Subject: SUPPORT MRI study
Date: Friday, December 23, 2005 12:17:34 PM

Hi again,

Who should I ask from RTI to send another email re: how many sites plan to get/have gotten IRB approval for the secondary? Let me know if you think the following questions would give the information we need:

1) Has your site received IRB approval for the SUPPORT Neuroimaging secondary?
    a) If so, will your site be using a separate consent for the Neuroimaging secondary, or will the consent be embedded in the overall study consent?

2) If your site has not received IRB approval, has your site applied for IRB approval for the SUPPORT Neuroimaging secondary?
    a) If not, does your site intend to participate in the SUPPORT Neuroimaging secondary?

Thanks -

Susan

Rose:

I discussed with Marie your idea about using the face-to-face DSMC meeting to present interim monitoring data as well. It seems that, as far as efficacy is concerned, the first formal look is at 25% which would be 320 babies. Since we only have 243 enrolled, we're not there yet. However, we can share the latest safety looks with them (we do that roughly after every 60 babies).

Thanks

Abhik

Hi Wally

It will be good to have you at this meeting. Thanks for agreeing to participate.

I am attaching the latest PowerPoint. I know that you are traveling so have a look at it when you get home.

All the best for the Holidays

Neil

Hi Wally,

I understand you are on vacation and really hate to bother you; however, I have an important request. I think it would be good if you could attend the open portion of the DSMC meeting on the SUPPORT trial as you are the most active member of the subcommittee next to Neil. The meeting is possibly going to occur on January 24 in Rockville at the RTI offices. Let me know if this is a possibility.

Since you (b) (6) (if you have time)!!
Thanks

Rose

SUPPORT Trial
Response to the DSMC

Neil Finer – Principal Investigator

For the SUPPORT Subcommittee and the Steering Committee

NICHD Neonatal Research Network

December 11 2005

Report of the DSMC Nov 2005

The DSMC expressed 2 concerns:

1. There is a significant safety and exposure issue for the infants in the high saturation treatment group because an unacceptably high proportion of time was spent by these study subjects in the >95% range

Report of the DSMC Nov 2005

2. There is a futility concern for this arm of the trial in that there does not appear to be substantial separation between the two high and low saturation treatment groups, and the babies are not being kept in the target range the appropriate amount of time in order to meaningfully test the oxygen saturation intervention as originally designed.

Evidence for Current SpO2 Ranges

- **SUPPORT Trial alarm limits were chosen as those most currently utilized within the Network and consistent with current evidence.**
- **To maintain PaO2 between 40 and 90mmHg would require SpO2 alarms of 92.5% to 95% (Paky et al Acta Paediatr. 1995 Jun; 84(6):613-6.)**

Evidence for Current SpO2 Ranges

- **No current prospective studies have evaluated actual durations of time at various SpO2 levels**
- **Median SpO2 in healthy preterm infants in room air = 97% (Ng et al Arch Dis Child 1998;79:F64)**
- **All published studies reported target ranges ie lower vs higher High SpO2 alarm limits –(92% vs 95%) for populations but did not present any data as to how well these target were adhered to.**
- **Sun et al compared units with upper limits of >95% with those of ≤ 95% (Ped Res 2002, 51:350A)**

Evidence for Current SpO2 Ranges

- **Tin et al reported units by the limits they set without any individual patient data (Tin et al Arch Dis Child 2001;84:F106)**
- **Another survey compared SpO2 limits > 98% with ≤ 98%, and early limits – first 2 weeks- of > 92% vs < 92%**

  (Anderson Ped Res 2002;51:367A)
- **Chow et al reported on a change of practice including lowering of the SpO2 limit – They did not provide any actual SpO2 data (Chow et al, Pediatr 2003;111:339)**
- **All of these studies suggested that lower SpO2 limits were associated with less ROP.**

Evidence for Current SpO2 Ranges

- **Prior to the initiation of SUPPORT – there were no data indicating the actual percent of time ELBW infants spend at different SpO2 values or ranges**
- **The design of the trial using oximeter downloads was unique and will provide this information based on a large prospective cohort**
- **This trial was also unique in collecting this data from 2 hours of age in acutely unstable ELBW infants until they are out of oxygen for 3 days.**

Response to DSMC

Safety Issue of SpO2>95%

Concern regarding safety issue of duration of SpO2 > 95%

- ✓ **The current best evidence utilizing actual oximeter data is from Hagadorn et al (PAS 2004 Abstract: Late Breaker)**
- ✓ **Evaluated 78 ELBW infants for 70 hours per week for the first 4 weeks of life**
- ✓ **Lower and upper SpO2 limits were 83% -92% and 92%-98%**
- ✓ **Median SpO2 = 95%**
- ✓ **Medians from SUPPORT Oximeter groups – 92% and 94% overall, , and 91% vs 93% for infants only in oxygen for the entire day.**

Response to DSMC:
Safety Issue of SpO2>95%

- STOP-ROP high treatment infants spent 97% of time > 95%
- Case Western a current NRN Center – Current data from SUPPORT type ELBW infants – SpO2 > 95% for > 50% time
- SUPPORT Infants on room air – SpO2 > 95% from 46% to 69% of time

Response to DSMC:
Safety Issue of SpO2>95%

- **Additional analyses evaluated the duration of time at SpO2 values of 98%, 99% and 100% as these may represent very high PaO2 values**
- **Infants in SUPPORT in ROOM Air spend 32% - 38% at these values.**
- **Infants in SUPPORT in Oxygen spend 5%-6% at these values.**

SUPPORT Trial Results - N=111, 26,889 hours

91% - 95% Room Air 85% - 89%

	%	Cum %	%	Cum%
98%	15.49%	77.15	13.65%	81.42
99%	12.94%	90.09	10.37%	91.79
100%%	9.91%	100.00	8.21%	100.00
Total	38.3%		32.2%	

91% - 95% Oxygen 85% - 89%

98%	3.51%	96.90	2.66%	97.23
99%	1.90%	98.80	1.60%	98.83
100%	1.20%	100.00	1.17%	100.00
Total	6.6%		5.4%	

Response to DSMC: Safety Issue of SpO2>95%

- **The algorithm for conversion of displayed versus actual values results in inability to create a whole value for each displayed value.**
- **The data evaluated by the DSMC had an overestimation of durations > 95% due to rounding errors inherent in the algorithm. Thus values of 95% are considered to be > 95%**
- **This represented greater than 6% of the initial calculated durations > 95% for the 91%-95% group**

Response to DSMC: Safety Issue of SpO2>95%

- **In an effort to provide better information regarding both high and low SpO2 values and avoid the problem with the re-conversion algorithm, we asked for analyses for durations > 96% and < 84% as these are values which do not require conversion and are always unaltered.**

Response to DSMC: Safety Issue of SpO2>95%

- ✘ Any calculations which incorrectly assigned infants on room air to be analyzed as receiving Oxygen would overestimate the durations > 95%
- ✘ Our data forms only reported 3 FiO2 data points daily for the first 14 days and then only a single daily value thereafter.
- ✘ Thus we were using oximeter data and assigning it based on these data points to determine the true days in oxygen
- ✓ Reanalysis based on assigning the infant to oxygen only if all 3 points for the day had an FiO2 > .21 showed markedly lower durations of SpO2 > 95% and greater than 96%

Response to DSMC: Safety Issue of SpO2>95%

Percent of time of spent at SpO2 < 84% and > 96%

RTI Analyses In Oxygen
Dec 2, 2005, N = 166, 102, 673 hrs

Range Assigned	High target (91-95)	Low target (85-89)
< 84%	8.30%	14.05%
> 96%	21.45%	15.47%

Response to DSMC:
Futility regarding Separation of Oximeter Groups

- **Further analyses including only infants on Oxygen at all 3 data points for a given day**

RTI Analyses In Oxygen all 3 Points,

Dec 5, 2005, N = 127, 16,216 hrs

Range Assigned	High target (91-95)	Low target (85-89)
< 84%	6.40%	13.3%
> 96%	12.5%	9.39%

Response to DSMC: Safety Issue of SpO2>95%

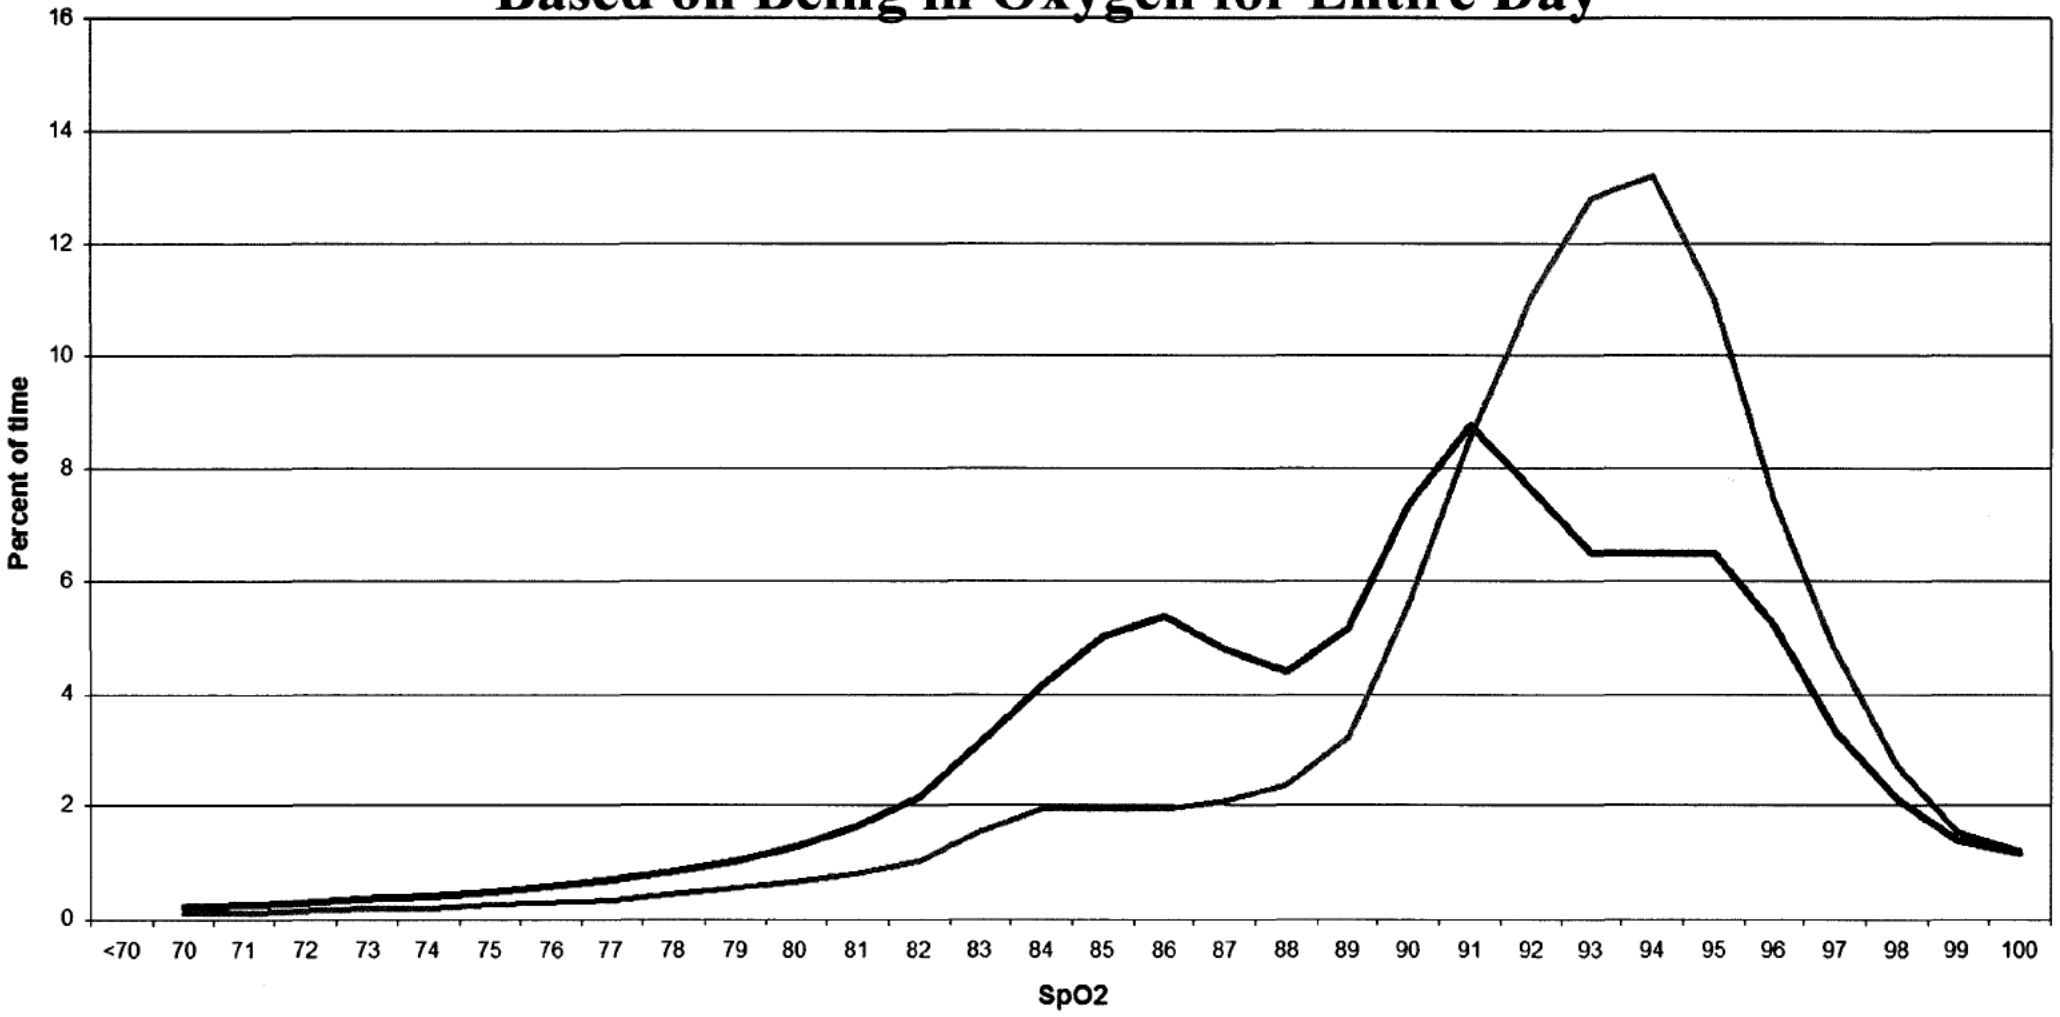
- **We believe that neither oximeter group in the SUPPORT trial is being exposed to excessive durations of SpO2 > 95% based on all currently available information and the actual SUPPORT Trial Data analyzed to date.**
- **Current analyses demonstrate that the highest duration of SpO2 > 95% was 22.9%, and > 96% was 12.5% using only infants known to be in oxygen for all 3 daily data points in the first 14 days of life.**
- **These values are previously unreported for such a population, and significantly less than the original data reviewed by the DSMC.**

Response to DSMC:

