be held in DC and the second will be held in either NC or Detroit. For the weeks listed below, please indicate which days you would not be available to meet.

Week of:

April 13th –

April 20th –

April 27th –

May 4th –

May 11th –

May 18th –

May 25th –

June 1st –

June 8th –

June 15th –

June 22nd –

June 29th –

Thanks,
Meg

Subject: RE: SUPPORT neuroimaging secondary - cranial US

I think 2 days each time might work - it depends on how the images are transfered... are they still all on disc?

It would be great to start with a 2 day meeting and see how fast it goes - hopefully Tom would be up to coming to DC. the schedule is tight this spring for me.

I could get room for us at CNMC.

Let me know TOM if a trip to DC would work for you. Where in NC is your data base?

Dorothy Bulas MD

Subject: SUPPORT neuroimaging secondary - cranial US
Hi Dorothy and Tom,

It has been about 2 years since we last spoke about the "way far away" end of the SUPPORT trial - and the beginning of the central reading of the CUS for the Neuroimaging and Neurodevelopmental Secondary of that trial. Well, the time has come! The last patient was enrolled last week, so we would like to start planning and thinking about the process of the central reading.

As I explained when we first communicated about this trial, we will have 2 CUS from each of the ~500-550 patients

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

that are enrolled in the neuroimaging secondary and survive to 36 weeks (one at <14 days and one at ~36 weeks PMA). We will also have an MRI at ~36 weeks for each of these patients - Pat Barnes will be central reader for those. We now are very excited to have not only 18-22 month neurodevelopmental follow-up funded, but ALSO 6-7 year follow-up. This will really be a great opportunity for us to evaluate the predictive capabilities of early and late CUS, compare with MRI, the contribution of neuroimaging to outcomes prediction in general for extremely preterm infants, and importantly to assess differences in neuroimaging abnormalities with respect to randomized interventions of oxygen saturation targets and ventilation strategies. This will be the largest preterm cohort in the world with complete, centrally-read neuroimaging and neurodevelopmental follow-up, and the only one to date with exclusively extremely preterm infants (<28 weeks). We will also be the first

When we communicated previously, it sounded like you both were in favor of at least an attempt at an "omnibus" central reading rather than getting them sent to you individually in drips and drabs. I agree in principal that this is the best approach so we can have support and helpers from the data center to help fill in the forms while you read, making things move faster. However, with ~1100 CUS, I wonder if this could really be accomplished in one single central reading event. So, my questions to you are:

1) How long will this take?: Since you have both been involved in so many trials as central readers, you will of course have a better estimate than I for how long/ how many hours and days it will take to read this many CUS. Is it reasonable to plan for 2 x central reading "events" - perhaps 2-3 days each? Contrasting with the Premie iNO central reading - a) there were fewer cranial US for PiNO than we will have for SUPPORT, b) all the PiNO CUS were not able to be read during the one central reader event, thus you both had to finish up on your own (which was probably not so easy and made things go more slowly), but c) the severity of illness for the PiNO patients was MUCH greater than for the SUPPORT patients, and I would expect that the CUS will not be as complex to read as those.

2) Location: We could do the central reading in D.C. (as we did with PiNO, as long as Dorothy can get us the space), or in North Carolina where the data center is located, or in Detroit (as long as Tom can get us the space). If we have two central reading events, we could do one close to Dorothy and one close to Tom. In any case, the data center has committed to providing "helpers" no matter where the readings occur!

3) Deadlines: We do not have all the CUS at the data center yet - some of the patients have not even reached the 36 week mark - but we have many. Also, we would love to have the readings completed by early fall 2009 (September) in order to potentially make the late breaker deadline for PAS. So, we would like to plan for a first central reading event as soon as practicable for you both. Carolyn Petrie Huitema (who helped to organize the PiNO central reading) and Kris Zaterka from RTI have been cc'd on this email and they will be helping to schedule all of this with you both.

4) Contract issues: I am not in the loop about the contracting and remuneration side of this - but Dr. Abhik Das from RTI will be the initial point person for those discussions with you both. He is also cc'd on this email.

OK - that is it for now. We are truly excited about this trial, and about the information we can provide for care providers and families. I am also very excited to continue communications with you about ideas for other analyses for these neuroimaging data we can work on together - we have a very, very rich database for these patients, and this will be an exciting and unique opportunity to learn more!

Thanks,

Susan

In preparation for finalizing SUPPORT Neuroimaging and Neurodevelopmental Outcomes Cohort 6-7 year extended follow-up assessment and questionnaire battery, we need your help in identifying the resources and experience currently available at your site.
Please answer the following questions, complete the tables, and return to **Jamie Newman (newman@rti.org) by MARCH 3rd.**

SUPPORT Child Assessments			
Assessment Name	**Currently administer in:**		**Do not currently administer, but have access to testing materials (Y/N)**
	English	**Spanish**	
1. WISC IV			Yes
2. WISC IV - Spanish Version			No
3. NEPSY II (2008 version)			No
4. Woodcock-Johnson III – ACH • Letter/Word Identification • Calculation			May have access
5. Woodcock-Johnson III – Spanish version **(Bateria III)** - ACH • Letter/Word Identification • Calculation			No

6. If your site administers any of the above assessments in Spanish, are they administered by a :

a. Spanish speaking examiner (Y/N)

b. English speaking examiner with Spanish interpreter (Y/N)

7. Does your site currently perform the complete Movement – ABC II exam (not the checklist)? Y/N

8. If your site does perform the full Movement-ABC II (not checklist), who performs it at your site (i.e., physical therapist, occupational therapist, physician examiner, etc.)? _____

Rose

Will this call just be on the HUS readings? Should we have another call with Dr Barnes about getting the MRI part - I.e. How many MRIs left (I think many many...), timeline for getting the studies read, timeline for data entry and analyses...

Thanks Rose. I am getting a bit stressed actually.

Title: The Process of Antenatal Consent in a Large Multicenter Trial -

Wade Rich BSHS,RRT,CCRC, Kathy Auten MSHS, Marie Gantz PhD, Ellen Hale RN,BS, Angelita Hensman RNC, Nancy Newman BA, RN, Nancy Peters RN CCRP, Neil Finer, MD for the NICHD Neonatal Research Network[1]Pediatrics/Neonatology, UCSD Medical Center, San Diego, CA, United States.

Background: Prospective research in infants involving randomization at the time of birth requires that informed consent be carried out in the antenatal period. Trial projections often fail to recognize that the number enrolled may be significantly less than those screened or consented.

Objective: This study was designed to quantify the time and effort involved in enrolling infants into the NICHD Neonatal Research Network SUPPORT trial and better predict the true cost of recruitment into a complex trial of continuous positive airway pressure vs. intubation and surfactant in the delivery room and randomization to 2 goal ranges of saturation in the NICU.

Design/Methods: A data form was designed to quantify eligible mothers at each center, determine who approached them, how often, the duration of contact and whether the infants were eventually enrolled.

Results: 2798 women were identified at 18 collaborating units as being at risk for premature delivery at 24 to 27 6/7 wks GA between October 2005 and February 2009. 2211 were approached for informed consent. Most frequent reasons for not approaching included the presence of fetal abnormalities, active labor and language barriers. A study coordinator/research RN made 75% of all first approaches. For 77% of those approached, consent was attempted < 2 times. (Range 1-11). GA at time of screening was not different for those who consented vs those who did not. 7% of those screened were identified as having been approached for another maternal study and 1% for another neonatal study. Of the 2211 approached for consent, 1209 gave consent, 575 subsequently delivered 652 infants within study window, and 607 infants from 532 mothers were enrolled. Only 19% of those screened delivered infants who subsequently enrolled in the study. There was a significant relationship between performing a neonatal consult and obtaining consent ($p<.0001$). Centers that are also NICHD Maternal Fetal Medicine network centers enrolled at a higher rate and were more likely to use $\leq$30 minutes to request consent.