Futility regarding Separation of Oximeter Groups

- **An evaluation of the oximeter group data has revealed that there is a difference in the Mean – (90% vs 92%) and Median – (92% vs 94%) values for the 2 groups overall.**
- **The Median SpO2s obtained using only days that were in oxygen at all 3 data points were 91% vs 93%**
- **Cumulative time spent with an SpO2 of 90% or less shows an absolute difference of > 24% (22.80% -91% - 95% Group versus 47.6% -85% - 89% Group)**
- **91%-95% Group spends 77.2% of time > 90% compared with 53% for 85%-89% Group**

Percent of Time at Each SpO2 value (Smoothed data)
Based on Being in Oxygen for Entire Day



Slide 19

P9 Maybe just "Oxygen Days" ? I would make first title bigger and second smaller.
Pediatrics, 12/16/2005

Response to DSMC:
Futility regarding Separation of Oximeter Groups

- **We examined the FiO2 requirement of the infants in the Oximeter arms.**
- **If the algorithms were working as intended, then there should be a difference in the FiO2 requirement between the groups**

Response to DSMC:
Futility regarding Separation of Oximeter Groups

- **The time spent in Room Air during the first 14 days of life was 26.6% versus 35.5% for the 91%-95% group compared to the 85%-89% group.**
- **These differences persisted for data beyond 14 days**
- **The 2 groups remained separated by at least 3% duration for FiO2s of $\leq$ 50%**

Response to DSMC:
Futility regarding Separation of Oximeter Groups

- **The time in Target using only days when infants are in oxygen for all 3 data points**

91-95% = 55% 85% - 89% = 24.6%

Response to DSMC:
Futility regarding Separation of Oximeter Groups

- **The 91% - 95% Group are more in target because their alarm sounds when they reach 95%**
- ✘ **For the 85% - 89% real SpO2 values > 89% to < 92% do NOT alarm. The alarm only sounds at a reading of 95%**
- ✓ **We believe that we can improve this time in range by lowering the high alarm to 94%**

Response to DSMC:
Futility regarding Separation of Oximeter Groups

- **It is uncertain what duration of differences in either SpO2 or FiO2 will be associated with different short and long term outcomes, but we are achieving some separation in both to the present.**
- **We believe that greater separation is possible and desirable and have made a number of recommendations to ensure that this will occur.**

Response to DSMC:

Suggestions for Increasing Separation of Oximeter Groups

1. **Set high SpO2 limit – alarm to 94%. This will reduce the duration of SpO2 values > 95% for both groups, and should increase the time both groups spend in the narrow target range.**
2. **Require documentation that the oximeters alarm limits are set and functional as per protocol every 4-6 hours**
3. **Change our data collection for FiO2 to ensure that subsequent interval reports more accurately reflect saturations measured while on oxygen therapy and exclude saturations of infants in room air**

Response to DSMC:

Suggestions for Increasing Separation of Oximeter Groups

4. Further training and in-service at all the sites to stress the importance of keeping the SpO2 alarms functional and at the limits of 85% and 94%. We will use the OWL (Oxygen with Love Program) developed at Oschner.
5. Develop guidelines for managing desaturations such that the increase in oxygen is proportional to the desaturation
6. Place bedside cards to indicate the desired target range

Response to DSMC:

Suggestions for Increasing Separation of Oximeter Groups

7. Initiate compliance monitoring visits coordinated by RTI to visit random sites
8. Reanalyze group differences after an additional 100-150 infants have been enrolled.
9. Utilize only actual SpO2 values for assessment of safety in subsequent analyses ie; SpO2 < 84% and > 96%, and analyze only actual time in oxygen.

Response to DSMC

- **The SUPPORT Trial Committee and the Network Steering Committee appreciate the diligence and suggestions of the Data Safety Monitoring Committee**
- **We trust that our response and suggestions to improve the SUPPORT Trial are found acceptable and that we may be allowed to continue this important trial.**

Subject: RE: SUPPORT ANCILLARY -Emory
Date: Monday, December 19, 2005 11:11:52 AM

Hi Barbara and Rose

If this study is intended as SUPPORT Secondary then the protocol should follow the SUPPORT Criteria ie infants of 24 0/7ths to 27 6/7ths and not include 28 week infants.

Barbara, do both of your sites enroll in SUPPORT?

I assume that the non intubated CPAP infants would not have a tracheal aspirate specimen sent.

Will this then qualify as a Secondary for the SUPPORT Trial as there will be fewer specimens from the CPAP group? (This is an assumption on my part)

However there is no intervention apart from obtaining a tracheal aspirate, and including infants in SUPPORT is not a problem as I read this protocol.

I believe that this study can move ahead.

I can send to the committee, but unless I have misread the protocol there is no interference with SUPPORT.

Let me know if either of you feels that this should be circulated.

Neil

OK - but I am not sure that is reasonable - a way to go around the DSMC? Through Dr. Alexander? Should I call Spong? Should I raise a fuss or just let it lie. The DSMC thing is broken at NICHD (should not have stopped the antenatal steroid trial) - can I use this to start to get it fixed - a parting shot?

The effects of oxidative stress on the neonatal alveolar macrophage- an ancillary study

December 16, 2005

A. Abstract

Premature newborns are at increased risk of pulmonary infection due to the immaturity of inflammatory cells, including the resident alveolar macrophage. The macrophage is the first line of defense against infection in the lung. Glutathione, (**GSH**) a major antioxidant in the lung, is required by the macrophage to maintain redox potential and optimize intracellular functioning. Levels of systemic and alveolar GSH are deficient in the premature newborn, placing the lung at increased risk for oxidant injury and cellular dysfunction. We ***postulate*** that the pulmonary GSH deficiency caused by prematurity is exacerbated when superimposed on exaggerated oxidant stress, such as that caused premature delivery, oxygen therapy and mechanical ventilation. We ***further postulate*** that increased oxidant stress for the resident macrophage contributes to impaired macrophage maturation and function in the premature newborn.

Studies of chronic oxidative stress from adult and fetal animal models from our laboratory have demonstrated that alveolar macrophage dysfunction contributed to a decreased clearance of bacteria from the lung, increasing bacterial sepsis and pneumonia *in vivo*. *In vitro* analysis of premature alveolar macrophage phagocytosis was improved with exogenous GSH, while apoptosis and malonyldialdehyde, a marker of severe oxidant stress were decreased with exogenous GSH. Furthermore, alveolar macrophage function correlated with the maturity of the cell. In preliminary clinical studies from premature intubated babies (n=12, birth weight ~759gms, gestational age ~26 wks), tracheal aspirate GSH was inversely related to hydrogen peroxide (H_2O_2) content, suggesting that as the oxidative stress in the airway increased, the availability of GSH decreased. Furthermore, Fas ligand, a strong apoptotic signal for cells positively correlated with H_2O_2 and negatively correlated with GSH. The ***in vitro*** phagocytic function of isolated alveolar macrophage from these premature newborns was significantly increased and apoptosis was significantly decreased by exogenous GSH. **We hypothesize that the oxidative stress of prematurity jeopardizes macrophage GSH, and resulting in increased macrophage oxidant stress, dysfunction and impaired maturation. Furthermore, we hypothesize that increased markers of oxidant stress in the tracheal aspirate correlate with delayed alveolar macrophage maturation and dysfunction.**

B. Statement of the Problem: Premature newborns are at increased risk of oxidant stress and pulmonary infection. Glutathione, (**GSH**) a major antioxidant in the lung, is required by immune cells such as the resident alveolar macrophage to maintain redox potential and optimize intracellular functioning. Levels of systemic and alveolar GSH are deficient in the premature newborn, placing the lung at increased risk for oxidant injury, macrophage dysfunction and risk of infection. The ability to identify the premature patient at risk for increased oxidant stress and alveolar macrophage dysfunction is clinically lacking. Furthermore, a better understanding of the role of the maturation of the alveolar macrophage in immune defense in the premature lung is necessary for the optimal care of these patients.

C. Hypothesis: We ***hypothesize*** that the oxidative stress of prematurity jeopardizes macrophage GSH, and resulting in increased macrophage oxidant stress, dysfunction and impaired maturation. Furthermore, we ***hypothesize*** that increased markers of oxidant stress in the tracheal aspirate correlate with delayed alveolar macrophage maturation and dysfunction.

D. Specific Aims

Aim 1- To determine whether oxidative stress markers on the alveolar macrophage of premature newborns correlate with alveolar macrophage maturity and apoptosis.
Aim 2- To determine whether neonatal alveolar macrophage maturity correlates with ***in vitro*** function and viability.

E. Rationale/justification

The premature lung is under enhanced oxidative stress. Glutathione (**GSH**)(g-glutamyl-cysteinylglycine) is an essential antioxidant in the body. GSH is normally present in high concentrations in the epithelial lining fluid (**ELF**) of the lung through active transport from the plasma to the alveolar space. In the premature newborn, plasma GSH is decreased; therefore, the alveolar GSH concentration is subsequently decreased, increasing the risk of oxidative stress in the premature lung (1-3). Indeed, GSH levels in the broncho-alveolar lavage of premature infants are inversely related to the development of CLD (2, 4). Therefore, the premature lung is a "low GSH environment" at risk for oxidant-induced injury. Furthermore, common clinical conditions have been associated with increased oxidant stress including include maternal diabetes, maternal smoking, pregnancy-induced hypertension, intrauterine growth retardation, and preterm premature rupture of membranes (5-9). **Therefore, the premature newborn is at risk of exaggerated oxidant stress.**

Understanding the functions of the neonatal alveolar macrophage is important. As the resident inflammatory cell in the lung, the alveolar macrophage provides the initial defenses for the lung against foreign and infectious particles. A professional phagocytes, the alveolar macrophage defends the lung by initiating and regulating the inflammatory process and has the responsibility to phagocytose and clear infectious particles. The majority of alveolar macrophages are derived from peripheral circulating blood monocytes. The monocyte precursors within the systemic circulation constitutively move into the interstitial space of the lung and differentiate into mature alveolar macrophage in the alveolar space. Alveolar macrophage precursors are also recruited to the lung in response to pro-inflammatory stimuli. Therefore, the normal population of alveolar macrophage is a heterogeneous mix of immature and mature cells in the human, (10). These populations of cells demonstrate functional variability in their ability to ingest organisms and release cytokines in response to infectious stimuli. The alveolar macrophage's response to inflammation, the clearance of infection and the termination of the inflammatory response all contribute to the inflammatory state of the lung. With inflammatory states, chronic disease, infection and adult respiratory distress syndrome, the heterogeneity of the alveolar macrophage population is altered to a more immature, monocytic phenotype, and these changes in macrophage population and function contribute to the severity of the local disease state in the lung (11-14). **Therefore, a better understanding of the maturation of the alveolar macrophage population in the developing lung would advance the care of the premature newborn.**

Glutathione is necessary for alveolar macrophage functioning. In the newborn infant, particularly the premature newborn, the function of the alveolar macrophage is also impaired (15, 16). Within the lung, GSH is an essential substance for the resident cells of the airway, including the alveolar macrophage. The alveolar macrophage is dependent on the availability of extracellular GSH to maintain intracellular concentrations of GSH during hyperoxia (17). The intracellular antioxidant defenses of the macrophage and its phagocytotic ability are dependent on a functional intracellular GSH redox system (18, 19). With exaggerated intracellular oxidative stress, the increased production of reactive oxygen species within the macrophage exceeded the cell's ability to detoxify them, contributes to its own demise via programmed cell death or apoptosis (20). **Therefore, increased oxidant stress in the lung causes dysfunction and apoptosis of the alveolar macrophage, decreasing the lung's defenses against bacterial infection.**

Chronic oxidative stress increases the risk of infection in several disease states. The chronic depletion of antioxidants such as GSH has been well described in other pediatric conditions such as

cystic fibrosis. With chronic GSH depletion, the inability to increase epithelial lining fluid GSH in response to infection contributes to the increased risk of pulmonary infections characteristic of cystic fibrosis (21, 22). Chronic oxidative stress and decreased GSH availability also contributes to alveolar macrophage dysfunction and the increased risk of infection and acute lung injury in adults alcoholics (23-28). Premature newborns are well known to be at an increased risk of infections (29-32), increasing morbidity and adverse outcomes for the premature newborn (33, 34). **However, the relationship between oxidant stress, alveolar macrophage maturation and infection risk in the premature remains under investigation.**

F. Background / Previous Studies

1. Chronic oxidant stress impairs alveolar macrophage clearance of bacteria *in vivo*. Recent studies in our laboratory have investigated the effects of chronic oxidative stress on alveolar macrophage function in the adult rat and the newborn guinea pig. Using chronic ethanol (E) exposure as a model of chronic oxidant stress and diminished GSH availability in the adult lung (28), we examined the clearance of bacteria from the lung *in vivo*. In preliminary experiments, bacterial clearance of *group B strep* (GBS) was dramatically diminished with E exposure. Systemic blood culture demonstrated an over 200 fold increase in growth in the E animal compared to control (Control 22 ± 10 vs E 4,866 ± 1,737 colony forming units (CFU), p=0.1). Furthermore, E exposure significantly decreased bacterial clearance in lung homogenates (Control-67 ± 35 CFU vs. E-1400 ± 305 CFU $p<0.05$). In a guinea pig model of *in utero* oxidant stress and diminished GSH availability due to fetal E exposure (35), term guinea pigs were evaluated for clearance of experimental GBS. Bacterial clearance was dramatically diminished in the blood (Control 41.3 ± 41 CFU vs E-12,500 ± 2,500 CFU) and in the lungs (Control 0.50 ± 0.58 vs E- 90.5 ± 3.5 CFU)of E exposed pups compared to control. Furthermore, alveolar macrophage phagocytosis of the GBS was diminished in E exposed pups compared to control (Control- 96.3 ± 3.7% positive vs E- 56.8 ± 13.5% positive). **Therefore, chronic oxidant stress of ethanol exposure diminished alveolar macrophage phagocytosis of experimental GBS, decreasing bacterial clearance in the lung and increasing sepsis in these animal models.**

2. GSH improves fetal alveolar macrophage phagocytosis and viability *in vitro*. Our laboratory has evaluated premature alveolar macrophage function using the timed-pregnant guinea pig (term 72 days) (35). Alveolar macrophage were isolated from 55 day pups by bronco-alveolar lavage and incubated with FITC-labeled inactivated staph aureus for 4 hrs. *In vitro* analysis has demonstrated that exogenous GSH (200 μM *in vitro*) significantly improved the phagocytic index (PI= relative fluorescent units of FITC-labeled staph aureus/cell x % of cells positive for any fluorescence) of the premature alveolar macrophage (- GSH 1742.57 ± 90.54 vs. + GSH 2243.51 ± 154.19, $p<0.05$). Additional experiments have demonstrated that the maturity of the alveolar macrophage, as determined by a guinea pig marker, significantly correlated with the function of phagocytosis (Spearman Rank order 0.25, p=0.017). Apoptosis of the alveolar macrophage was also significantly diminished with exogenous GSH *in vitro* (–GSH 22.92 ± 3% of the cells vs. + GSH 15.8 ± 1.1%, $p<0.05$). Finally, malonyldialdehyde, a lipid peroxidation product and a marker of severe oxidant stress on the alveolar macrophage was also significantly reduced with the addition of GSH *in vitro* (– GSH 31.6 ± 2.8% of cells positive by immunofluorescence vs + GSH 23.9 ± 2.7 %, $p<0.05$). **These results suggested that exogenous GSH improved function and viability of the premature alveolar macrophage, decreasing oxidant stress.**

3. Oxidant stress is present in the airway of premature newborns. We isolated and examined tracheal aspirate fluid (**TA**) and macrophage from intubated premature newborns within 24 hr of

intubation. Twelve patients with birth weight 759 ± 80 gm and gestational age 25.7 ± 0.1wk were evaluated. The majority had hyaline membrane disease (10/12) and received surfactant therapy (10/12). The TA was evaluated for GSH and its oxidized portion GSSG via HPLC(28, 35). Hydrogen peroxide (H_2O_2) in the TA was measured via colorimetric assay. The ratio of GSH/GSSG in the TA negatively correlated with H_2O_2 (Pearson -0.829, $p<0.05$), suggesting that as the oxidative stress in the airway increased, the availability of GSH decreased. Because soluble Fas ligand (**FasL**) has been associated with an acute inflammatory state and is a strong apoptotic signal for cells such as neutrophils and type II epithelial cells, (36, 37)(23, 27) we measured FasL in the TA. H_2O_2 positively correlated with FasL (Pearson: +0.916, $p<0.01$), while GSH/GSSG negatively correlated with FasL (Pearson: -0.991, $p<0.01$). **These results support the hypothesis the imbalance of oxidative stress and decreased GSH/GSSG may contribute to increased signals for cellular oxidative stress and apoptosis in the premature airway.**

4. Function and viability of premature newborn alveolar macrophage was improved with exogenous GSH *in vitro*. The premature alveolar macrophage were evaluated *in vitro* for phagocytosis and apoptosis. The addition of GSH (200 μM for 4h *in vitro*) nearly doubled the phagocytic index of the cells (PI without GSH- 2368 ± 321 vs PI with GSH 4062 ± 389). Although the cells were uniformly viable at the time of isolation as measured by the calcein/ethidium iodine Alive-dead stain,@ the addition of GSH (200 μM) *in vitro* dramatically reduced macrophage apoptosis by ~70% (52.6 ± 4% vs 15.7 ± 1%, $p<0.01$). **Therefore, these data suggest that the addition of GSH to the culture media improved function and viability of premature alveolar macrophage.**

G. Method/ Procedures

*1. **Description of study design:*** This proposal would be an Ancillary study to the current SUPPORT trial. Since the analyses focus on the relationship between oxidant stress markers and alveolar macrophage maturation, each baby's sample would be compared to itself. With the exception of sample collection, there is no intervention to the patient.

2. Definition of study population (with inclusion/exclusion criteria)

Patient Population: Tracheal aspirate samples will be obtained for alveolar macrophage analysis from participating NICHD NICUs. Locally at the Emory University NICUs, tracheal aspirate samples will be obtained for alveolar macrophage analysis and fluid analysis from two hospitals (Crawford Long Hospital and Grady Hospital) within the Emory University Division of Neonatology system.

Patient Enrollment: After admission to the neonatal intensive care unit, patients will be evaluated for enrollment in the study.

Inclusion criteria: All newborns admitted to the NICU with gestational age of 24-28 weeks who require endotracheal intubation will be eligible for enrollment.

Exclusion criteria: Patients with suspected chromosomal abnormality, positive maternal HIV, or refusal of consent are excluded. Patients deemed non-viable by the attending neonatologist will not be approached for enrollment. An HIV history will be exclusion because of the potential risk to laboratory personnel in the sample handling and subsequent fluid and macrophage analysis.

3. Description of study intervention

Tracheal Aspirate Sample collection: After verbal informed consent (Emory Univ IRB, Gauthier #388.99), the TA will be obtained at the time of routine endotracheal suctioning at <24 hrs after intubation, daily for 3 days, day 7 and then weekly until the baby is no longer on the ventilator. For the suctioning procedure, bacteriostatic saline (~1 cc) is instilled into the trachea and after several ventilator breaths the sample is retrieved into a closed, sterile (Leukins) trap. The sample will be obtained after suctioning is performed for clinical indications. Patients and samples will be identified with a study number to ensure confidentiality. The PI will match study numbers to medical record numbers, with confidentiality maintained. Universal sterile technique will be used for all sample handling and processing. For samples obtained from distant NICHD NICU's, the sample will be immediately transferred into a labeled test tube containing fixative media and labeled with the study number. These sampled would be shipped to the Neonatology Laboratory of Emory University, Atlanta, GA. For samples collected locally in Atlanta, the labeled sample will immediately be placed on ice and transported to the Neonatology laboratory. Sample collection is straightforward and easy, requiring minimal time and preparation.

4. Precise definition of primary/secondary outcomes

Primary Outcome (all samples)- The correlation between alveolar macrophage oxidant stress and the alveolar macrophage's maturational profile.

1. Macrophage oxidant stress- Fixed alveolar macrophage will be recovered from the TA and evaluated under fluorescent immunohistochemistry for markers of oxidant stress including malonyldialdehyde (MDA) and hydroxynonenal (HNE) (35).
2. Macrophage maturational profile will be evaluated by fluorescent confocal microscopy as outlined in **Table 1** below. Macrophage apoptosis will be measured by fluorescent cleavage of poly (ADP-ribose) polymerase (PARP), an early indicator of the apoptosis pathway (38).

Table 1 Evaluation of alveolar macrophage maturational profile

Cell Characteristic	*Mature*	*Immature*
Size	Large	Small
Nuclear/Cytoplasmic Ratio	Low	High
Markers	CD 14 low/CD11b low/CD32 high, Mannose Receptor high/ FCγRIII high	CD 14 high/ CD11b high/CD32 low/Mannose Receptor low/ FcγRIII low
Apoptosis	Decreased	Increased

Secondary Outcomes (to be evaluated on local samples in Atlanta):

1. The correlation between alveolar macrophage phagocytic function and maturational profile as described above. *In vitro* analysis of alveolar macrophage phagocytic function will be examined using inactivated FITC-labeled staph aureus.

2. The correlation between TA oxidative stress (GSH/GSSG, H_2O_2) and alveolar macrophage maturational profile and cell oxidative stress will be evaluated as described above. TA GSH/GSSG will be measured via HPLC while H_2O_2 will be measured via colorometric assay. Cellular protein-bound GSH status will be also evaluated on fresh alveolar macrophage using a primary antibody to GSH.

5. Sample size estimate with some statistical support (including estimate of compliance and consent rates) based upon primary outcome.

In order to detect the strength of a correlation between macrophage oxidant stress markers and maturational profile, and function and maturational profile, we will assume that the data is not normally distributed and the variables are neither dependant nor independent of each other. Using Sigma Stat for Windows and the Spearman Rank Order Correlation, we will calculate the Spearman correlation coefficient **rs**. Assuming a negative correlation coefficient of -0.4 (as oxidant stress increases, maturation decreases) or positive +0.4 (as maturation increases, function increases) we will need a sample size of 47 patients with an alpha of 0.05 and a 0.8 power. Our current consent rate at the Emory University hospitals is ~67% of eligible infants.

6. Available population/compatibility with other ongoing protocols. Locally at the Emory University NICUs, tracheal aspirate samples will be obtained for alveolar macrophage analysis and fluid analysis from two hospitals (Crawford Long Hospital and Grady Hospital) within the Emory University Division of Neonatology system. Both hospitals have active delivery services in the city of Atlanta. Crawford Long Hospital delivers ~ 3,600 deliveries/year, serving both suburban and urban patients. Crawford Long Hospital has a new 25 bed Level III Neonatal Intensive Care nursery. Grady Hospital serves predominantly the urban community with ~4,000 deliveries/year and is equipped with a ~60 bed Level III Neonatal Special Care nursery. From Grady hospital and Crawford long hospital infants <1500 g and requiring intubation totaled 126 infants in 2003. This proposed analysis of alveolar macrophage should not interfere with other ongoing trials. Study medications or other interventions (if applicable) will be noted during the macrophage analysis.

7. Estimate of projected recruitment time

We estimate that 1 year will be needed to recruit and obtain enough clinical samples to obtain statistical significance in the macrophage analysis as described above. Enrollment from the entire network would increase enrollment from approximately 10 patients per month to approximately 30 patients per month.

H, Risks/benefits, with estimate of frequency/severity of risks.

The intervention of tracheal suctioning is not without risks of infection/damage to the airway. However, we propose to evaluate cells and tracheal aspirate fluid obtained from routine tracheal suctioning, when used only for clinical indications, as per individual NICU routine. Therefore, there are no other risks to the patient from this proposal. There are no direct benefits for the individual subjects to participate in this proposal.

Yes; I think this is a very good idea and would show the DSMC our seriousness with respect to the separation issue. I would suggest just weaving it into Neil's presentation as part of the steps we would take to address the separation issue (maximum 2 slides), and give more details only if asked for (would keep them handy though, just in case).

Thanks

Abhik

HI,
This information is helpful - one word of caution though. I think we have given the DSMC a fair bit of material thus far. Perhaps the summary document is appropriate, but I am concerned that the entire package may be a bit too much. Others thought would be appreciated, especially Ken and Abhik.

Thanks
Rose

Hello Rose and Everyone
I would like you to look at this information. I believe that we could use this as we plan to move ahead with SUPPORT to encourage better attention to oximeter alarms. Would you let me know if you think that some or all of these materials would be useful for SUPPORT?
I have asked for permission to use in the Network and Jay Goldsmith has already said yes.
The tentative DSMC meeting looks like Jan 24th in DC.
Thanks
Neil

Subject: OWL

Enclosed is the information that you requested from Dr. Goldsmith. Attached are the documents we used to get started. There is the Potentially Better Practice Sheet, The contract we had each employee sign, a copy of the Logo, the worksheet for data collection, a copy of the bedside summary, (was laminated and placed at each OWL's bedside), and the form used to do the q shift walk throughs for compliance.

We did not have any special materials for the family. There was a copy of the protocol guidelines attached to each OWL's bedside, and for those who asked, an explanation of the protocol was given.
We did not get any negative feedback from the staff in relation to the families, just a sense of a greater need of awareness for the nurses and therapists at the bedside.
When we initiated the protocol all babies under 1500 gms were but on the protocol, even those that had been with us prior to the date of initiation.
We did not experience any complaints or major problems with the implementation or the families awareness of it.
I also attached a power point presentation that we used to initiate the education to the unit.We started with the Neo Docs and had them all agree that this would be a change of policy and unit protocol to be followed by all unless an order was written with a substantiated reason for not following the protocol.
The frequent alarms and frequent changes in the o2 sats and requirements are part of the deal. We found there is a period of time that all of the micro premies experience this and it stops with time. It can be very challenging for the bedside nurse. You may find the contract helpful. We also found the nurses took personal responsibility for making sure their primary did not need cryo.
We also have a large amount of very senior staff. We did have small amount of trouble with compliance in the beginning.
We did a large amount of education prior to initiating the change. We published (in the unit) our numbers compared to the national average, (our numbers were much worse). I kept the staff updated with current data, what their compliance was as well as our ongoing ROP numbers.

Subject: Breathing Outcomes Study

Hi Neil and Rose,

With the main SUPPORT Trial on hold, many coordinators have not taken the
Breathing Outcomes Study to their IRBs and some IRBs have been reluctant

to
consider an amendment allowing the Breathing Study to go forward.

With your consent, I'll prepare a cover letter and consent form for the coordinators to present to their IRB explaining that the Breathing Outcome
Study population is infants already enrolled in SUPPORT and that, while the
main trial is on hold, the follow up windows (timepoints) are passing and
cannot be recouped. The letter will request IRB review so that patients currently enrolled in SUPPORT may be approached for consent, using a consent
form separate from the SUPPORT consent, authorizing enrollment into the Breathing Outcome Study. The letter will emphasize that no new recruitment
into SUPPORT will occur until the study officially resumes.

If this is OK with you, I'll get it out this week.

Thanks

Tim

---

Hello Rose and Everyone
I would like you to look at this information. I believe that we could use this as we plan to move ahead with SUPPORT to encourage better attention to oximeter alarms. Would you let me know if you think that some or all of these materials would be useful for SUPPORT?
I have asked for permission to use in the Network and Jay Goldsmith has already said yes.
The tentative DSMC meeting looks like Jan 24th in DC.
Thanks
Neil

Subject: OWL

Enclosed is the information that you requested from Dr. Goldsmith. Attached are the documents we used to get started. There is the Potentially Better Practice Sheet, The contract we had each employee sign, a copy of the Logo, the worksheet for data collection, a copy of the bedside summary, (was laminated and placed at each OWL's bedside), and the form used to do the q shift walk throughs for compliance.

We did not have any special materials for the family. There was a copy of the protocol guidelines attached to each OWL's bedside, and for those who asked, an explanation of the protocol was given.
We did not get any negative feedback from the staff in relation to the families, just a sense of a greater need of awareness for the nurses and therapists at the bedside.
When we initiated the protocol all babies under 1500 gms were but on the protocol, even those that had been with us prior to the date of initiation.
We did not experience any complaints or major problems with the implementation or the families awareness of it.
I also attached a power point presentation that we used to initiate the education to the unit.We started with the Neo Docs and had them all agree that this would be a change of policy and unit protocol to be followed by all unless an order was written with a substantiated reason for not following the protocol.
The frequent alarms and frequent changes in the o2 sats and requirements are part of the deal. We found there is a period of time that all of the micro premies experience this and it stops with time. It can be very challenging

for the bedside nurse. You may find the contract helpful. We also found the nurses took personal responsibility for making sure their primary did not need cryo.
We also have a large amount of very senior staff. We did have small amount of trouble with compliance in the beginning.
We did a large amount of education prior to initiating the change. We published (in the unit) our numbers compared to the national average, (our numbers were much worse). I kept the staff updated with current data, what their compliance was as well as our ongoing ROP numbers.

Oxygen saturation targeting to decrease oxygen's toxic effects

– Brought to you by the Ochsner Vermont Oxford Respiratory Group

OXYGEN TARGETING

- -used to decrease the risk of ROP and the need for interventional surgery; as well as other side effects of oxygen toxicity.

This is not a study!

It is a change in the way we **Practice**

Why?

- A recent multicenter study showed that 30% of infants with ROP that reached threshold and received surgery, had unfavorable vision as long as 10 years out
- We need to not only reduce the incidence of the need for surgery but decrease the number of infants that reach threshold disease

GOALS

- Decrease the incidence of ROP
- Decrease the need for interventional surgery
- Decrease total days on the ventilator
- Decrease the total days in oxygen
- Decrease length of Hospital stay

PLAN

- All admits 500-1500gms
- Oxygen or ventilator dependent
- Pusle oximeter alarms to be set at 80-95 with the goal being to keep saturations greater than 85 but less than 93

Active participation required

- Physicians
- NNP's
- Nurses
- Respiratory Therapists

Education

- Dr. Goldsmith will meet with the NNP's, Nurses, and Respiratory therapists to educate them on the relationship between oxygen and ROP
- Flip chart
- Bedside education by the VO Respiratory group
- Introduction of the contract to the NICU employees.