Conclusions: In a complex interventional trial of preterm infants, nearly 5 women were identified as likely to deliver a baby in the window for every infant enrolled in the trial. Extrapolating these data to all 1310 infants enrolled in the SUPPORT trial suggest that > 6000 eligible women were screened. These data should assist in developing the true cost of trials requiring antenatal consent.

Background: Prospective research in infants involving randomization at the time of birth requires that informed consent be carried out in the antenatal period. Trial projections often fail to recognize that enrollment numbers may be significantly lower than screening and consent rates..

Objective: This study was designed to quantify the time and effort involved in enrolling infants into the NICHD Neonatal Research Network SUPPORT trial and better predict the true cost of recruitment into a complex trial of continuous positive airway pressure vs. intubation and surfactant in the delivery room and randomization to 2 goal ranges of saturation in the NICU.

Design/Methods: A data form was designed to quantify eligible mothers at each center, determine who approached them, how often, the duration of contact and whether the infants were eventually enrolled.

Results: 2798 women were identified at 18 collaborating units as being at risk for premature delivery at 24 to 27 6/7 wks GA between October 2005 and February 2009. 2211 were approached for informed consent. Most frequent reasons for not approaching included the presence of fetal abnormalities, active labor and language barriers. A study coordinator/research RN made 75% of all first approaches. For 77% of those approached, consent was attempted < 2 times. (Range 1-11). GA at time of screening was not different for those who consented vs those who did not. 7% of those screened were identified as having been approached for another maternal study and 1% for another neonatal study. Of the 2211 approached for consent, 1209 gave consent, 575 subsequently delivered 652 infants within study window, and 607 infants from 532 mothers were enrolled. Only 19% of those screened delivered infants who subsequently enrolled in the study. There was a significant relationship between performing a neonatal consult and obtaining consent ($p<.0001$). Centers that are also NICHD Maternal Fetal Medicine network centers enrolled at a higher rate and were more likely to use <30 minutes or less to request consent.

Conclusions: In a complex interventional trial of preterm infants, nearly 5 women were identified as likely to deliver a baby in the window for every infant enrolled in the trial. Extrapolating these data to all 1310 infants enrolled in the SUPPORT trial suggest that > 6000 eligible women were screened. These data should assist in developing the true cost of trials requiring antenatal consent.

Hi Brenda,

If the infants were in room air on the day they were supposed to be tested then that's reflected on both the NG07 (question c.1.f answered 6=Weaned to room air on/before day of evaluation) and on the PHY01 (question b.8 answered 6=Weaned to room air on/before day of evaluation). Is that what you were talking about?

Thanks for your help on this!

Marie,
That is my error they are in for GDB not PHY01. I will take care of it later today. I think, but will need to check that both were actually in room air when I went to test them. I don't remember the form by heart but I think I explain that in a comment via F5?

Subject: RE: SUPPORT

Hi Brenda,

Just to clarify, you're saying that there are PHY01 forms entered for these two infants? Jenny checked on the PHY data from Tufts (last data received on the 17th) and these two infants were not in the files, so maybe they just need to be retransmitted? As a reminder, although the physiologic definition forms are no longer transmitted to RTI for GDB infants, they are still sent for SUPPORT infants, per technical memo PHY5, attached. The two infants in question were on room air by NC at 36 weeks according to the NG07, thus the PHY01 is expected.

Thanks, and let me know if there is anything else I can do to help.

Physiologic Definition of Bronchopulmonary Dysplasia
Physiologic Definition of BPD **Technical Memo # 5 (PHY5)**
Generic Database **Technical Memo #22 (GDB22)**
SUPPORT **Technical Memo #14 (SUP14)**
EOS **Technical Memo #07 (EOS07)**

TO: Network Coordinators
Network PIs

FROM: The Data Coordinating Center

SUBJECT: Physiologic Definition of Brochopulmonary Dysplasia Study

Physiologic Definition of BPD

The stand alone Physiologic Definition of Bronchopulmonary Dysplasia (BPD) study will become a subset of the GDB on May 1, 2008, per the decision of the Steering Committee at the January 2008 meeting. Data forms created for the Physiologic Definition of BPD (PHY01 and PHY02) will be used as worksheets for the revised NG07 and only entered into the data management system (DMS) when specified as necessary for individual studies.

Infants that are 36 wks PMA and eligible for challenge before May 1, 2008 should complete the current PHY01 and PHY02 forms and NG07 form version date (January 1, 2006. Infants 36 wks PMA and eligible for challenge after May 1, 2008 are no longer required to enter the PHY01 and PHY02 forms and should complete the NG07 form version date May 1, 2008.

The following questions have been added on the May 1, 2008 version of the GDB study Respiratory Support form (NG07) to document whether or not an infant has BPD using the physiologic definition of BPD.

1. Is the infant eligible for the physiologic evaluation? Y N
If YES to question C.1
a. Was the evaluation performed? Y N
If YES to question C.1.a
b. Date of evaluation __ __ / __ __ / __ __ __ __ (Month / Day / Year)
c. Actual FiO2 being delivered at time of challenge For infants receiving blended supplemental oxygen via nasal cannula, record the blend in this field. __ . __ __
d. If on nasal cannula at time of challenge, record flow rate __ . __ __ __ *LPM*
e. Did the patient pass the evaluation? Y N
If NO to question C.1.a
f. If patient was eligible and evaluation not done, code reason.

1= Increased FiO2
2= Increased respiratory support (cpap or vent)
3= Instability (including Surgery/Sepsis)
4 = Parent/Physician Refusal
6 = Weaned to room air on/before day of evaluation
9 = Other- explain

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

The physiologic evaluation for BPD will be completed on eligible SUPPORT study infants. The results of the evaluation will be recorded on the revised NG07. In addition to the NG07 data, the PHY01 and PHY02 forms will continue to be entered into the DMS for SUPPORT patients whenever section **C. Physiologic Evaluation** on the new NG07 is required to be completed.

EOS Study

Infants enrolled in the EOS study, outside of the GDB criteria will NOT have the physiologic definition of BPD performed for the purposes of the EOS study. Infants outside of the GDB criteria (a gestational age greater than or equal to 29 week and weighing 1001-1500g) will continue to have other relevant GDB data collected.

Title: The Process of Antenatal Consent in a Large Multicenter Trial -

Wade Rich BSHS,RRT,CCRC, Kathy Auten MSHS, Marie Gantz PhD, Ellen Hale RN,BS, Angelita Hensman RNC, Nancy Newman RNC, Nancy Peters RN CCRP, Neil Finer, MD for the NICHD Neonatal Research Network[1]Pediatrics/Neonatology, UCSD Medical Center, San Diego, CA, United States.

Background: R~~**Prospective** r~~esearch in newborn infants that involves randomization at the time of birth usually~~,~~ requires that the process of informed consent be carried out in the antenatal period. (All RCTs are prospective but some may not require consent)

Objective: This study was designed to quantify the time and effort involved in enrolling infants into the recently completed NICHD Neonatal Research Network SUPPORT trial, a complex 2x2 factorial randomized controlled trial of continuous positive airway pressure vs. intubation and surfactant in the delivery room and randomization to two levels of oxygen exposure.

Design/Methods: A data collection form was designed to quantify the true numbers of eligible mothers at each center~~,~~ ~~—~~and to determine who approached them, how often,~~ for~~ how long, and whether the infants were eventually enrolled.

Results: 2850 women were identified as being eligible in the 17 collaborating units as being at risk to deliver in the study window between October 2005 and February 2009, of whom 2300 were approached for informed consent. Most frequent reasons for not approaching included fetal abnormalities and active labor and language. Three fourths of first attempts were made by a study coordinator/research RN. 77% of mothers were approached 2 or fewer times~~.~~ (Range 1-11). Screening was evenly distributed over gestational window. GA at time of screening was not different for those who consented vs those who did not. Only 5% of screened subjects were identified as being in another maternal study~~,~~ ~~—~~and 8% in a neonatal study. Of the 2300 women approached for consent, 1225 provided consent, 1000 subsequently delivered in the study window and 610 infants were enrolled. Thus the enrollment rate was 21% of eligible women. There was a significant relationship between performing a neonatal consult and obtaining consent ($p<.02$). Centers who are also MFM centers (criteria for being an MFM center) approach more women, get more consults, enroll at a higher rate, and are more likely to use < 30 minutes.

Conclusions: In a complex interventional trial of sick preterm infants, five women were identified as likely to deliver a baby in the window for every infant enrolled in the trial. Extrapolating these~~is~~ data to the entire 1310 infants enrolled in the SUPPORT trial would suggest that over 6100 eligible women were screened. These~~his~~ data should assist in developing the true effort and cost of ~~trials requiring~~ antenatal consent for such trials.

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

Of the 2300 women approached for consent, 1225 provided consent, 1000 subsequently delivered in the study window and 610 infants were enrolled. Thus the enrollment rate was 21% of eligible women. There was a significant relationship between performing a neonatal consult and obtaining consent ($p<.02$). Centers who are also MFM centers approach more women, get more consults, enroll at a higher rate, and are more likely to use < 30 minutes.

Conclusions: In a complex interventional trial of sick preterm infants, five women were identified as likely to deliver a baby in the window for every infant enrolled in the trial. Extrapolating this data to the entire 1310 infants enrolled in the SUPPORT trial would suggest that over 6100 eligible women were screened. This data should assist in developing the true cost of trials requiring antenatal consent.

Title: The Process of Antenatal Consent in a Large Multicenter Trial -

Wade Rich BSHS,RRT,CCRC, Kathy Auten MSHS, Marie Gantz PhD, Ellen Hale RN,BS, Angelita Hensman RNC, Nancy Newman RNC, Nancy Peters RN CCRP, Neil Finer, MD for the NICHD Neonatal Research Network[1]Pediatrics/Neonatology, UCSD Medical Center, San Diego, CA, United States.

Background: Prospective research in newborn infants that involves randomization at the time of birth requires that the process of informed consent be carried out in the antenatal period.

Objective: This study was designed to quantify the time and effort involved in enrolling infants into the NICHD Neonatal Research Network SUPPORT trial, a complex 2x2 factorial randomized controlled trial of continuous positive airway pressure vs. intubation and surfactant in the delivery room and randomization to two levels of oxygen exposure.

Design/Methods: A data collection form was designed to quantify the true number of eligible mothers at each center and to determine who approached them, how often, for how long and whether the infants were eventually enrolled.

Results: 2798 women were identified at the 18 collaborating units as being at risk to deliver in the study window between October 2005 and February 2009, of whom 2211 were approached for informed consent. Most frequent reasons for not approaching included fetal abnormalities, active labor and translation issues. . Three fourths of attempts to obtain consent were made by a study coordinator/research RN. For 77% of mothers approached, consent was attempted 2 or fewer times. (Range 1-11). GA at time of screening was not different for those who consented vs those who did not. Only 7% of screened subjects were identified as being approached for another maternal study, and 1% were approached for another neonatal study. Of the 2211 women approached for consent, 1209 provided consent, 575 subsequently delivered 652 infants in the study window and 607 infants from 532 mothers were enrolled. Thus, only 19% of women who were screened delivered infants who were enrolled in the study. There was a significant relationship between performing a neonatal consult and obtaining consent ($p<.0001$). Centers that are also MFM centers enroll at a higher rate, and are more likely to use < 30 minutes.

Conclusions: In a complex interventional trial of sick preterm infants, nearly five women were identified as likely to deliver a baby in the window for every infant enrolled in the trial. Extrapolating this data to the entire 1310 infants enrolled in the SUPPORT trial would suggest that over 6000 eligible women were screened. These data should assist in developing the true cost of trials requiring antenatal consent.

Hi Wade,

I'll look into your question. Are we on for the abstract? If so, would you send me either a list of the tables you want me to rerun, or even better, copies of the old tables you want me to reproduce? FYI, we're only 10 infants away from completing SUPPORT enrollment (we're at 1300).

Thanks!

Subject: RE: Antenatal Consent

Hi Marie,
One of the things that stands out to me if the fact that we did not approach infants until they were 24+ wks. Almost no one approached 23 week moms. Would we be able to look at the number of infants who were born at 24wks (by day) compared to the number that were approached? I think it may be an important piece of information for trials of this type if we are missing the youngest kids. It would certainly be a strong argument for waiver of consent.

Subject: RE: Antenatal Consent

Hi Wade,

Attached are two documents. One contains the first and last birth dates and record creation dates for each center from the ANT01. In some cases, there is quite a bit of difference between the birth dates and record dates, but I looked at the data and they all appear to be legitimate. It looks like some centers just didn't have the chance to enter data in the DMS until well after data collection began.

The other document contains cross-tabulations of performing a consult vs. obtaining consent. Chi-square tests are given for each cross-tab.
The chi-square test is a test of independence, so if the p-value is significant it indicates that the consult and consent are not independent of one another. I have added some notes and (fairly hideous) color-coding to help you interpret the document. Let me know if you have any questions. I included tests for all centers together, all centers excluding those where a consult is always performed, and each center individually. By the way, if you are viewing the document on your computer screen, make sure that your page headers are visible. That's where the titles are (so you can tell which center(s) you're looking at).

Have a great weekend!

First and last birth date and first and last record creation date would be awesome.
There is also a statistic that Neil mentioned that I think would be helpful. I am not sure how to run it, but I would like to know the effect of performing an antenatal consult on obtaining a consent. It would be interesting to look at it by center, to see if the practice of doing consults effects
consent rates. Much to my surprise, only 2/3rd of the
Ante02s indicate a consult for a group of babies most of whom are being
seen at 24-26 weeks.

I think that should be the statisticians' motto! Yes, everything ends up being more complicated than you ever expected. Oh well, it keeps us busy.

Let's see... the only dates on the forms are the last date eligible for the moms and the birthdates for the infants. We also have the record creation dates for the entries. The record creation dates would reflect the start dates for the

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

centers, but also depend on how quickly the centers enter the data after it's collected. I can give you the first and last birth date, first and last record creation date, or both for each center. Does that help? I know from past experience that going this route is easier and more accurate than trying to look at something like IRB approval dates. What do you think?

Hi Marie,
Would it be possible to get Antenatal Consent start-months for all the centers? We (UCSD) are about 18 months out, but we started earlier than most. And I obviously need to account for the 4 centers who are out in 4/06, and how many months the 4 new ones have been
enrolling.
It all seems so easy when you start...
Wade

Hi Wade,

Unfortunately, there is no ID to link the records from SUPPORT to the Antenatal consent data (SUPPORT uses the usual network ID, but Antenatal consent has a separate "screening ID"). I think the best I could do is to look at the number of infants (and number of moms) enrolled at each center since they started participating in the Antenatal consent secondary.