Statement of Understanding and Agreement

- Each NICU staff member will be expected to sign a contract with the unit. It outlines the policy, the reason for it , and at the end, each will sign stating that they have read the information, understand it, and agree to comply with the plan.

How will we monitor our progress?

- At risk infants will be identified on admit, an order written, and their bed labeled with an OWL ICON.
- Once a shift the Charge nurse will walk through the unit at a previously undetermined time and document the actual saturation reading on each at risk infant
- If the infant is not within parameters she will document why
- The data will be collected and compliance reported to the NICU staff weekly.

Compliance?

- Saturations within the desired range-initiated in the delivery room
- Minimize abrupt Fio2 changes
- Prevent large swings in the O2 saturations
- Avoid periods of O2 saturation greater than 95%.

Goal

- Compliance at least 80% of the time.

How long do we follow them?

- Saturations will be documented each shift as long as the infant is oxygen or ventilator dependent, and weighs 500-1500 gms.
- After 1500 gms we will continue to monitor the infant for ROP, need for surgery, time on ventilator, time in oxygen, and length of stay.

After we reach 80% compliance

- We start collecting data on all of our long term goals
- Each year we will compare them to our baseline year.

Saturation Parameters will vary in other groups

- PPHN
- ECMO
- CDH
- Term infants

- The NNP's will order specific oxygen saturation parameters for each infant
- If the infant is an OWL candidate an order will be written to initiate this protocol, but remember to initiate saturation targeting at delivery if the baby is 1500gms or less.

Chow study

Results:

- Decreased ROP 3 and 4 from 12.5% (1997) to 2.5% (2001)
- Decrease need for laser surgery from 4.5% (1997) to 0 in 1999-2001.
- Compared results to Vermont Oxford Network data(430 NICU's)

- The following slide shows the studies results compared to VON data. It compares the rate of Stage 3 and 4 ROP.

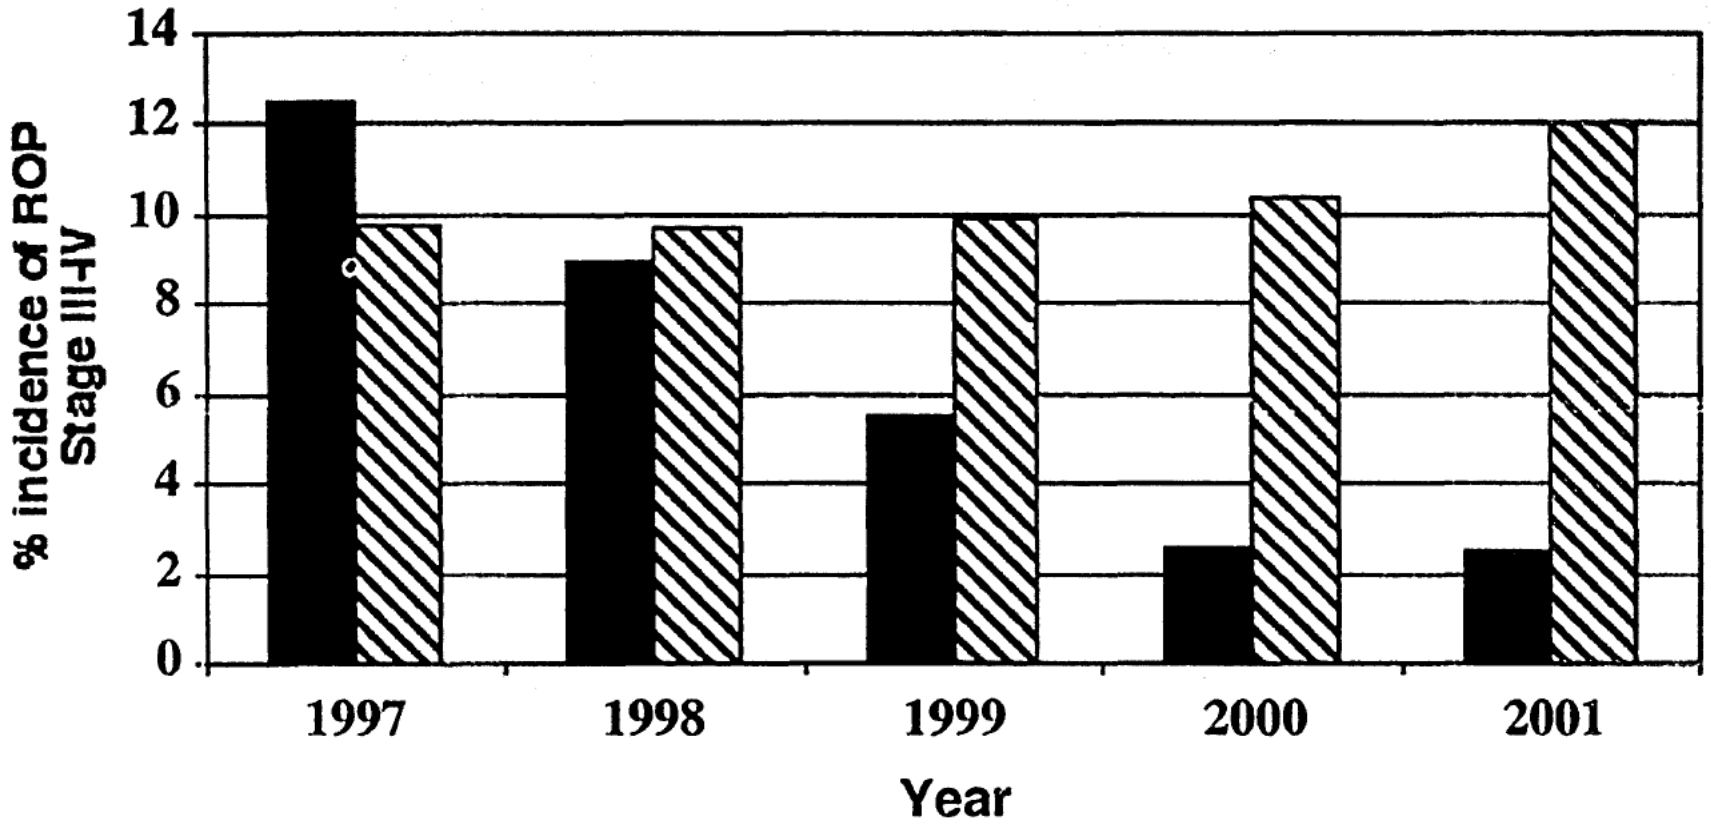

Fig 2. Incidence of ROP stages 3 to 4 for infants with birth weight of 500 to 1500 g at CSMC (■) and VON (▨) for the years 1997 to 2001. (Rates are calculated as described in "Methods.")

- The next slide shows the same comparison but of Lazer/Cryosurgery.

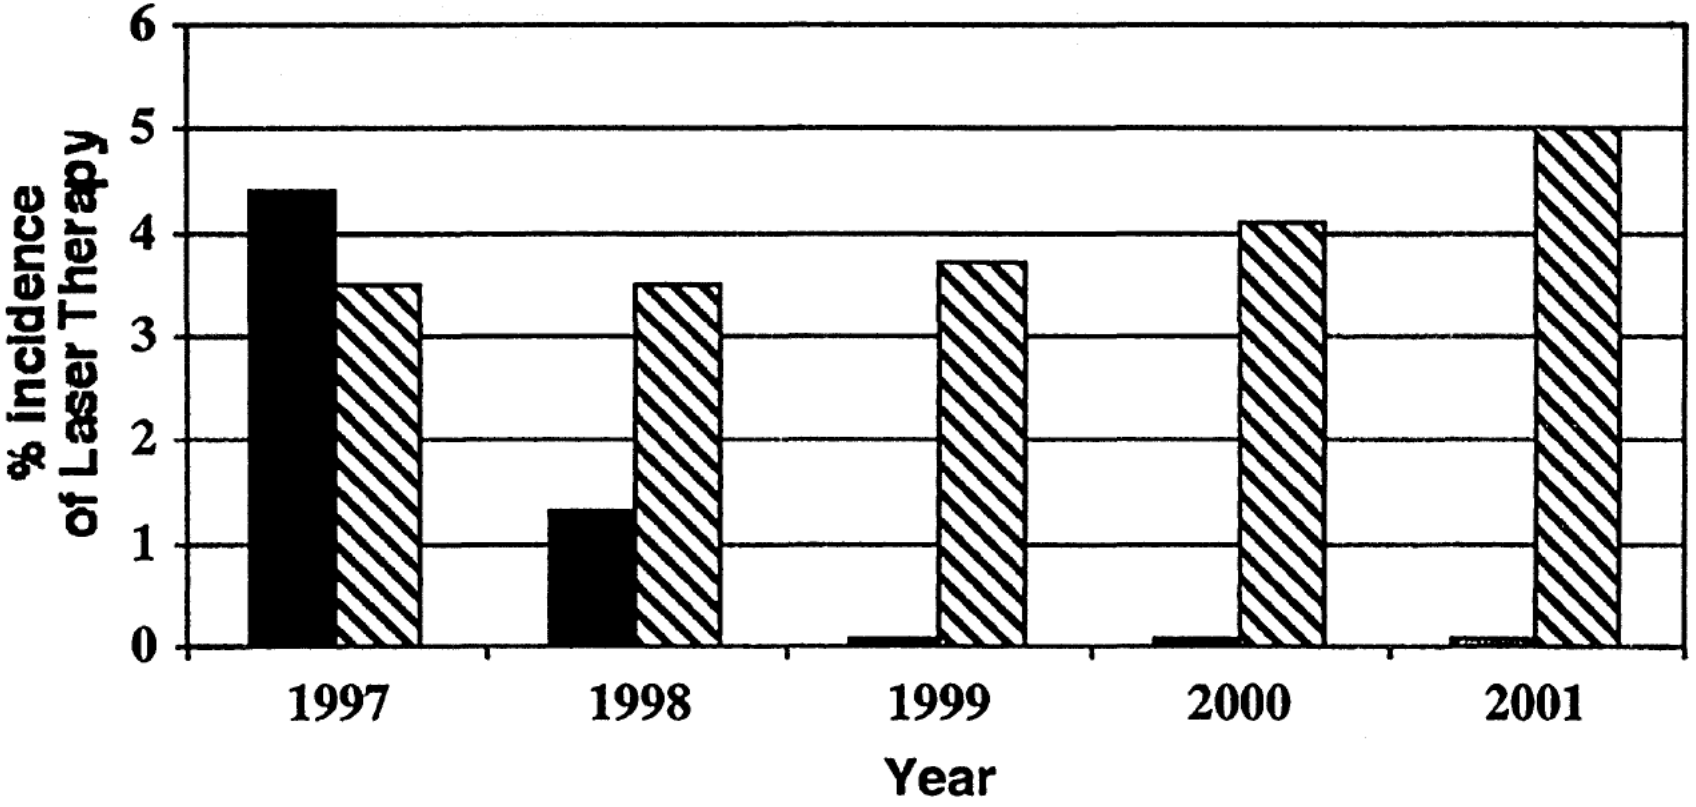

Fig 5. Incidence of ROP laser therapy for infants with birth weight of 500 to 1500 g and born at CSMC (■) and in the VON (▨) for 1997 to 2001.

What did we find at OCF?

- From 8/01 to 8/02
- 89 infants 1500gms or less
- 21 deaths/15 inborn
- 3 were short stay
- Of the remaining 65, 16 required interventional surgery (24.6%)
- 4 had stage 3 or 4 disease and did not require surgery
- 10 went home on O2(one is still here)
- 4 of those 10 required interventional surgery

OCF compared to VON

- Our ROP Lazer/Cryo surgery rate for the year 01-02 was 24.6% as compared to the national average of 5%.
- We have a lot of work to do to improve these numbers which in turn improves the eye sight of the infants that we care for.

Evidence

4 separate oxygen targeting studies have been completed to date. All 4 showed decreases in the degree of ROP as well as almost eliminating the need for interventional surgery.

What do we do?

- We can be excited about the possibility of what we can do for our patients by intervening when needed to keep their oxygen saturations at levels that minimize their risk of ROP.

The CONTRACT

- This is an explanation of what we are targeting, when to make changes and when to notify the MD/NNP of significant changes in the need for O2.
- It is an **NICU policy**.

Management of Oxygen Concentrations and Oxygen Saturations in the VLBW Infant In the OCF NICU

OBJECTIVE: To avoid hyperoxia and high/low swings in oxygen saturations in the Very Low Birth Weight (VLBW) infant. (<1500g)

1. Initiate the protocol with the admission of each infant weighing 1500 gms or less.
2. No VLBW infant will be subject at any time to repeated swings in the amount of O2 being delivered in response to the saturation readings outside the acceptable range.

STATEMENTS OF PRACTICE:

a. Oxygen should be used as a drug with potentially toxic side effects. Too much can be as damaging as too little. There is no evidence that VLBW infants need saturations in the 95-100% range and these levels are potentially dangerous. It is also significant that repeatedly alternating episodes of hypoxia and hyperoxia can cause significant alterations in the vascular tone of VLBW infants

b. Saturation alarms: be sure to make the appropriate response in dealing with an alarm
- Is the pulse wave appropriate?
- Is there artifact interference?
- Assess the infant's respiratory effort and heart rate.
- How low and how long? Has the saturation been down low enough for long enough to warrant an increase in Fio2

c. Alarm settings: The alarms should be set at 80-95. They should be changed only with an order. The alarms should not be disabled at any time

d. Weaning FiO2 and oxygen saturation levels:
- Wean by 2-5% at a time if the saturation is on the high side. (>93%) Return to baseline within 10 minutes.
- Weaning should be done as fast as necessary to avoid extended periods of Hyperoxia. (But not faster than 2-5% at a time)
- Avoid weaning in increments >5% at a time; this could result in hypoxia, which would then lead to increasing the FiO2 again.

e. Increasing the FiO2:
- When an increase is needed in the FiO2, the person making the change should stay with the infant until it has reached a stable saturation level.
- An MD/NNP must be notified for any sustained need for an increase in FiO2 greater than 10% from the previously stable FiO2.

f. During and after procedures:
- FIO2 should not be routinely increased prior to a procedure. Respond appropriately to the needs of

the infant based on the saturations as well as the length and type of procedure.

- Monitor the infant after suctioning the ETT until the baby returns to a stable baseline.
- Consider that other settings (rate, PIP, CDP) may need to be changed for a prolonged procedure.

f. Spontaneous oxygen desaturations:

- The Nurse and the Respiratory therapist should work together to assess both the infant and the ventilator and/or oxygen delivery systems.
- Decide together whether an MD/NNP needs to be notified for intervention other than increased FIO2

g. Apnea:

- Choose the appropriate response based on the exam of the infant; increased respiratory rate, increase the approved parameters, use tactile stimulation, or in severe cases manual ventilation.
- If the baby does not return to the previously stable baseline (same FIO2) within 10 minutes, the MD/NNP should be notified.

SUMMARY:

BASELINE FOR THE VLBW INFANT (birth weight <1500 g)

1. Set oxygen saturation monitor alarm limits at 80-95%.
2. Do not "TITRATE" FiO2 (risky to create extreme ups and downs in the infants saturations.) Allow baby to fluctuate within the desired saturation parameters, making small movements up and down on FiO2 as needed.
3. Based on assessment wean actively by 2-5% for saturations on the high side of parameters
4. Never increase the FiO2 without first assessing the baby.