I am a research nurse that works with Monica. She is away this week. The infant with GDB (b) (6) has not met the criteria for final acute status (not yet mature or in zone 3 for 2 exams). The infant had one exam on DOL 46 that showed immature vessels in zone 2 ou. The second exam showed immature vessels zone 3ou. The infant is beyond 55 weeks PMA and is to be scheduled for an exam sometime between May and September. We were waiting for the results of this exam to determine status. Let us know what you would like us to do.
Thank You,
JoAnn Poulsen

To: Higgins, Rosemary (NIH/NICHD) [E]
Subject: FW: Antenatal Consent
Date: Friday, February 13, 2009 1:49:59 PM

Hi Rose,

Neil asked if I would do a late-breaker abstract for the Antenatal Consent study, since it is not a secondary of SUPPORT as such. From whom do I need to get permission if such can be granted?

PS. Marie is up for it since she has already made the tables and just needs to re-run them.

Wade

To: Gantz, Marie
Subject: RE: Antenatal Consent

For an abstract I think what we did before is plenty. So it should just be rerunning them. It would be awesome to wait until the final kid is enrolled, but that may be too much to ask. In any case we will have 2800 eligibles.

Wade

To: Zaterka-Baxter, Kristin; Higgins, Rosemary (NIH/NICHD) [E]; Das, Abhik; Rich, Wade; Gantz, Marie
Subject: RE: question re: SUPPORT
Date: Friday, February 06, 2009 12:43:16 PM

Hi Kris

I think that the approach that the centers are taking is quite appropriate – I would continue to consent and indicate that if the study closes before their delivery, their child will not be enrolled. If we enroll 2-5 extra infants, that is not a problem, but because the SUPPORT consent is such a good tocolytic, I would keep trying to get consent. If we have some consented Moms that do not deliver but we are counting on that delivery to help enrollment, we will probably be waiting a while.

Thanks for everyone's great continuing efforts

Neil

Subject: FW: question re: SUPPORT

Hi,

Please see the email string below about consenting mom's in support given we are close to accrual goal; please comment on the centers' approaches if needed. I'm not sure we've had a discussion on a uniformed approach (or if it is needed).

Thanks and please note I've attached the original email to the string below; it was not included with the center responses.

Our plan here at Emory is to let moms know that if they consent and we reach our enrollment goal prior to their delivery they will not be enrolled. Our consent states that our enrollment goal is around 1300. We will inform moms that we are close to the goal now.

To all:

While consenting prenatally for SUPPORT, should we be telling the participants that its possible that they consent and deliver but wouldn't get enrolled?

For example: we consent MS Jones 2/3 she is 24 weeks , on 2/6 we reach 1310-- Ms Jones delivers the next day(2/7) still in the window, but would not get enrolled. Should we be letting the particpates know this during the consenting process?

Thanks, just wondered what everyone was doing for this

Rose, I think that this is a very worthwhile project but because it comes from our center I am a little biased and thus did not reply. We have started looking at the issue of sleep apnea in our current 6 year ELBW cohort of which I am a co PI with our neuropsychologist Dr Taylor who is PI. It is not clear to me whether the whole Support cohort is also funded for a pulmonary school age follow and how this is going to be coordinated with the neuroimaging cohort. It has become difficult to follow kids at school age in general as most mothers work now days and to have the families come in twice, once for the neruoimaging study and once for the pulmonary study is going to be difficult, Maureen

Subject: RE: Support request to sites for info
Date: Monday, February 02, 2009 4:22:41 PM

Hi all,

Rose recently got input from another psychologist at NICHD, and I think her response leaves the question still open about whether a Spanish-speaking examiner is REALLY needed for these tests -

Rose - am I interpreting your emails correctly on this point? Obviously, it will be best to have Spanish speaking psychologist examiners, and I think that should be the primary option we want to recommend to the sites. There is a good deal of lead time for the sites to set it up. But, if we can give the option to use a medical interpreter with a script it may mean better follow-up rates at some sites. Rose, let us know if this is the conclusion from your discussions with Lisa Freund.

As for parent questionnaires - I think that an interpreter is perfectly fine. All the "standardized" questionnaires we have chosen come in Spanish (because we pretty much decided that was a non-starter if they didn't).

Jamie and Jane - I will send a follow-on email re: suggestions to the questions/check list that Jane drafted.

Thanks

Susan

> Thanks for working on this, Jane. We're finding that the Centers doing the Hypothermia 6-7 year do not have a Spanish-speaking examiner on hand to perform the WISC-IV (they'll need to find a Spanish-speaking examiner in the community and pay them to do the WISC-IV). I am not clear on which of these measures can be administered by an interpreter and which ones will need to be administered by a Spanish-speaking examiner so that information may be helpful to add to the table. We're lucky to have the experience of Hypo Ext Follow-up so that we can think through and plan for the language issue in advance.

Here is my first attempt at this...see what you think. And here's my logic behind the grid. For assessments it is going to be important to know if they have the test kits because those are expensive. For the questionnaires I assumed that we would be buying those so the cost is not the issue and having access to them doesn't really matter even if they don't currently administer them.

Hmmmmm.....just thought of another question we might add. Should we ask if sites have a Spanish speaking individual who could a) administer some or all assessments or b) only administer questionnaires ? Not sure how to word that the most efficient way. To me "assessments" would refer to NEPSY or WISC and assumes some psych administration training. Questionnaires can be done by lots of people.

But - maybe you see the logic differently. Please weigh in. The goal is to make sure we only ask once (it at all possible) so I'm certainly open to making changes - this is just first draft.

Jane
P.S. - if we have a bunch of kids and parents who only speak Spanish, how are the docs/nurses dealing with this when kids come in for FU visits ?

Subject: Re: New SUPPORT infant--2nd Adverse Event

Rose,
They just finished up rounds on this infant. Regarding your question about the first tube possibly not draining--it was bubbling but Dr. Rosenfeld did feel it was not adequately working. When the 2nd chest tube was placed the infant responded very quickly--FiO2 decreased and blood pressure MAP quickly increased. Ultimately, they felt the air had reacumulated, and the 2nd chest tube resolved it.

So, would this be a second adverse event or an addition to the first event?
Kris??

Thanks

Subject: SUPPORT query
Date: Friday, January 30, 2009 4:04:37 PM

Hi,
I am following up on the following conflicting data:

12 (b) (6) FU marked as complete (per NF10/SF10) but NF05 and NF09a have not been completed

The NF05 has since been marked complete. Also, the NF10 was accidentally keyed as 1 for Q.A.2 – since the form was marked complete, I was unable to remove the 1 and save the form as incomplete. Therefore we have temporarily marked "6 – child seen, but incomplete visit" temporarily until the Bayley III is completed on the appt scheduled for (b) (6) I will at that time change the data back and key the NF11 and NF09A, as well.

Thanks so much!

To: Rosemary (NIH/NICHD) [E] Higgins; Zaterka-Baxter, Kristin; Nancy Miller; Pablo Sanchez
Subject: Adverse Event regarding new SUPPORT infant

Kris,
We had a new SUPPORT infant deliver on (b) (6). She was (b) (6) weeks and randomized to early intubation and surfactant. She received surfactant within the first hour of life and then a second dose at eight hours of life.
At 12-14 hours of life she developed (b) (6) and (b) (6).
Nancy is aware of this infant and you will be receiving the paperwork soon. She does not even have a network number yet.