5. If the need for increased FiO2 is sustained, the MD/NNP must be notified.
6. Document saturation levels and oxygen requirements clearly (as per unit policy)
7. When altering the oxygen being delivered stay with the infant until the saturations have stabilized within an acceptable range

Adapted form the policy prepared by Augusto Sola, MD, Published in *Pediatrics* (February 2003);111:339

Potentially Better Practice Concept: Worksheet

Topic Area: Respiratory

Potentially Better Practice: Oxygen Targeting to avoid hyperoxia in infants at risk for retinopathy of prematurity and chronic lung disease.

Rationale: Controlled reduced oxygen dosing may decrease the incidence of retinopathy of prematurity and chronic lung disease.

Classifying the strength and quality of the evidence:

1. Strong evidence from at least one systemic review of multiple well designed randomized controlled trials.
2. Evidence from a well-designed non-experimental study preferably from more than one center or research group.
3. Opinions of respected authorities, based on clinical evidence, descriptive studies or reports of expert committees.

Pertinent References:

1. The STOP-ROP Multicenter Study Group, Pediatric, 2000: 105: 295. Supplemental Therapeutic Oxygen for Prethreshold Retinopathy of Prematurity (STOP-ROP), Randomized, Controlled Trial, I Primary Outcomes
2. Horbar, Clark, and Lucey, Pediatrics: 1980:66:848: The Newborn Oxygram: Automated Processing of Transcutaneous Data
3. Long, Philip, and Lucey: Pediatrics, 1980:65:203,Excessive Handling as a Cause of Hypoxemia
4. Chow et al, Pediatrics: 2003, 111:339. Can Changes in Clinical Practice decrease the Incidence of Severe Retinopathy of Prematurity in Very Low Birth Weight Infants.
5. Tin et al, Arch Dis Child, Fetal Neonatal Ed: 2001: 84:F106. Pulse Oximetry, severe Retinopathy, and outcome at one year in babies of less than 28 weeks gestation
6. Schulze et al, J Pediatrics:1995: 126: 777. Effect of the arterial oxygenation level on cardiac output, oxygen extraction, and oxygen consumption in low birth weight infants receiving mechanical ventilation.

7. Askie et al, Pediatric Research: 2002; 51:378A The effect of differing oxygen saturation targeting ranges on long term growth and development of extremely preterm, oxygen dependent infants: The Boost Trial
8. ReLi Study: Unpublished work product of NICUQ 2000 ReLi Group.

Potential Benefits:

1. Reduction in ROP rates (measured by decreased Stage 3 and 4 disease, as well as decreased need for interventional surgery).
2. Reduction in Chronic lung disease (measured by decreased need for oxygen at 36 weeks PMA, decreased length of days in oxygen, and decreased length of hospital stay).

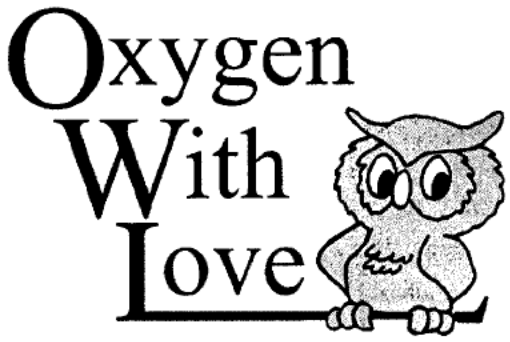
Potential Risks and costs:

1. Unrecognized system problems related to change in practice
   - Resistance to change-large effect on general practice techniques
   - Need for education on the varying requirements of Oxygen levels for the varying types of infants
   - False positives and response times
   - O2 Saturation Monitoring devices
2. Potential for poor growth, feeding intolerance, decreased physical activity, and decreased alertness in infants with established lung disease
3. Change in sleep patterns
3. Increased frequency of alarm rates leading to decreased compliance from staff.
4. No increase in costs, monitoring system already in place.
5. Increased mortality or morbidity from hypoxia.

How does the concept become operational?:

- Review the important parameters for oxygen saturation management for at risk babies.
- Develop goals for parameters of oxygen saturations.

- Establish an ICON to identify each infant at risk (**O**xygen **W**ith **L**ove)



- Develop a tool for monitoring compliance
- Educate the staff
- Do random walk through every 12 hours and document saturation level on at risk infants.
- Initiate plan and study compliance rate on a monthly basis

Rose

I am very worried that such delays will have a large negative impact on SUPPORT, and also for all the other similar trials.

Can we try a videoconference, combined with a Webcast or similar technology?

Thanks for considering this.

Neil

As you know, Dr. Avery, Chair of the DSMC has requested a face-to-face meeting with the members to discuss the SUPPORT Trial. Therefore, we are inquiring about your availability to attend a one day meeting in DC. The dates being considered are January 9th, 10th, 11th, 20th or sometime the week of the 23rd - 27th.

Thank you very much for your time.

Cathy
I received this email this am. This is in respect to the SUPPORT Trial being stopped and an email that was cc'd to Cynthia Cole. I spoke to Barbara about it because she is the PI at the Emory site (not because she is the chairman). I would like to discuss this with you this afternoon if you have time. I will re-forward you the email in question.
Sorry for all the trouble!
Rose

Subject: Information and communication

Dear Dr Higgins,
On or about 12/8 Dr Stoll sent me a copy of an e-mail written by me, which she said made it to NIH and was forwarded to her.
I replied the same day to Dr Stoll in detail and I am not sure if you saw my response.
In any case, it is distressing to me that someone will take time to take my e-mail out of context and forward it to NIH, who knows with what objective/purpose. Actually, this procedure may fall outside of accepted ethical behavior and may be a violation of privacy (as written nowadays at the bottom of many e-mails, ..."
>This message is for the designated recipient only and may contain
>privileged or confidential information.
.....")
Be this as it may, in order to avoid misunderstandings or miscommunication I would like to respectfully request that if you have any questions about what I say or write you please contact me directly and not through the Department Chair. I will be more than willing to answer openly and directly any questions you may have.
Many Thanks
Sincerely
Augusto Sola

Subject: RE: DSMC minutes

We usually dont share unedited DSMC minutes with the sites. However, for the SUPPORT study, if this is for documents that we have already sent to the PIs and coordinators, then I dont see any harm in putting them up on the private section of the website.

Subject: Re: SUPPORT TRIAL
Date: Monday, December 12, 2005 4:12:14 PM

Bloody hell – what is so complex! I thought the responses were rather clear. Do they need a consultant there to sort out the problems –I suggest that the PI be present to answer questions/misconceptions. The NICHD DMSC's have been overenthusiastic about stopping trials.

The slides are pretty as well as informative
I would add to the slide that the Case Infants had similar criteria but were not randomized for various reasons - mainly parental refusal I believe but Michele can correct me.

Median SpO2 in healthy preterm infants = 97% (Ng et al Arch Dis Child 1998;79:F64) - I presume this is in room air and would so state.

Thanks
Av

Subject: Data Monitoring Committee

Dear Dr. Higgins,

This e-mail is to notify you of my resignation as a member of the Data Safety Monitoring Committee for the NICHD NICU Trials.

I have been a member of the committee for more than ten years. As the only biostatistician on the committee in recent years, I have had a number of concerns about changes in the operating procedures for the committee in recent years and whether we are able to perform our role appropriately and effectively. It has been several years since we have had a face to face meeting although there have been a number of changes in the committee members. Teleconference meetings have not incorporated or facilitated in depth discussions important for the committee functioning, particularly in reviewing the protocols and consent forms for matters relating to the protection of safety of the subjects, recommendations for frequency and information to be provided for interim monitoring, and other major aspects of fulfilling our charge. It is also my understanding that we are advisory to the institute which may choose to accept or decline our recommendations.

The response to our recommendations regarding the SUPPORT Trial exemplify some of the issues that concern me. I will be happy to discuss my concerns with you in more detail if you wish, but do not have time this morning to do so.

With respect to the SUPPORT Trial, it is unfortunate that there will be no independent DMC biostatistician participating in the conference call since our initial recommendations and the information provided clearly involve important statistical considerations. When the conference call was scheduled, I indicated that I was not available until the latter part of the week. I am currently attending the meeting of the American Public Health Association in Philadelphia, with a prior commitment to a session at the same time that the conference call is scheduled. When I questioned the scheduling, I was told that I could read the information and provide any comments to the chair in advance. Although I have reviewed the materials and have some initial impressions, major biostatistical issues can only be addressed appropriately through participation in the meeting in collaboration with other members' expertise. I encourage that an independent biostatistician be found for the committee as soon as possible and that biostatistical expertise be fully integrated in review and decisions. During the early years of my participation, we had two biostatisticians on the committee, which provided an opportunity for back-up should one of us be unavailable; perhaps the committee could include two biostatisticians.

Dr. Avery has always provided very excellent and capable leadership of the DMC. It has been my pleasure to serve on the committee during his tenure as chair.

Please do not hesitate to contact me if you have any questions or would like to discuss the reasons for my resignation further.

Sincerely,

Carol Redmond

Attached for your review is a PowerPoint presentation that was prepared by Dr. Neil Finer. We are hoping that you will have an opportunity to review this presentation prior to the call tomorrow.

Thank you for all of your help in reviewing this Support Trial material. <<SUPPORT Trial Final DSMC Response - Dec 121.ppt>>

Betty

Dear DSMC Members,
The DSMC conference call, to discuss the SUPPORT study, has been scheduled for Tuesday, December 13, at 2:00pm EST. To join this call please **dial the toll free number 888-396(b) (6) and enter the numeric Passcode (b) (6) (# when prompted). (The USA Toll Number is +1-210-839-(b) (6).** The leader of the call is Dr. Abhik Das. The agenda, list of participants and material to be discussed will be sent by Fed-Ex on December 6th. Please let me know if you do not receive this material.

Thank you.
Betty

SUPPORT Trial
Response to the DSMC

Neil Finer – Principal Investigator

For the SUPPORT Subcommittee and the Steering Committee

NICHD Neonatal Research Network

December 11 2005

Report of the DSMC Nov 2005

The DSMC expressed 2 concerns:

1. There is a significant safety and exposure issue for the infants in the high saturation treatment group because an unacceptably high proportion of time was spent by these study subjects in the >95% range

Report of the DSMC Nov 2005

2. There is a futility concern for this arm of the trial in that there does not appear to be substantial separation between the two high and low saturation treatment groups, and the babies are not being kept in the target range the appropriate amount of time in order to meaningfully test the oxygen saturation intervention as originally designed.

Evidence for Current SpO2 Ranges

- **SUPPORT Trial alarm limits were chosen as those most currently utilized within the Network and consistent with current evidence.**
- **To maintain PaO2 between 40 and 90mmHg would require SpO2 alarms of 92.5% to 95% (Paky et al Acta Paediatr. 1995 Jun; 84(6):613-6.)**

Evidence for Current SpO2 Ranges

- **No current prospective studies that have evaluated actual durations of time at various SpO2 levels**
- **Median SpO2 in healthy preterm infants in room air = 97% (Ng et al Arch Dis Child 1998;79:F64)**
- **All published studies reported target ranges ie lower vs higher using High SpO2 limits -92% vs 95% for populations but did not present any data as to how well these target were adhered to.**
- **Sun et al compared units with upper limits of >95% with those of ≤ 95% (Ped Res 2002, 51:350A)**

Evidence for Current SpO2 Ranges

- **Tin et al reported units by the limits they set without any individual patient data (Tin et al Arch Dis Child 2001;84:F106)**
- **Another survey compared SpO2 limits > 98% with ≤ 98%, and early limits – first 2 weeks- of > 92% vs < 92% (Anderson Ped Res 2002;51:367A)**
- **Chow et al reported on a change of practice with lowering of the SpO2 limit and other changes – They did not provide any actual SpO2 data (Chow et al, Pediatr 2003;111:339)**
- **All of these studies suggested that lower SpO2 limits were associated with less ROP.**

Evidence for Current SpO2 Ranges

- **Prior to the initiation of SUPPORT – there were no data indicating the actual percent of time ELBW infants spend at different SpO2 values or ranges**
- **The design of the trial using oximeter downloads was unique and will provide this information based on a large prospective cohort**
- **This trial was also unique in collecting this data from 2 hours of age in acutely unstable ELBW infants until they are out of oxygen for 3 days.**

Response to DSMC

Safety Issue of SpO2>95%

Concern regarding safety issue of duration of SpO2 > 95%

- ✓ **The current best data utilizing actual oximeter data is from Hagadorn et al (PAS 2004 Abstract: Late Breaker)**
- ✓ **Evaluated 78 ELBW infants for 70 hours per week for the first 4 weeks of life**
- ✓ **Lower and upper SpO2 limits were 83% -92% and 92%-98%**
- ✓ **Median SpO2 = 95%**
- ✓ **Medians from SUPPORT Oximeter groups – 92% and 94%, and for infants only in oxygen for the entire day the medians are 91% vs 93%.**

Response to DSMC:
Safety Issue of SpO2>95%

- STOP-ROP high treatment infants spent 97% of time > 95%
- Case Western a current NRN Center – Current data from SUPPORT type ELBW infants – SpO2 > 95% for > 50% time
- SUPPORT Infants on room air – SpO2 > 95% from 46% to 69% of time

Response to DSMC:
Safety Issue of SpO2>95%

- **Additional analyses evaluated the duration of time at SpO2 values of 98%, 99% and 100% as these may represent very high PaO2 values**
- **Infants in SUPPORT in ROOM Air spend more time at these values than infants receiving oxygen – 32% - 38% versus 5%-6%**

SUPPORT Trial Actual Results

91% - 95% Room Air 85% - 89%

	%	Cum %	%	Cum%
98%	15.49%	77.15	13.65%	81.42
99%	12.94%	90.09	10.37%	91.79
100%%	9.91%	100.00	8.21%	100.00
Total	38.3%		32.2%	

91% - 95% Oxygen 85% - 89%

98%	3.51%	96.90	2.66%	97.23
99%	1.90%	98.80	1.60%	98.83
100%	1.20%	100.00	1.17%	100.00
Total	6.6%		5.4%	

Response to DSMC: Safety Issue of SpO2>95%

- **The actual algorithm for conversion of displayed versus actual values results in inability to create a whole value for each displayed value.**
- **The data evaluated by the DSMC had an overestimation of durations > 95% in view of the data assigned conversion values of decimal values at 95% and considered to be > 95%**
- **This represented greater than 6% of the initial calculated durations > 95% for the 91%-95% group**

Response to DSMC: Safety Issue of SpO2>95%

- **In an effort to provide better information regarding both high and low SpO2 values and avoid the problem with the re-conversion algorithm, we asked for analyses for durations > 96% and < 84% as these are values which do not require conversion and are always unaltered.**