Please let us know if there is anything else you need immediately.

Thanks

HI all,,,

I'll check w/ Danny about full protocol as he's study PI, here's the synopsis from the study abstract included in the protocol document.

it's a pK trial enrolling 200 kids to get meropenem at different doses/schedules depending on gestational and postnatal chronologic age. endpoints are primarily pK and safety.

Hello Everyone
We have not discussed this. The meropenum study is for pharmacokinetics and
it has usually been decided that the infant will get meropenum apart from
the research study. There is no placebo arm for this study. The only potential conflict could be blood draws - SUPPORT doesn't require any. I do
not believe that there is any conflict with SUPPORT.
The answer to your question from my perspective is YES.

PROTOCOL SYNOPSIS

Protocol Title	Multiple Dose Pharmacokinetic Study of Meropenem in Young Infants (<91 days) with Suspected or Complicated Intra-abdominal Infections
Sponsor:	NICHD
Product	Meropenem
Objectives:	a. To characterize meropenem single-dose and multiple-dose PK in subjects with suspected or complicated intra-abdominal infections. b. To characterize the safety profile of meropenem in the treatment of suspected or complicated intra-abdominal infections. c. To assess collected efficacy data for meropenem for the treatment of suspected or complicated intra-abdominal infections.
Study Design:	Multi-center, prospective, pharmacokinetic and safety study of meropenem for the treatment of suspected or complicated intra-abdominal infections
Study Population:	Premature and term young infants (<91 days) who have a suspected or early complicated intra-abdominal infection. These subjects must be subdivided into the following four groups: Group 1: GA at birth below 32 weeks - PNA < 2 weeks; Group 2: GA at birth below 32 weeks - PNA ≥ 2 weeks and < 91 days; Group 3: GA at birth 32 weeks or older - PNA < 2 weeks; Group 4: GA at birth 32 weeks or older - PNA ≥ 2 weeks and < 91 days.
Number of Infants:	Approximately 200 infants that complete the study
Number of Sites:	Approximately 25
Treatment:	Meropenem Aminoglycoside should be administered in conjunction with meropenem. Additional antimicrobial coverage may be added per standard of care.
Treatment Duration	At least 3 days; otherwise, per local standard of care (maximum 21 days)
PK/PD:	Minimal sampling and population PK will be employed
Safety:	The protocol will rely on three mechanisms for safety: 1) The DSMB 2) Adverse event and SAE reporting mechanisms 3) The active, daily, real time oversight of the MPODS Clinical Safety Committee All serious adverse events (SAEs) will be closely monitored throughout the course of the study. Seizures will be intensely monitored and clinical laboratories of renal, and hepatic toxicity monitored weekly as available per local standard of care. Safety assessments will include seizure documentation (including correlation of serum meropenem level and seizures), physical examination, clinical laboratory values, LFTs, renal function and nosocomial infections (tracked by pathogen).
Statistical Consideration:	The sample size is designed to assess single and multiple dose PK of meropenem in young infants. All infants who receive meropenem will be analyzed. These infants will comprise the population for the safety analysis, and if any PK samples are obtained, their blood will be evaluated in the PK analysis. Those infants who have an efficacy measurement at Day 28 will also be evaluated for clinical (efficacy) response. Key safety endpoints that will be evaluated in the final analysis: include death, seizures, strictures, perforation, wound dehiscence, short gut, development of extended beta lactamase infection, development of candidiasis, and antimicrobial therapy failure. The proportion of infants affected and 95% CI for each key safety endpoint will be reported. The following PK parameters will be estimated: a) Plasma clearance b) Volume of distribution c) Cmax, Tmax, AUC_{0-T}, (at steady state), Ke and $t_{1/2}$ $AUC_{0-\infty}$ (estimated from the 1st dose)
Inclusion Criteria	a. Written permission from parent or legal guardian b. Age younger than 91 days

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

	c. Likely to survive beyond the first 48 hours after enrollment d. Sufficient intravascular access (either peripheral or central) to receive study drug AND ONE OF THE FOLLOWING e. 1) Physical, radiological, and/or bacteriological findings of a complicated intra-abdominal infection. These include peritonitis, NEC Grade II or higher by Bell's criteria, Hirschsprung's disease with perforation, spontaneous perforation, meconium ileus with perforation, bowel obstruction with perforation, as evidenced by free peritoneal air on abdominal radiograph, intestinal pneumotosis or portal venous gas on abdominal radiographic examination. OR 2) Possible NEC OR 3) Otherwise receiving meropenem per local standard of care
Exclusion Criteria	a. Renal dysfunction evidenced by urine output <0.5 mL/hr/kg over the prior 24 hours b. Serum creatinine >1.7 mg/dL c. History of clinical seizures or EEG confirmed seizures d. Concomitant treatment with another carbapenem (ertapenem or imipenem) at the time of informed consent e. Any condition which would make the subject or the caregiver, in the opinion of the investigator, unsuitable for the study

Hello Everyone
We have not discussed this. The meropenum study is for pharmacokinetics and it has usually been decided that the infant will get meropenum apart from the research study. There is no placebo arm for this study. The only potential conflict could be blood draws – SUPPORT doesn't require any. I do not believe that there is any conflict with SUPPORT.
The answer to your question from my perspective is YES.

Neil

Hi,

I have been emailing Jenny about the coding for these babies and I hope we have these addressed.

Here are the situations for these babies.

(b) (6) did not have a second exam in Zone III as required for endpoint. The ophthomalogist wrote for 1 year follow up after this exam. This baby has been seen for the follow up visit and has vision.

(b) (6) has multiple health issues as well as a noncompliant mother. Mom had the eye exams very low on the priority list of appointments she did actually bring him to.

Thanks,

Cathy

Date: Saturday, January 24, 2009 5:49:50 AM

Ira and Rose,
Ira, You are correct. We should have a call for input. Rose, can we query all follow-up PIs regarding the Bayley III ?
Does your site administer only the cognitive and language composites at 18m ?
Does your site ever administer the total Bayley III ?
How long does it take ?
For this call we should also have the gold standards on the call.
The issue of high scores is another issue.
I was wondering if some of the sites that are doing the motor component could share those results.
We are doing the total Bayley III at 7 months and I know there are sites admininistering all at 18 months.

I am on my way to (b) (6) and will be out all day.
Hope we can discuss on Monday.
BV

Sent: Fri Jan 23 13:40:26 2009
Subject: Potential PAS Abstract
Hi Neil and Rose,

I have an idea, but I have been waiting for the SUPPORT data. Someone else may have already put in a request to do it. This is fine, I just want to be sure it is done, and I would be happy to help if there is already a leader.

The SUPPORT data will give us for the first time a solid dataset on what happens to ROP before vs after transfer or discharge. It will let us estimate the proportion of infants in major centers that really do have surprises after "status". Up to this point, neonatologists have almost always published 'what happened while they were in our hospital". This will let us estimate the error introduced by incomplete early follow up.

Neil, if someone is already planning this, just tell me to back off. (I have plenty to do with inositol).

Also, maybe 2010 may be too early since you'll be dealing with the primary outcomes and will not want to muck with this right away.

Your advice?

Dale

Subject: Support randomization question

I am in discussion with the parents of a set of quads about support enrollment. There is a possibility of "interval delivery" of quad A, who has ruptured membranes. Should this occur we will know some time prior to delivery which group the others will be randomized to. While the interval will likely be short, it could be prolonged to days or more. Any issues with this?

Subject: support secondary concept

Hi Neil...

you probably know (or maybe not) that I submitted a concept protocol
that
is really a secondary to SUPPORT entitled :Do Genetic Variations
Influence
ROP risk at High vs. Low Oxygen Saturation Target Range? The protocol
would
ask for DNA samples (oral swabs) from infants enrolled in SUPPORT who
are
returning either for 18 - 22 month followup or the later followup
involved
w/ neuroimaging. We would target looks at pathways to identify groups of

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

candidate genes from VEGF, HIF1alpha, and angiogenesis pathways....and use
tagSNP's to try to ID regions of genes in those pathways that are associated w/ ROP risk. The concept was approved 17 - 1, so we're working
on a full protocol to come back quickly for protocol committee review.....

I apologize for not talking much about this prior to submission of the concept...but I"m never sure about asking for anyone's time before it looks
like it's going anywhere. I don't think the DNA will affect participation
in the main trial the way we are approahing only on followup. I think there's a unique opportunity because of the detailed characterization of rop phenotype and the oxygen exposure data. Also,,,Lex Doyle mentioned that
he would be interested in sending a secondary to BOOST II committee leadership to collect DNA, independent of the Network's decision.

So...for this email, I'm sending the power point we presented last week....as the protocol develops if I may I"ll send it on.

thanks

mc

---

Dear Steering Committee and Follow-up PIs,

The SUPPORT Subcommittee has approved the Object Permanence Ancillary to the neuroimaging cohort, which involves one new form. The protocol and short data collection form are attached.

Please note that the protocol is titled "ANCILLARY STUDY TO SUPPORT FOLLOW UP: Evaluation of early working memory in extremely preterm infants" though it is being referred to it as the "Object Permanence Ancillary."

Thanks, Jamie

REVISED PROPOSAL FOR ANCILLARY STUDY TO SUPPORT FOLLOW UP:

Evaluation of early working memory in extremely preterm infants (10-29-08)

Protocol development group:

Jean Lowe Ph.D., Janell Fuller, MD, Kristi Watterberg, MD (UNM)

Susan Hintz, MD (Stanford)

Abstract: We propose to study early working memory in extremely preterm infants enrolled in the NICHD SUPPORT trial by recording and analyzing responses to 3 specific items from the Bayley Scales of Infant Development-III (Bayley-III) which measure object permanence (items 40, 45 and 50), and evaluating the relationship of "mastery of object permanence" to (1) performance on the Bayley-III at 18 – 22 months, (2) to MRI findings at term gestation, and (3) to performance on tests of executive function at 6 – 7 years of age.

Hypotheses:

1. Randomization to higher vs. lower oxygen saturation target ranges in the SUPPORT study will not affect the attainment of object permanence as assessed by the Bayley-III test of Cognition and Language at 18-22 months.
2. Among all children born extremely preterm (<28 0/7 weeks gestation), those who achieve object permanence mastery will do significantly better on the Bayley-III test of Cognition and Language at 18-22 months than those who do not.

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

3. Among all infants born extremely preterm, object permanence mastery at 18 months will not be affected by SES or ethnic grouping, in contrast to Bayley III Cognitive and Language scores.
4. Among those children born extremely preterm who had MRI scans at term, those who achieve object permanence mastery will have significantly fewer abnormal findings on the MRI performed at term as part of the SUPPORT trial.
5. Among those children born extremely preterm who had MRI scans at term, those who achieve object permanence mastery will perform significantly better on tests of executive function at 6 and 7 years.

Background and significance:

Executive function is an umbrella term that encompasses three main areas: working memory, inhibition, and cognitive flexibility (Davidson 2005). Recently we have seen more studies that look at working memory as a measure of executive functioning in school age outcome studies (Anderson 2004, Curtis 2002, Luciana 1999) with significant differences found between executive functioning in those children born preterm in comparison to children born at term. Studies have shown executive function deficits in children school-aged and older who were born prematurely (Anderson 2004), which persist even after taking IQ differences into account (Bayless 2007).

In one of the few studies of executive function with young children born preterm Woodward et al (2005) found that 2 year olds born preterm had difficulty encoding new information in working memory compared to term infants, and that on MRI children born preterm had bilateral reduction in cerebral tissue volume in areas specifically related to working memory (dorsolateral prefrontal cortex, parieto-occipital and premotor areas).

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

Studying these vulnerable populations at younger ages could result in executive function interventions that could be clinically useful. New measures have recently been developed which allow researchers to tap into the foundations of executive function in very young children, particularly their working memory, impulse control, and rule use (Carlson 2005). Although these new measures for preschool children have been employed with typically developing populations (Carlson 2005), there are currently very few studies investigating executive function in preschool children born prematurely. The few studies that have been conducted found that preschoolers born VLBW without major neurological deficits may have specific difficulty in sustained attention, visuospatial processing, and spatial working memory when compared with full term children matched for chronological age and IQ (Vicari 2004).

A recent randomized trial of early hydrocortisone treatment (Watterberg 2007) found that fewer hydrocortisone-treated patients had a Bayley-II MDI of <70 and that more of the hydrocortisone-treated children showed evidence of awareness of object permanence on the Bayley-II. Further investigation indicated that MDI scores were significantly higher in the white ethnic group while object permanence mastery was relatively similar across all ethnic groups (Blacks, Hispanics, Asians, whites) (Lowe, in press).

Our finding that object permanence mastery is not affected by either ethnic group or income could significantly improve our ability to identify children who are at-risk for later developmental sequelae, as the Bayley MDI – which is affected by those factors – is a poor predictor of later cognitive function (Hack 2005). Object permanence items as a measure of early working memory (Diamond 1997) have been related to the development

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

of prefrontal cortical function (Woodward 2005) and the earliest measure of reasoning skills in toddlers. This is relevant to intervention techniques that can be developed to specifically work on tasks that could enhance these skills. In conjunction with the Bayley Scales cognitive score, use of a measure of object permanence may also improve our detection of ongoing problems with executive function at 18-22 months, which is highly related to later learning difficulties. We therefore speculate that measurement of object permanence at 18 – 22 months will be a useful predictor of executive function at 6 – 7 years of age, and therefore may improve our ability to provide early intervention services to this population.

Methods:

We propose to prospectively record pass/fail for items 40, 45 and 50 from the Bayley-III Cognitive Scale in infants enrolled in the SUPPORT trial when they are evaluated at 18 – 22 months adjusted age. These object permanence items sequentially increase in difficulty. First, the child is asked to find a toy hidden under one of two cups (item 40). Second, the cups are reversed after the toy is hidden (item 45). Third, double visual displacement is used: the toy is hidden under one cup, removed and hidden a second time under the second cup (item 50). The number of object permanence items correctly completed is calculated for each child and used as an ordinal measure.

Because the SUPPORT study interventions are randomized, the analysis of the relationship of attainment of object permanence to the measures outlined in the hypotheses above should not be confounded by those interventions. We will test the null hypothesis that randomization to high vs. low saturation targets on "mastery of object

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

permanence" (**hypothesis #1).** We will then analyze (1) the relationship of 'mastery of object permanence', defined as achievement of two of these items, to performance on the Bayley-III Cognitive scale (**hypothesis #2)**; (2) the effect of SES and ethnic grouping on performance in both the cognitive scale and object permanence achievement **(hypothesis #3)**; (3) the relationship of mastery of object permanence to MRI findings at term gestation in those infants enrolled in the Neuroimaging secondary of the SUPPORT trial, specifically the number and/or size of lesions in the prefrontal, parieto-occipital and premotor areas (**hypothesis #4)**; and (4) the relationship of mastery of object permanence to achievement on tests of executive function (the NEPSY) at 6 and 7 years already included within the long-term follow up study of infants enrolled in the Neuroimaging secondary study of the SUPPORT trial (**hypothesis #5)**.