Response to DSMC: Safety Issue of SpO2>95%

- ✘ Any calculations which incorrectly assigned infants on room air to be analyzed as receiving Oxygen would overestimate the durations > 95%
- ✘ Our data forms only reported 3 FiO2 data points daily for the first 14 days and then only a single daily value thereafter.
- ✘ Thus we were using oximeter data and assigning it based on these data points to determine the true days in oxygen
- ✓ Reanalysis based on assigning the infant to oxygen only if all 3 points for the day had an FiO2 > .21 showed markedly lower durations of SpO2 > 95% and greater than 96%

Response to DSMC: Safety Issue of SpO2>95%

Percent of time of spent at SpO2 < 84% and > 96% (RTI Analyses In Oxygen, Dec 2, 2005)

Range Assigned	High target (91-95)	Low target (85-89)
< 84%	8.30%	14.05%
> 96%	21.45%	15.47%

Response to DSMC:
Futility regarding Separation of Oximeter Groups

- **Further analyses including only infants on Oxygen at all 3 data points for a given day**

(RTI Analyses In Oxygen all 3 Points, Dec 5, 2005)

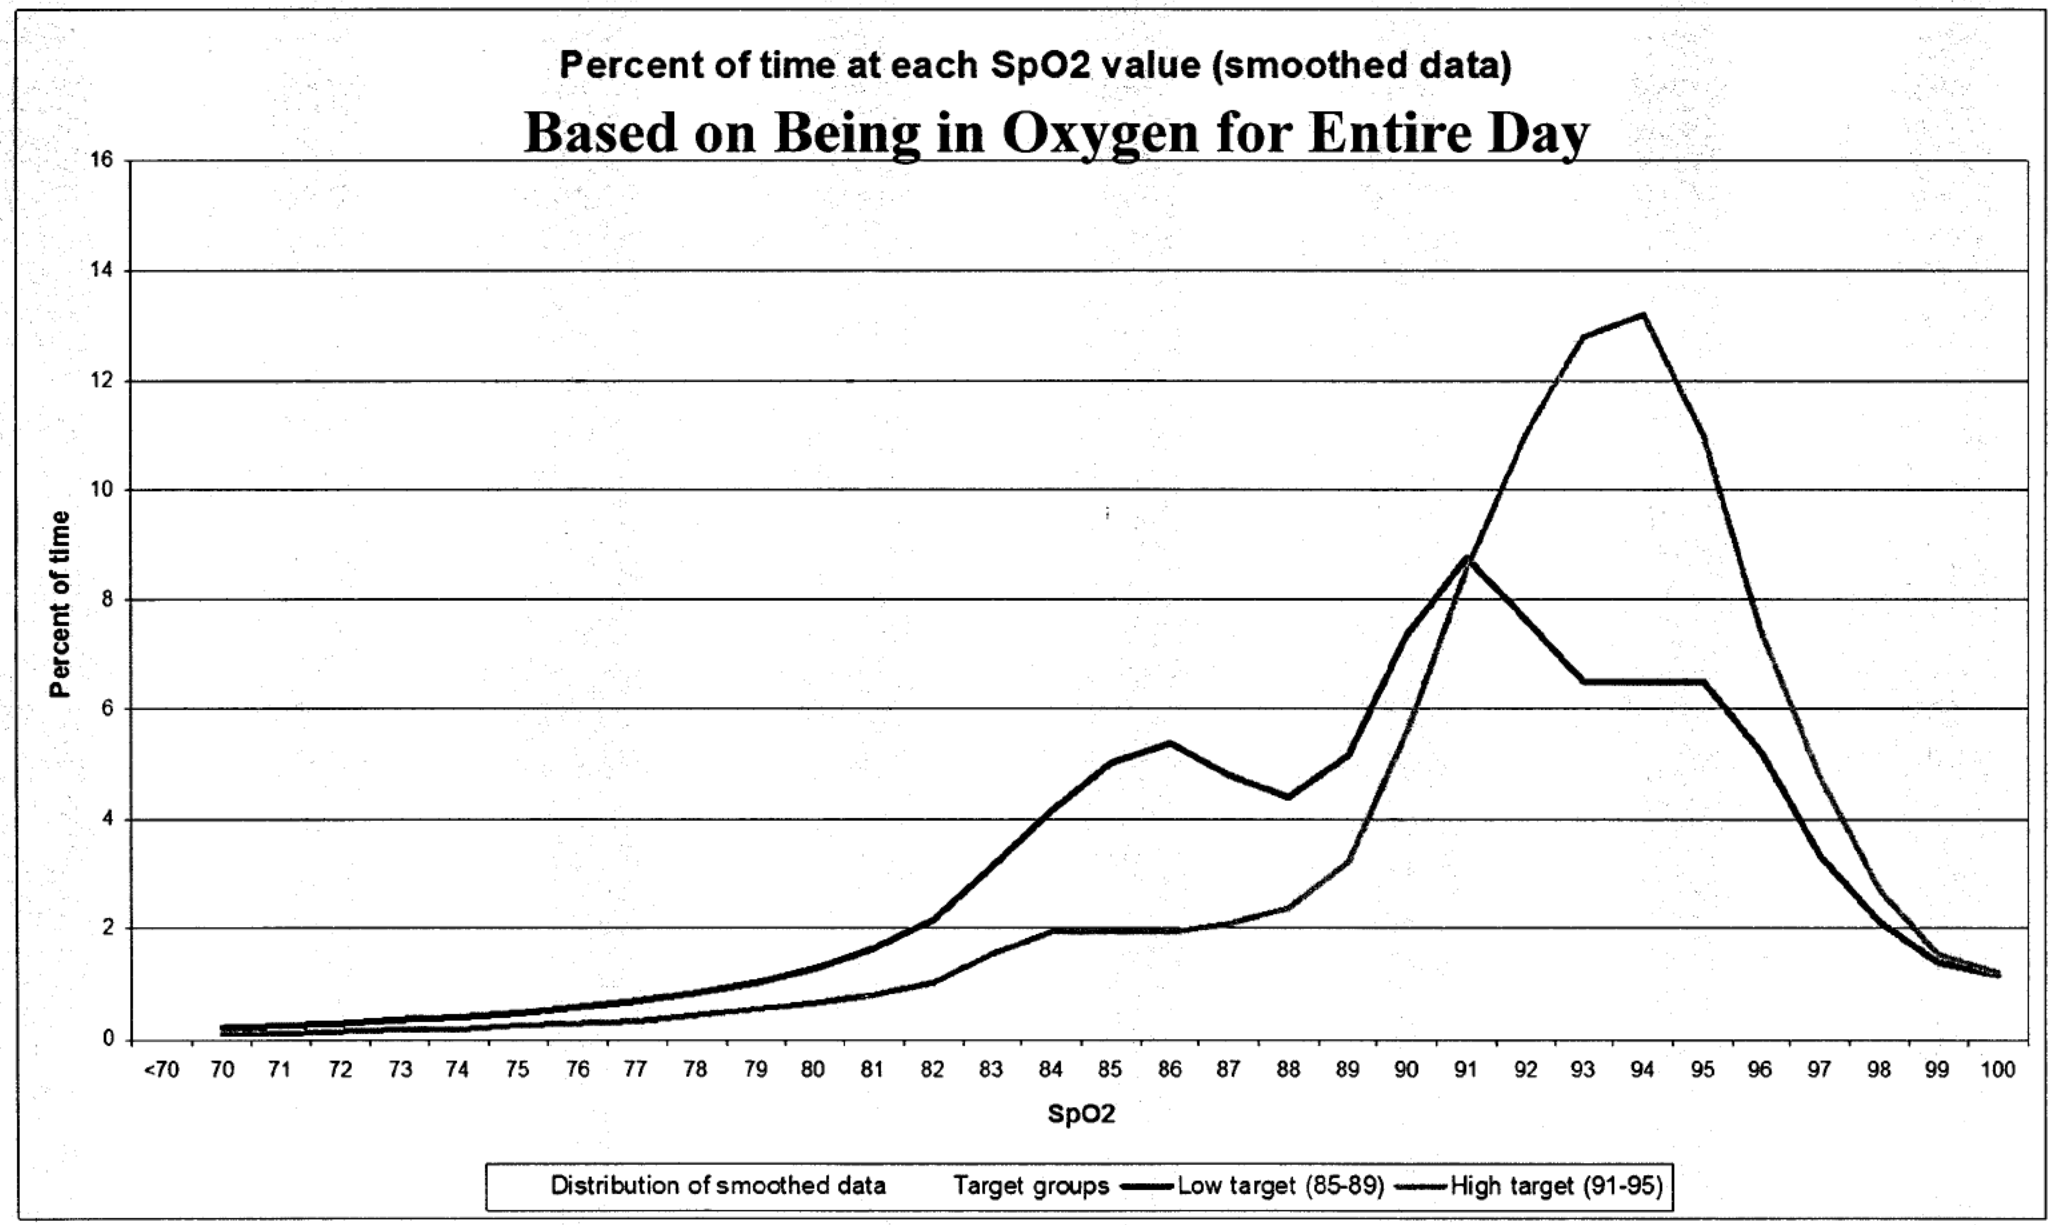
Range Assigned	High target (91-95)	Low target (85-89)
< 84%	6.40%	13.3%
> 96%	12.5%	9.39%

Response to DSMC: Safety Issue of SpO2>95%

- **We believe that neither oximeter group in the SUPPORT trial is being exposed to excessive durations of SpO2 > 95% based on all currently available information and the actual SUPPORT Trial Data analyzed to date.**
- **Current analyses demonstrate that the highest duration of SpO2 > 95% was 22.9%, and > 96% was 12.5% using only infants known to be in oxygen for all 3 daily data points in the first 14 days of life.**
- **These values are previously unreported for such a population, and significantly less than the original data reviewed by the DSMC.**

Response to DSMC:
Futility regarding Separation of Oximeter Groups

- **An evaluation of the oximeter group data has revealed that there is a difference in the Mean - 90% vs 92% and Median values for the 2 groups – 92% vs 94%**
- **The Median SpO2s obtained using only days that were in oxygen at all 3 data points were 91% vs 93%**
- **These additional analyses have demonstrated that the cumulative time spent with an SpO2 of 90% or less is 22.80% (91% - 95%) versus 47.6% (85% - 89%) for a > 24% absolute difference between the groups.**



Response to DSMC:
Futility regarding Separation of Oximeter Groups

- **We examined the actual FiO2 requirement of the infants in the Oximeter arms.**
- **If the algorithms were working as intended, then there should be a difference in the FiO2 requirement between the groups**

Response to DSMC:
Futility regarding Separation of Oximeter Groups

- **The Actual time spent in Room Air during the first 14 days of life was 26.6% versus 35.5% for the 91%-95% group compared to the 85%-89% group.**
- **These differences persisted for data beyond 14 days**
- **The 2 groups remained separated by at least 3% duration for FiO2s of $\leq$ 50%**

Response to DSMC:
Futility regarding Separation of Oximeter Groups

- **The time in actual Target using only days when infants are in oxygen for all 3 data points**

91-95% = 55% 85% - 89% = 24.6%

Response to DSMC:
Futility regarding Separation of Oximeter Groups

- **The 91% - 95% are more in target because their alarm sounds when they reach 95%**

✘ **The 85% - 89% are less time in target because when their SpO2 is > 89% (a reading of 93%) there is no alarm. The alarm only sounds at a reading of 95%**

✓ **We believe that we can improve this time in range by lowering the high alarm to 94%**

Response to DSMC:
Futility regarding Separation of Oximeter Groups

- **It is uncertain what duration of differences in either SpO2 of FiO2 will be associated with different short and long term outcomes, but we are achieving some separation in both to the present.**
- **We believe that greater separation is possible and desirable and have made a number of recommendations to ensure that this will occur.**

Response to DSMC:
Suggestions for Increasing Separation of Oximeter Groups

1. **Set high SpO2 limit – alarm to 94%. This will reduce the duration of SpO2 values > 95% for both groups, and should increase the time both groups spend in the narrow target range.**
2. **Require documentation that the oximeters alarm limits are set and functional as per protocol every 4-6 hours**
3. **Change our data collection for FiO2 to ensure that subsequent interval reports more accurately reflect saturations measured while on oxygen therapy and exclude saturations of infants in room air**

Response to DSMC:

Suggestions for Increasing Separation of Oximeter Groups

4. Further training and in-service at all the sites to stress the importance of keeping the SpO2 alarms functional and at the limits of 85% and 94%. We will use the OWL (Oxygen with Love Program) developed at Oschner.
5. Develop guidelines for managing desaturations such that the increase in oxygen is proportional to the desaturation
6. Place bedside cards to indicate the desired target range

Response to DSMC:

Suggestions for Increasing Separation of Oximeter Groups

7. Initiate compliance monitoring visits coordinated by RTI to visit random sites
8. Reanalyze group differences after an additional 100-150 infants have been enrolled.
9. Utilize only actual SpO2 values for assessment of safety in subsequent analyses ie; SpO2 < 84% and > 96%, and analyze only actual time in oxygen.

Response to DSMC

- **The SUPPORT Trial Committee and the Network Steering Committee appreciate the diligence and suggestions of the Data Safety Monitoring Committee**
- **We trust that our response and suggestions to improve the SUPPORT Trial are found acceptable and that we may be allowed to continue this important trial.**

Hi Betty
Av found another typo, and then so did I.
They are fixed in this version labeled Dec 12
Please circulate to the DSMC.
Many thanks
Neil

Hi Betty and Rose and Everyone

I am sorry to keep modifying our response but I want our presentation to be tight, factual, and convincing. I would like this PowerPoint presentation to be sent to the DSMC for the call on Tuesday. I will use this in the time allocated to me – I can do this in 15 minutes leaving lots of time for questions. If you feel that any of the additional analyses should also be sent to them, these are attached.

Please let me know if you find any errors – I have reviewed it so often it is all beginning to blur!

Be well
Neil

SUPPORT Trial
Response to the DSMC

Neil Finer – Principal Investigator

For the SUPPORT Subcommittee and the Steering Committee

NICHD Neonatal Research Network

December 11 2005

Report of the DSMC Nov 2005

The DSMC expressed 2 concerns:

1. There is a significant safety and exposure issue for the infants in the high saturation treatment group because an unacceptably high proportion of time was spent by these study subjects in the >95% range

Report of the DSMC Nov 2005

2. There is a futility concern for this arm of the trial in that there does not appear to be substantial separation between the two high and low saturation treatment groups, and the babies are not being kept in the target range the appropriate amount of time in order to meaningfully test the oxygen saturation intervention as originally designed.