Power analysis: We anticipate that the smallest sample size for the above analyses will be for #5, outcomes at 6 – 7 years. Therefore, for a meaningful power analysis, we considered the post hoc comparison of mean IQ at age 6 – 7 years to attainment of object permanence (a score of 0 or 1 vs. 2 or 3), anticipating a one standard deviation IQ difference (e.g., 70 vs. 85). A sample size of 17 per object permanence score is adequate to detect such a difference with 80% power and alpha = .05. Our preliminary data (Watterberg 2007) indicates that 1/6 of our subjects had object permanence scores of 0, 1 or 2, and the remaining half had a score of 3 (Bayley II). The total sample size required at 6 - 7 year follow up would then be 17 x 6 = 102. This power analysis is also adequate for one standard deviation difference in other executive function measures at 6 – 7 years. We then assumed that the attrition rate for the 6 – 7 year follow

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

up could be as high as 50%, requiring at least 204 subjects evaluated at the 18 – 22 month visit.

Sample size/patient recruitment: We had initially planned to collect the object permanence items prospectively on patients enrolled in the neuroimaging ancillary study, since that sample size will be adequate to address all hypotheses. The SUPPORT neuroimaging cohort is estimated to include 400 – 450 survivors with complete MRI and ultrasound data. However, > 70 of the patients have already reached their second birthday, and the form changes may not be ready by January of 2009. Therefore, we propose enrolling all patients in the neuroimaging ancillary study by (1) prospectively collecting object permanence items at the time of the 18 – 22 month visit as soon as the form change can be instituted; and (2) retrieving these items for patients in the neuroimaging ancillary study who have already been seen, if the Bayley scoring sheet has been retained. This will help ensure an appropriate sample size for hypothesis #5 (correlation with 6 – 7 year follow up), regardless of attrition.

Budget: The components of the cost for this ancillary protocol include:

(1) Modification of Bayley data entry: this will require entering three specific items from the Bayley. Cost includes personnel time only.

   a. Per Conra Lacy (Coordinator, UNM), it should require less than 15 minutes/patient to enter these data prospectively. To complete as much of the cohort as possible, sites will be asked to retrieve these three items for those patients enrolled in the neuroimaging secondary only, if the raw data has been retained. Abstracting three items from these charts may add an additional 15 minutes/patient. Budget estimate: 450 patients @15mins

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

each = 112 hours of coordinator time. Adding 15 mins for each retrospectively obtained score (for a total of ½ hour for each of those patients), estimated at 100 patients x 15 mins = 25 hours of time, for a total of 137 hours @ $35/hour = $4795.

b. RTI programming: Per Dr. Das, "The re-programming needed for the Bayleys will require changes to the DMS form, report, end of record programming change, batch edit change, programming update to the existing Bayley data table on the Centers computers and adding the new fields to the conversion to SAS process. Since it's only 3 purportedly simple questions to an existing form, it wouldn't take as long as creating a new form or adding something with a complicated skip pattern affecting the rest of the form. I would guess around 12 hours of programming time total. Additional time would be added if any special reports needed to be created for tracking, etc. Also, since non-Support Follow-up kids would likely not be answering these additional questions on the form, we may need two different versions of the NF09A (Bayley III) in the data entry system. That could take a little more programming time to manage."

(2) Data analysis: Per Dr. Das, "As for the statistician effort, given that there are quite a few hypotheses to look at, I would estimate 4 weeks of full time work for data prep, additional cleaning if any, analyses, help with drafting the mansucript(s) and help with responding to journal reviews."

Hi Beena,
See my notations in the original email below...
Please advise how you'd like me to proceed. I'll be out of the office for a bit to get some lunch and pick up an oximeter from CHM. I should be back here by 2 pm. Otherwise, if it's easier, just email me back!

Thanks
Mary

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

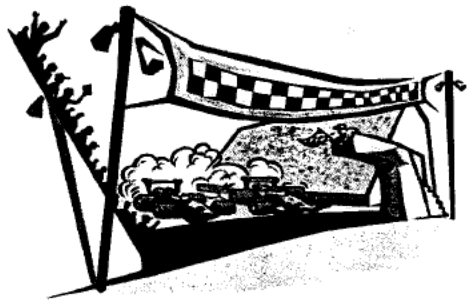
Enrollment



- Currently at 1247 by mid December
- I believe that we will be at 1310 by end February, end March at worst case
- We will discuss closure procedures within the month
- We will then need to have each enrolled infant reach final eye diagnosis etc.
- This could add another 20 weeks - 5 months or more – to August – Sept 2009

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

Preparation of Results of First set of Primaries

- We will visit RTI and spend a luxurious week basking in the > 1300 records
- We would then prepare the data, perform analyses, and write the first papers
- I would propose 2 papers – CPAP vs Surf and SpO2 Hi vs Low
- This will be followed by hundreds of subsequent ones!!

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

Follow-up

- **Need to follow through initial 18-22 months for other co-primaries**
- **Then to 6 years for extended follow-up for MRI and probably Breathing Outcomes**

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

Adverse Events

Type of adverse event	All infants	24-25 wks	26-27 wks
Chest compressions/epinephrine in DR	6.9	10.1	4.4
Air leak (pneumothorax, PIE, pneumopericardium)	9.7(8.2)	12.6 (11)	7.6 (6.1)
Pulmonary hemorrhage	6.7	10.5	4.0
Severe IVH (grades III-IV)	14.4	20.5	10.0

Note: Table includes SUPPORT infants who are still hospitalized and at risk for additional AEs

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

CURPAP Study

- Comparison of prophylactic surfactant

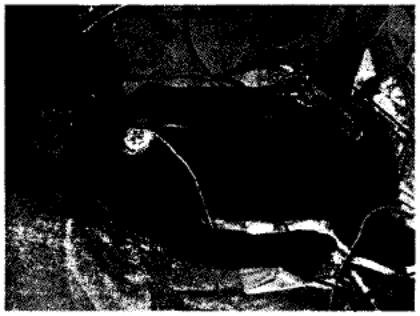
To nCPAP, with early Surf rescue

- Population: 25-28 weeks infants (European multicentre, n=24)
- Outcome:

. Duration of mechanical ventilation during the first 5 days of life

. Mortality, pulmonary and neurological morbidity

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.



CURPAP Study
Most recently reported

- 103 CPAP vs 105 Prophylactic Surf by 15 min, then extubated by 1 hour
- CPAP failure = Need for intubation, $FiO_2 > 0.40$, $PaCO_2 > 65mmHg$
- 50% of CPAP infants required rescue by 240 minutes (median)
- This is a relatively small study – COIN > 600complete

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

CURPAP Study 2008

Parameter	CPAP	Proph Surf
Gestational Age	27	27
Birth weight	913 + 200	967 + 221
Mortality	10.7%	8.6%
CPAP Failure	31%	33%
Pneumothorax	*1%*	*6.7%*
Survived with BPD	22%	23.8%

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

Protocol Deviations

- **Protocol Deviations – the commonest are timing issues – failure to give surf within an hour and failure to use the study oximeter when indicated**
- **8 centers with > 30% of enrolled patients with deviations, 2 with over 40%, most related to failure to use Study Oximeter when indicated.**

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

Oximeter Downloads

Months	Time on supplemental oxygen	Site	Number of hours	% 88-92	% <84	% 84-96	% >96
Oct08-Dec08	Days of life 1-14	All centers	4261	38.7	7.6	76.3	16.1
Jul08-Sep08	Days of life 1-14	All centers	10895	34.6	9.4	78.9	11.7
Oct08-Dec08	Day 15 to 36 wks	All centers	17707	23.8	13.6	66.5	19.9

Secondaries MRI

- Update on Neuroimaging secondary enrollment
- a. As of November monthly report – 455 patients with complete neuroimaging including near-term MRI
- b. We will likely have ~500-550 patients with complete neuroimaging by trial close.
- This will be the largest pre-term cohort followed to 6-7 years.