Evidence for Current SpO2 Ranges

- **SUPPORT Trial alarm limits were chosen as those most currently utilized within the Network and consistent with current evidence.**
- **To maintain PaO2 between 40 and 90mmHg would require SpO2 alarms of 92.5% to 95% (Paky et al Acta Paediatr. 1995 Jun; 84(6):613-6.)**

Evidence for Current SpO2 Ranges

- **No current prospective studies that have evaluated actual durations of time at various SpO2 levels**
- **Median SpO2 in healthy preterm infants in room air = 97% (Ng et al Arch Dis Child 1998;79:F64)**
- **All published studies reported target ranges ie lower vs higher using High SpO2 limits -92% vs 95% for populations but did not present any data as to how well these target were adhered to.**
- **Sun et al compared units with upper limits of >95% with those of ≤ 95% (Ped Res 2002, 51:350A)**

Evidence for Current SpO2 Ranges

- **Tin et al reported units by the limits they set without any individual patient data (Tin et al Arch Dis Child 2001;84:F106)**
- **Another survey compared SpO2 limits > 98% with ≤ 98%, and early limits – first 2 weeks- of > 92% vs < 92% (Anderson Ped Res 2002;51:367A)**
- **Chow et al reported on a change of practice with lowering of the SpO2 limit and other changes – They did not provide any actual SpO2 data (Chow et al, Pediatr 2003;111:339)**
- **All of these studies suggested that lower SpO2 limits were associated with less ROP.**

Evidence for Current SpO2 Ranges

- **Prior to the initiation of SUPPORT – there were no data indicating the actual percent of time ELBW infants spend at different SpO2 values or ranges**
- **The design of the trial using oximeter downloads was unique and will provide this information based on a large prospective cohort**
- **This trial was also unique in collecting this data from 2 hours of age in acutely unstable ELBW infants until they are out of oxygen for 3 days.**

Response to DSMC

Safety Issue of SpO2>95%

Concern regarding safety issue of duration of SpO2 > 95%

- ✓ **The current best data utilizing actual oximeter data is from Hagadorn et al (PAS 2004 Abstract: Late Breaker)**
- ✓ **Evaluated 78 ELBW infants for 70 hours per week for the first 4 weeks of life**
- ✓ **Lower and upper SpO2 limits were 83% -92% and 92%-98%**

SUPPORT Trial
Response to the DSMC

Neil Finer – Principal Investigator

For the SUPPORT Subcommittee and the Steering Committee

NICHD Neonatal Research Network

December 11 2005

Report of the DSMC Nov 2005

The DSMC expressed 2 concerns:

1. **There is a significant safety and exposure issue for the infants in the high saturation treatment group because an unacceptably high proportion of time was spent by these study subjects in the >95% range**

Report of the DSMC Nov 2005

2. There is a futility concern for this arm of the trial in that there does not appear to be substantial separation between the two high and low saturation treatment groups, and the babies are not being kept in the target range the appropriate amount of time in order to meaningfully test the oxygen saturation intervention as originally designed.

Evidence for Current SpO2 Ranges

- **SUPPORT Trial alarm limits were chosen as those most currently utilized within the Network and consistent with current evidence.**
- **To maintain PaO2 between 40 and 90mmHg would require SpO2 alarms of 92.5% to 95% (Paky et al Acta Paediatr. 1995 Jun; 84(6):613-6.)**

Evidence for Current SpO2 Ranges

- **No current prospective studies that have evaluated actual durations of time at various SpO2 levels**
- **Median SpO2 in healthy preterm infants in room air = 97% (Ng et al Arch Dis Child 1998;79:F64)**
- **All published studies reported target ranges ie lower vs higher using High SpO2 limits -92% vs 95% for populations but did not present any data as to how well these target were adhered to.**
- **Sun et al compared units with upper limits of >95% with those of $\leq$ 95% (Ped Res 2002, 51:350A)**

Evidence for Current SpO2 Ranges

- **Tin et al reported units by the limits they set without any individual patient data (Tin et al Arch Dis Child 2001;84:F106)**
- **Another survey compared SpO2 limits > 98% with ≤ 98%, and early limits – first 2 weeks- of > 92% vs < 92% (Anderson Ped Res 2002;51:367A)**
- **Chow et al reported on a change of practice with lowering of the SpO2 limit and other changes – They did not provide any actual SpO2 data (Chow et al, Pediatr 2003;111:339)**
- **All of these studies suggested that lower SpO2 limits were associated with less ROP.**

Evidence for Current SpO2 Ranges

- **Prior to the initiation of SUPPORT – there were no data indicating the actual percent of time ELBW infants spend at different SpO2 values or ranges**
- **The design of the trial using oximeter downloads was unique and will provide this information based on a large prospective cohort**
- **This trial was also unique in collecting this data from 2 hours of age in acutely unstable ELBW infants until there are out of oxygen**

Response to DSMC

Safety Issue of SpO2>95%

Concern regarding safety issue of duration of SpO2 > 95%

- ✓ **The current best data utilizing actual oximeter data is from Hagadorn et al (PAS 2004 Abstract: Late Breaker)**
- ✓ **Evaluated 78 ELBW infants for 70 hours per week for the first 4 weeks of life**
- ✓ **Lower and upper SpO2 limits were 83% -92% and 92%-98%**
- ✓ **Median SpO2 = 95%**
- ✓ **Medians from SUPPORT Oximeter groups – 92% and 94%, and for infants only in oxygen for the entire day the medians are 91% vs 93%.**

Response to DSMC:
Safety Issue of SpO2>95%

- STOP-ROP high treatment infants spent 97% of time > 95%
- Case Western a current NRN Center – Current data from SUPPORT type ELBW infants – SpO2 > 95% for > 50% time
- SUPPORT Infants on room air – SpO2 > 95% from 46% to 69% of time

Response to DSMC:
Safety Issue of SpO2>95%

- **Additional analyses evaluated the duration of time at SpO2 values of 98%, 99% and 100% as these may represent very high PaO2 values**
- **Infants in SUPPORT in ROOM Air spend more time at these values than infants receiving oxygen – 32% - 38% versus 5%-6%**

SUPPORT Trial Actual Results

91% - 95% Room Air 85% - 89%

	%	Cum %	%	Cum%
98%	15.49%	77.15	13.65%	81.42
99%	12.94%	90.09	10.37%	91.79
100%%	9.91%	100.00	8.21%	100.00
Total	**38.3%**		**32.2%**	

91% - 95% Oxygen 85% - 89%

98%	3.51%	96.90	2.66%	97.23
99%	1.90%	98.80	1.60%	98.83
100%	1.20%	100.00	1.17%	100.00
Total	**6.6%**		**5.4%**	

Response to DSMC: Safety Issue of SpO2>95%

- The actual algorithm for conversion of displayed versus actual values results in inability to create a whole value for each displayed value.
- The data evaluated by the DSMC had an overestimation of durations > 95% in view of the data assigned conversion values of decimal values at 95% and considered to be > 95%
- This represented greater than 6% of the initial calculated durations > 95% for the 91%-95% group

Response to DSMC: Safety Issue of SpO2>95%

- **In an effort to provide better information regarding both high and low SpO2 values and avoid the problem with the re-conversion algorithm, we asked for analyses for durations > 96% and < 84% as these are values which do not require conversion and are always unaltered.**

Response to DSMC: Safety Issue of SpO2>95%

- ✘ Any calculations which incorrectly assigned infants on room air to be analyzed as receiving Oxygen would overestimate the durations > 95%
- ✘ Our data forms only reported 3 FiO2 data points daily for the first 14 days and then only a single daily value thereafter.
- ✘ Thus we were using oximeter data and assigning it based on these data points to determine the true days in oxygen
- ✓ Reanalysis based on assigning the infant to oxygen only if all 3 points for the day had an FiO2 > .21 showed markedly lower durations of SpO2 > 95% and greater than 96%

Response to DSMC: Safety Issue of SpO2>95%

Percent of time of spent at SpO2 < 84% and > 96% (RTI Analyses In Oxygen, Dec 2, 2005)

Range Assigned	High target (91-95)	Low target (85-89)
< 84%	8.30%	14.05%
> 96%	21.45%	15.47%

Response to DSMC:
Futility regarding Separation of Oximeter Groups

- **Further analyses including only infants on Oxygen at all 3 data points for a given day**

(RTI Analyses In Oxygen all 3 Points, Dec 5, 2005)

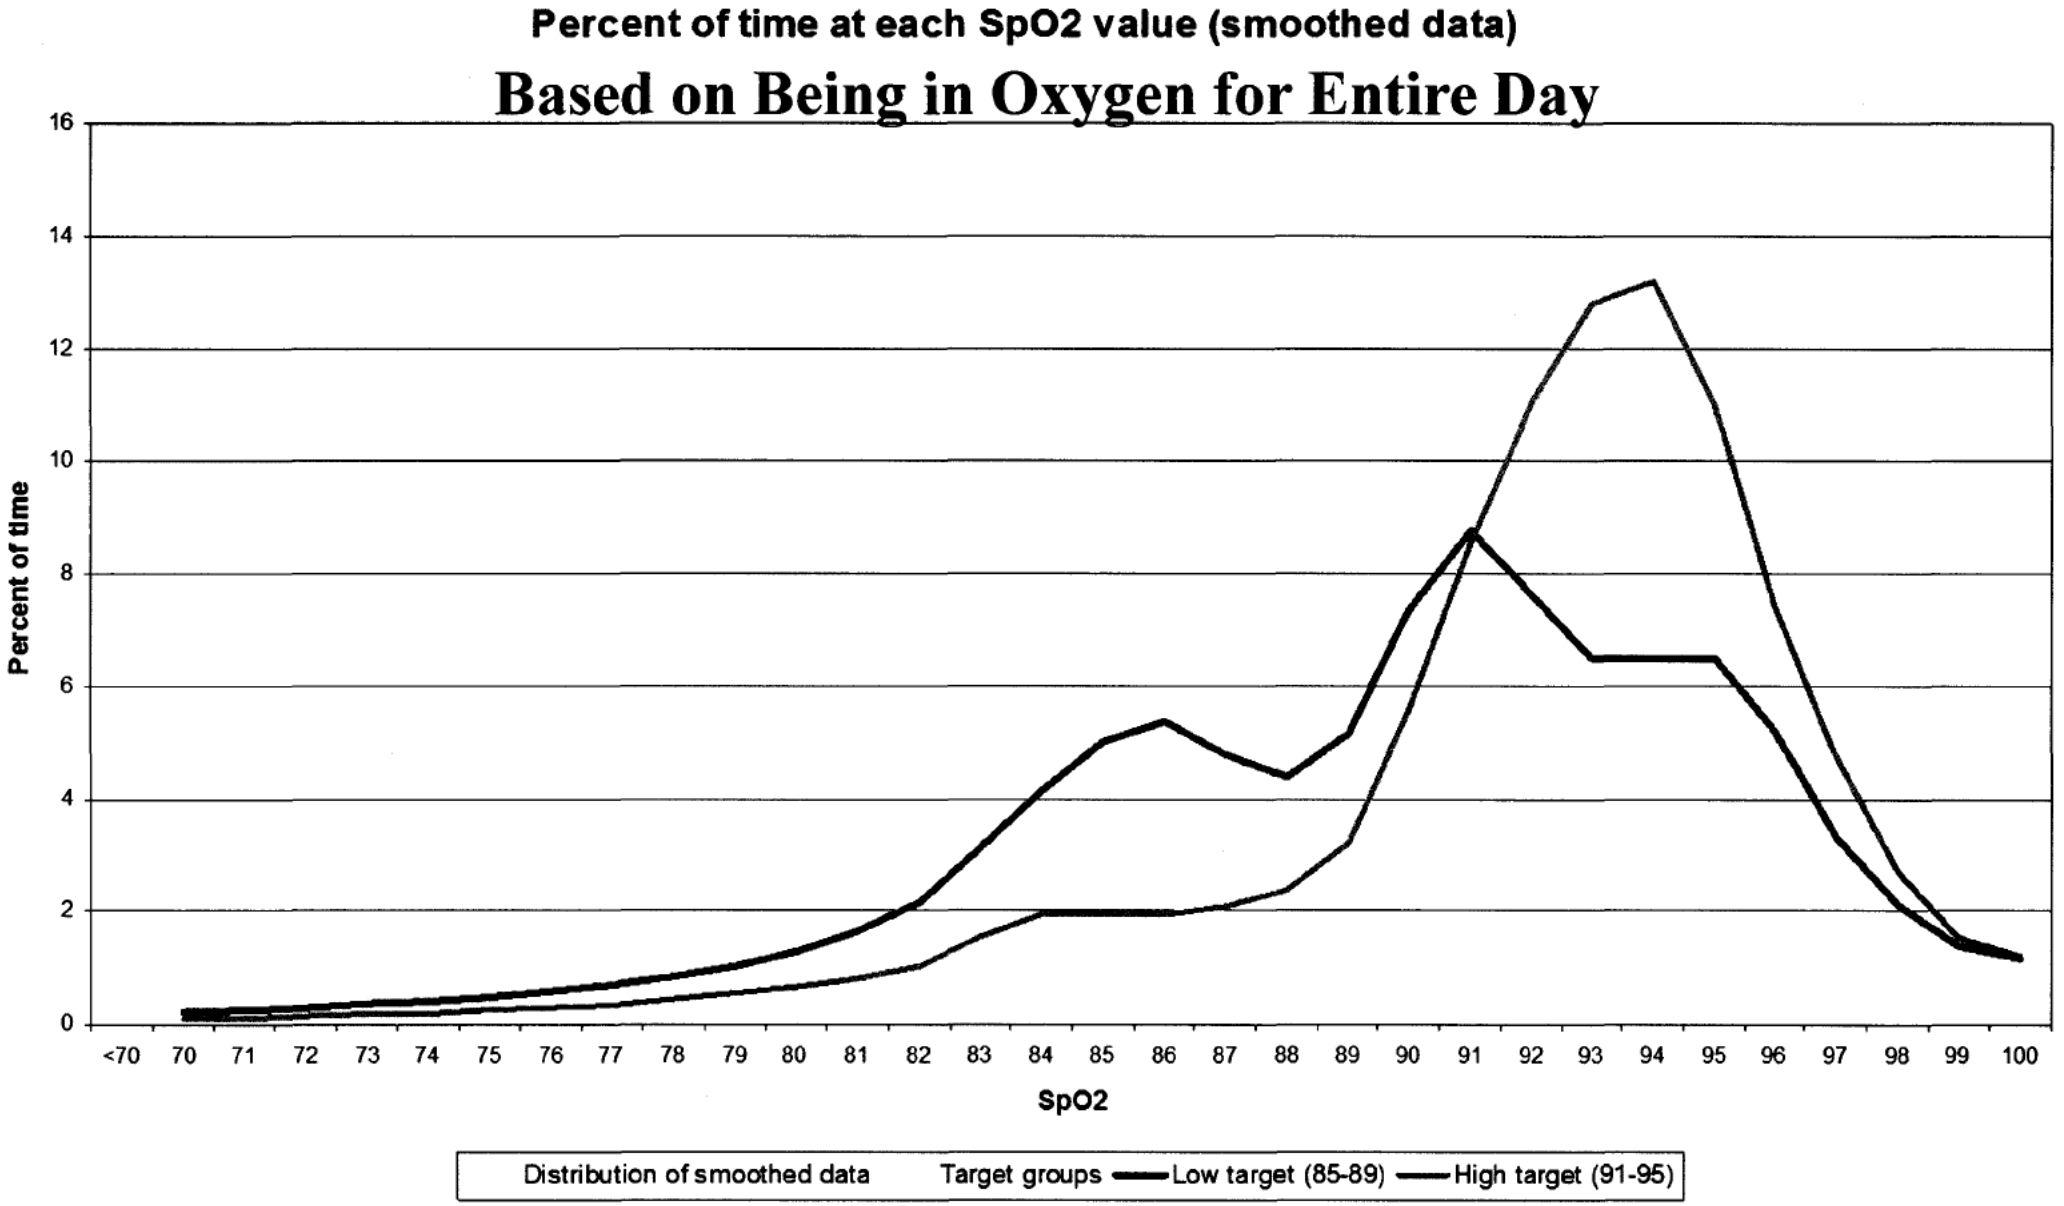
Range Assigned	High target (91-95)	Low target (85-89)
< 84%	6.40%	13.3%
> 96%	12.5%	9.39%