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

Neuroimaging

- Tracking tools and reports are now available through the SUPPORT data entry system on Centers' Network computers. The 3-4 year status form will be added to the system soon.
- b. Update on 18-22 month follow-up: As of mid-January 2009, ~100 patients with in Neuroimaging cohort with 18-22 month windows closed
- 91 of these have completed 18-22 month visit; 3 have been
- formally reported as lost to follow-up; 5 not yet seen; 1 reported to be seen at another NRN site

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

Other Secondaries

- Growth – 721 enrolled
- Breathing Outcomes - > 700
- Both Breathing Outcomes and SUPPORT – > 400
- Antenatal Consent – 2186 mothers approached, 972 delivered in Window, 1196 consents, 596 enrolled – about 3-4/1

This document is provided for reference purposes only. Persons with disabilities having difficulty accessing information in this document should e-mail NICHD FOIA Office at NICHDFOIARequest@mail.nih.gov for assistance.

Summary

- **Please continue with your efforts to enroll in SUPPORT.**
- **We are close to the end, and I believe that in view of the size and design, that this study will probably be the largest of its kind with important therapeutic implications.**
- **Thanks to everyone, especially the coordinators for a tremendous effort!!!**

Hello Everyone
I will give a brief report at the next Steering Committee this Friday. Attached are the current updates.
1. The enrollment is at 1247 as of Mid December. UI think that we can complete the trial by the end of February as we are 63 short at Mid December and we need 1310
2. The adverse events that we track are below the GDB baseline in both strata apart from air leaks. In this category we are slightly above the GDB baseline 9 12.6 &7.6% vs11% & 6.1%). The European CUROPAP trial was reported at the ESPR and they found a lower air leak rate in their CPAP infants than in the intubated group, but there is as yet no further details for this study.
3. Protocol Deviations – the commonest are timing issues – failure to give surf within an hour and failure to use the study oximeter when indicated
4. Oximeter downloads look the same as our past report. We do better in the first 14 days.
5. The Secondaries especially Breathing Outcomes > 700 enrolled, and MRImaging > 500 enrolled, are going well, with a large number of infants enrolled in both > 400 at last count
6. There will be a 6 year follow-up for the MR study and longer term School Age pulmonary evaluation is also planned – discussed at this meeting
7. Please continue with your efforts to enroll in SUPORT. We are close to the end, and I believe that in view of the size and design, that this study will probably be the largest of its kind with important therapeutic implications.

Thanks to everyone, especially the coordinators for a tremendous effort!!!
Neil

Percent of SUPPORT infants with selected adverse events as of December 16, 2008*

Type of adverse event	All infants	24-25 wks	26-27 wks
Chest compressions/epinephrine in DR	6.9	10.1	4.4
Air leak (pneumothorax, PIE, pneumopericardium)	9.7	12.6	7.6
Pulmonary hemorrhage	6.7	10.5	4.0
Severe IVH (grades III-IV)	14.4	20.5	10.0

Note: Table includes SUPPORT infants who are still hospitalized and at risk for additional AEs

Percent of GDB infants with selected adverse events and range across NRN centers*

(Includes infants born at NRN centers at 24-27 weeks GA in 2002-2004)

	All infants		24-25 wks		26-27 wks	
Type of adverse event	Percent	Range	Percent	Range	Percent	Range
Chest compressions/epinephrine in DR	11.2	3.2 - 31.8	13.9	2.8 - 42.1	9.1	3.2 - 23.2
Air leak (pneumothorax)	8.2	1.9 - 16.1	11.0	2.9 - 20.6	6.1	1.1 - 13.0
Pulmonary hemorrhage	9.0	3.4 - 29.3	12.3	2.5 - 32.0	6.5	1.1 - 26.9
Severe IVH (grades III-IV)	16.9	8.4 - 26.4	24.2	14.0 - 38.9	11.7	2.3 - 20.8

*Denominator for chest compressions is number of infants with delivery room information (SUPP03/NG02), denominator for air leak and pulmonary hemorrhage is number of infants with NICU data (NG03), denominator for severe IVH is number of infants with head ultrasound (SUPP09/NG03).

Rose and Betty,

Some thoughts about the discrepancy between 2004-5 and 2006 ELBW NDIs:

Since there is no reason for actual outcome to have changed dramatically over this time period, the much lower frequency of NDI reflects changes in test instruments and NDI definition used.....specifically the development criteria as the other components (neurologic, vision, hearing) have remained unchanged. It is not surprising that the Bayley-III cognitive scores are higher than the Bayley II MDI since language tasks and some fine motor tasks such as stacking blocks (areas in which our ELBW children are often delayed) are no longer included in the cognitive score. (Also, per Martha, a few items such as the yellow pegboard series seem to be more generously scored on the Bayley III compared to the Bayley II.I don't know if others have this same impression.) As a result fewer children will have cognitive scores < 70 which is now the only independent determinant of development disability. (The GMFCS ³2 is already used as the determinant for neurologic disability and is thus adding no new information to the developmental component.) It would be interesting to see what proportion of children had a PDI <70 which includes both fine and gross motor skills and a GMFCS < 2 which would have qualified them as NDI in 2004-5 but not in 2006.

Would combining the Bayley III cognitive and language scores result in a score closer to the Bayley-II MDI used previously? If so, perhaps we could use that composite cognitive-language score and moderate-severe CP (excluding the PDI) to define NDI more comparably between the two time periods. The 2006 NDI definition using cognitive < 70 or moderate-severe CP may be more predictive for future disability since motor delays unrelated to moderate-severe CP improve over time as does language function.

Since the incidence of NDI is so important in influencing counseling and medical support for the ELBW, it is important that we use a NDI definition yielding the most accurate prediction of longterm disability.

Yvonne

PS Happy New Year!

Subject:

Hi,

Attached is a Bayley score comparison from 2004-2006 – the 2006 year uses the new definition for cognitive score and the number of children with NDI is significantly reduced. Implications for this with ongoing studies and planned will be discussed on the Steering Committee PI call next week. Your input is needed. It would be helpful for site PI's to get thoughts from the FU PI's prior to the call, if possible.

Thanks

Rose

Subject: RE: SUPPORT Enrollment question

Brenda and Ivan,
You have our permission to continue to recruit patients into SUPPORT until the trial is finished. We are very close to completing recruitment, but want all eligible study subjects to continue to be approached for consent.

Thanks
Rose

Subject: SUPPORT Enrollment question

Hi Rose,
I am writing as Ivan had to leave town emergently. We have now enrolled 53 babies into the SUPPORT trial. When we reached our number previously we were allowed to use INS1 funds to continue enrolling up to 55 infants in SUPPORT. Now that we are so close to the 55 I was wondering once we hit 55 are we done enrolling or are we to continue until the overall number is reached? I need to know so when I leave for the meeting I have a plan in place for those left back in Boston who will be covering the study.
Thank you,
Brenda