Response to DSMC: Safety Issue of SpO2>95%

- **We believe that neither oximeter group in the SUPPORT trial is being exposed to excessive durations of SpO2 > 95% based on all currently available information and the actual SUPPORT Trial Data analyzed to date.**
- **Current analyses demonstrate that the highest duration of SpO2 > 95% was 22.9%, and > 96% was 12.5% using only infants known to be in oxygen for all 3 daily data points in the first 14 days of life,.**
- **These values are previously unreported for such a population, and significantly less than the original data reviewed by the DSMC.**

Response to DSMC:
Futility regarding Separation of Oximeter Groups

- **An evaluation of the oximeter group data has revealed that there is a difference in the mean - 90% vs 92% and median values for the 2 groups – 92% vs 94%**
- **The Median SpO2s obtained using only days that were in oxygen at all 3 data points were 91% vs 93%**
- **These additional analyses have demonstrated that the cumulative time spent with an SpO2 of 90% or less is 22.80% (91% - 95%) versus 47.6% (85% - 89%) for a > 24% absolute difference between the groups.**



Response to DSMC:
Futility regarding Separation of Oximeter Groups

- **We examined the actual FiO2 requirement of the infants in the Oximeter arms.**
- **If the algorithms were working as intended, then there should be a difference in the FiO2 requirement between the groups**

Response to DSMC:

Futility regarding Separation of Oximeter Groups

- **The Actual time spent in Room Air during the first 14 days of life was 26.6% versus 35.5% for the 91%-95% group compared to the 85%-89% group.**
- **These differences persisted for data beyond 14 days**
- **The 2 groups remained separated by at least 3% duration for FiO2s of $\leq$ 50%**

Response to DSMC:
Futility regarding Separation of Oximeter Groups

- **The time in actual Target using only days when infants are in oxygen for all 3 data points**

91-95% = 55% 85% - 89% = 24.6%

Response to DSMC:
Futility regarding Separation of Oximeter Groups

- **The 91% - 95% are more in target because their alarm sounds when they reach 95%**
- ✘ **The 85% - 89% are less time in target because when their SpO2 is > 89% (a reading of 93%) there is no alarm. The alarm only sounds at a reading of 95%**
- ✓ **We believe that we can improve this time in range by lowering the high alarm to 94%**

Response to DSMC:
Futility regarding Separation of Oximeter Groups

- **It is uncertain what duration of differences in either SpO2 of FiO2 will be associated with different short and long term outcomes, but we are achieving some separation in both to the present.**
- **We believe that greater separation is possible and desirable and have made a number of recommendations to ensure that this will occur.**

Response to DSMC:

Suggestions for Increasing Separation of Oximeter Groups

1. **Set high SpO2 limit – alarm to 94%. This will reduce the duration of SpO2 values > 95% for both groups, and should increase the time both groups spend in the narrow target range.**
2. **Require documentation that the oximeters alarm limits are set and functional as per protocol every 4-6 hours**
3. **Change our data collection for FiO2 to ensure that subsequent interval reports more accurately reflect saturations measured while on oxygen therapy and exclude saturations of infants in room air**

Response to DSMC:

Suggestions for Increasing Separation of Oximeter Groups

4. Further training and in-service at all the sites to stress the importance of keeping the SpO2 alarms functional and at the limits of 85% and 95%. We will use the OWL (Oxygen with Love Program) developed at Oschner.
5. Develop guidelines for managing desaturations such that the increase in oxygen is proportional to the desaturation
6. Place bedside cards to indicate the desired target range

Response to DSMC:

Suggestions for Increasing Separation of Oximeter Groups

7. **Initiate compliance monitoring visits coordinated by RTI to visit random sites**
8. **Reanalyze group differences after an additional 100-150 infants have been enrolled.**
9. **Utilize only actual SpO2 values for assessment of safety in subsequent analyses ie; SpO2 < 84% and > 96%, and analyze only actual time in oxygen.**

Response to DSMC

- **The SUPPORT Trial Committee and the Network Steering Committee appreciate the diligence and suggestions of the Data Safety Monitoring Committee**
- **We trust that our response and suggestions to improve the SUPPORT Trial are found acceptable and that we may be allowed to continue this important trial.**

Attachments:	SUPPORT Trial DSMC Response - Final Dec 11.ppt Percent of time spent at each SpO2 value (FiO2 gt21) 12-5-05.doc Daily FiO2 for first 14 days.doc

Hi Betty and Rose and Everyone

I am sorry to keep modifying our response but I want our presentation to be tight, factual, and convincing. I would like this PowerPoint presentation to be sent to the DSMC for the call on Tuesday. I will use this in the time allocated to me – I can do this in 15 minutes leaving lots of time for questions. If you feel that any of the additional analyses should also be sent to them, these are attached.

Please let me know if you find any errors – I have reviewed it so often it is all beginning to blur!

Be well

Neil

SUPPORT Trial
Response to the DSMC

Neil Finer – Principal Investigator

For the SUPPORT Subcommittee and the Steering Committee

NICHD Neonatal Research Network

December 11 2005

Report of the DSMC Nov 2005

The DSMC expressed 2 concerns:

1. **There is a significant safety and exposure issue for the infants in the high saturation treatment group because an unacceptably high proportion of time was spent by these study subjects in the >95% range**

Report of the DSMC Nov 2005

2. There is a futility concern for this arm of the trial in that there does not appear to be substantial separation between the two high and low saturation treatment groups, and the babies are not being kept in the target range the appropriate amount of time in order to meaningfully test the oxygen saturation intervention as originally designed.

Evidence for Current SpO2 Ranges

- **SUPPORT Trial alarm limits were chosen as those most currently utilized within the Network and consistent with current evidence.**
- **To maintain PaO2 between 40 and 90mmHg would require SpO2 alarms of 92.5% to 95% (Paky et al Acta Paediatr. 1995 Jun; 84(6):613-6.)**

Evidence for Current SpO2 Ranges

- No current prospective studies that have evaluated actual durations of time at various SpO2 levels
- Median SpO2 in healthy preterm infants = 97% (Ng et al Arch Dis Child 1998;79:F64)
- All published studies reported target ranges ie lower vs higher using High SpO2 limits -92% vs 95% for populations but did not present any data as to how well these target were adhered to.
- Sun et al compared units with upper limits of >95% with those of $\leq$ 95% (Ped Res 2002, 51:350A)

Evidence for Current SpO2 Ranges

- **Tin et al reported units by the limits they set without any individual patient data (Tin et al Arch Dis Child 2001;84:F106)**
- **Another survey compared SpO2 limits > 98% with ≤ 98%, and early limits – first 2 weeks- of > 92% vs < 92% (Anderson Ped Res 2002;51:367A)**
- **Chow et al reported on a change of practice with lowering of the SpO2 limit and other changes – They did not provide any actual SpO2 data (Chow et al, Pediatr 2003;111:339)**
- **All of these studies suggested that lower SpO2 limits were associated with less ROP.**

Evidence for Current SpO2 Ranges

- **Prior to the initiation of SUPPORT – there were no data indicating the actual percent of time ELBW infants spend at different SpO2 values or ranges**
- **The design of the trial using oximeter downloads was unique and will provide this information based on a large prospective cohort**
- **This trial was also unique in collecting this data from 2 hours of age in acutely unstable ELBW infants until there are out of oxygen**

Response to DSMC

Safety Issue of SpO2>95%

Concern regarding safety issue of duration of SpO2 > 95%

- ✓ **The current best data utilizing actual oximeter data is from Hagadorn et al (PAS 2004 Abstract: Late Breaker)**
- ✓ **Evaluated 78 ELBW infants for 70 hours per week for the first 4 weeks of life**
- ✓ **Lower and upper SpO2 limits were 83% -92% and 92%-98%**
- ✓ **Median SpO2 = 95%**
- ✓ **Medians from SUPPORT Oximeter groups – 92% and 94%, and for infants only in oxygen for the entire day the medians are 91% vs 93%.**

Response to DSMC:
Safety Issue of SpO2>95%

- STOP-ROP high treatment infants spent 97% of time > 95%
- Case Western a current NRN Center – Current data from SUPPORT type ELBW infants – SpO2 > 95% for > 50% time
- SUPPPORT Infants on room air – SpO2 > 95% from 46% to 69% of time

Response to DSMC:
Safety Issue of SpO2>95%

- **Additional analyses evaluated the duration of time at SpO2 values of 98%, 99% and 100% as these may represent very high PaO2 values**
- **Infants in SUPPORT in ROOM Air spend more time at these values than infants receiving oxygen – 32% - 38% versus 5%-6%**

SUPPORT Trial Actual Results

91% - 95% Room Air 85% - 89%

	%	Cum %	%	Cum%
98%	15.49%	77.15	13.65%	81.42
99%	12.94%	90.09	10.37%	91.79

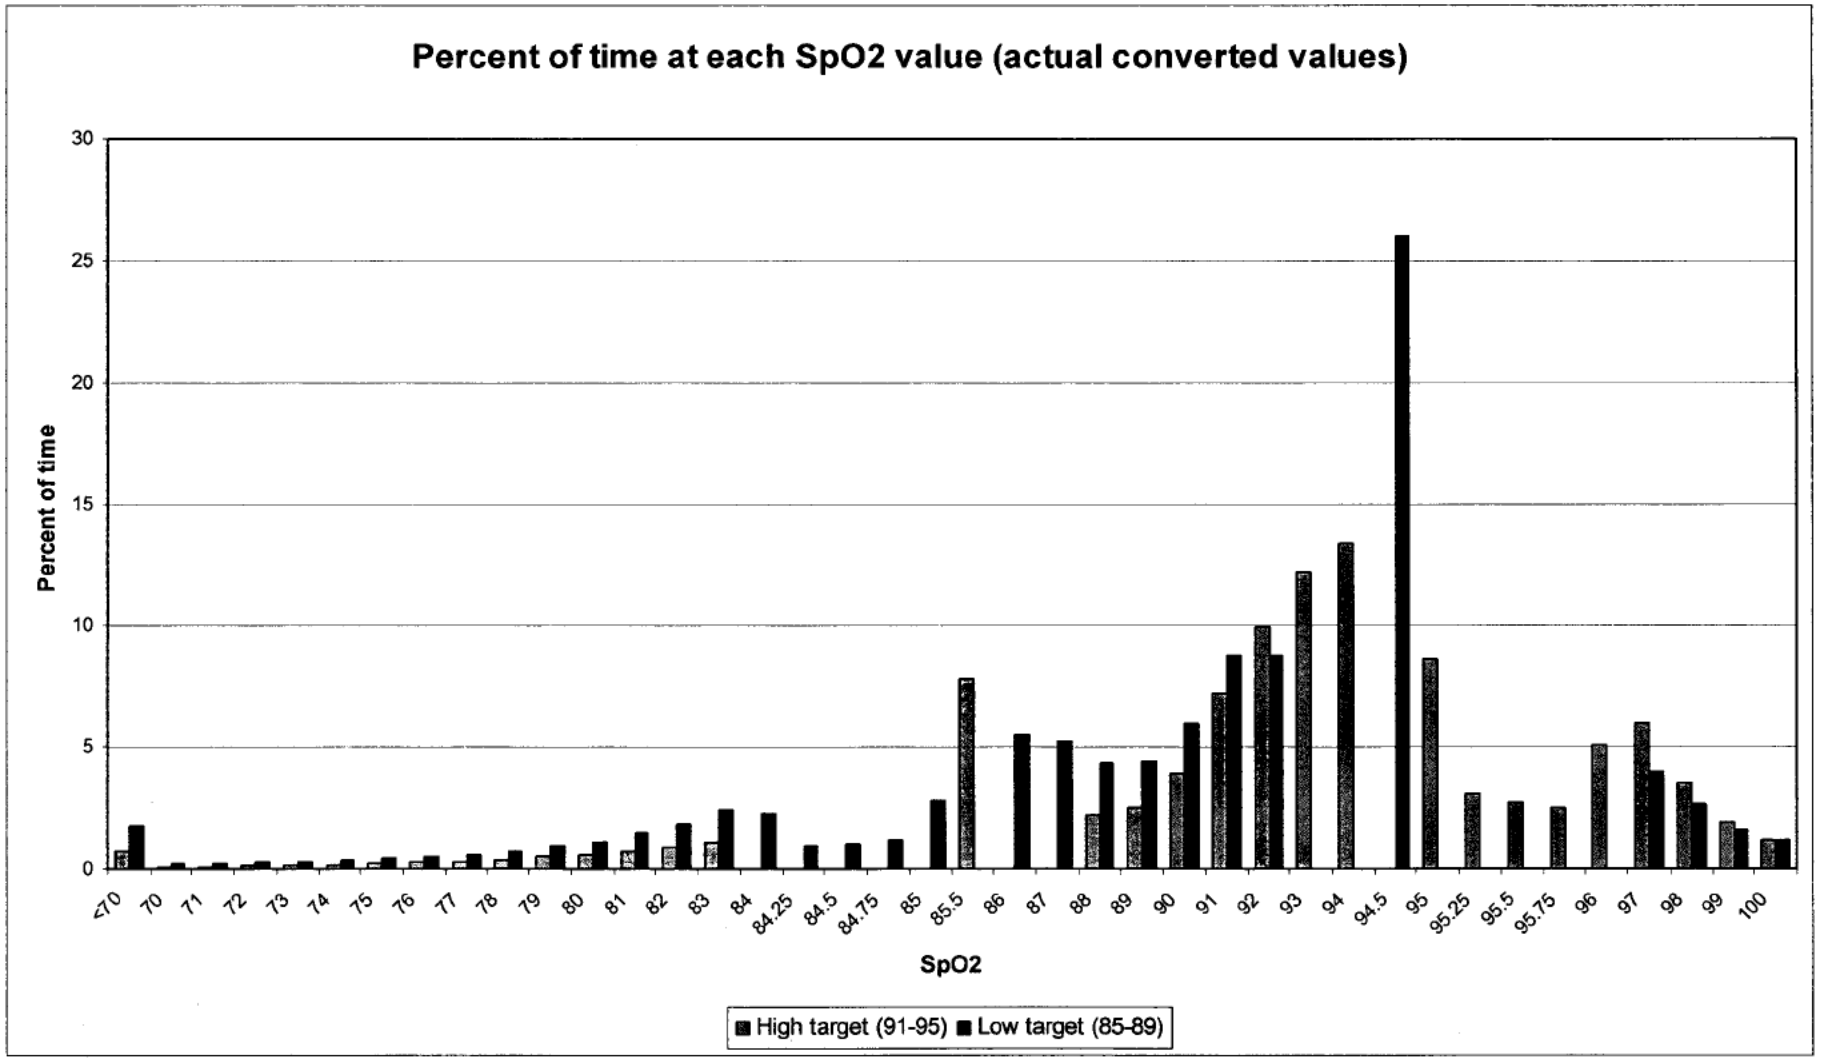
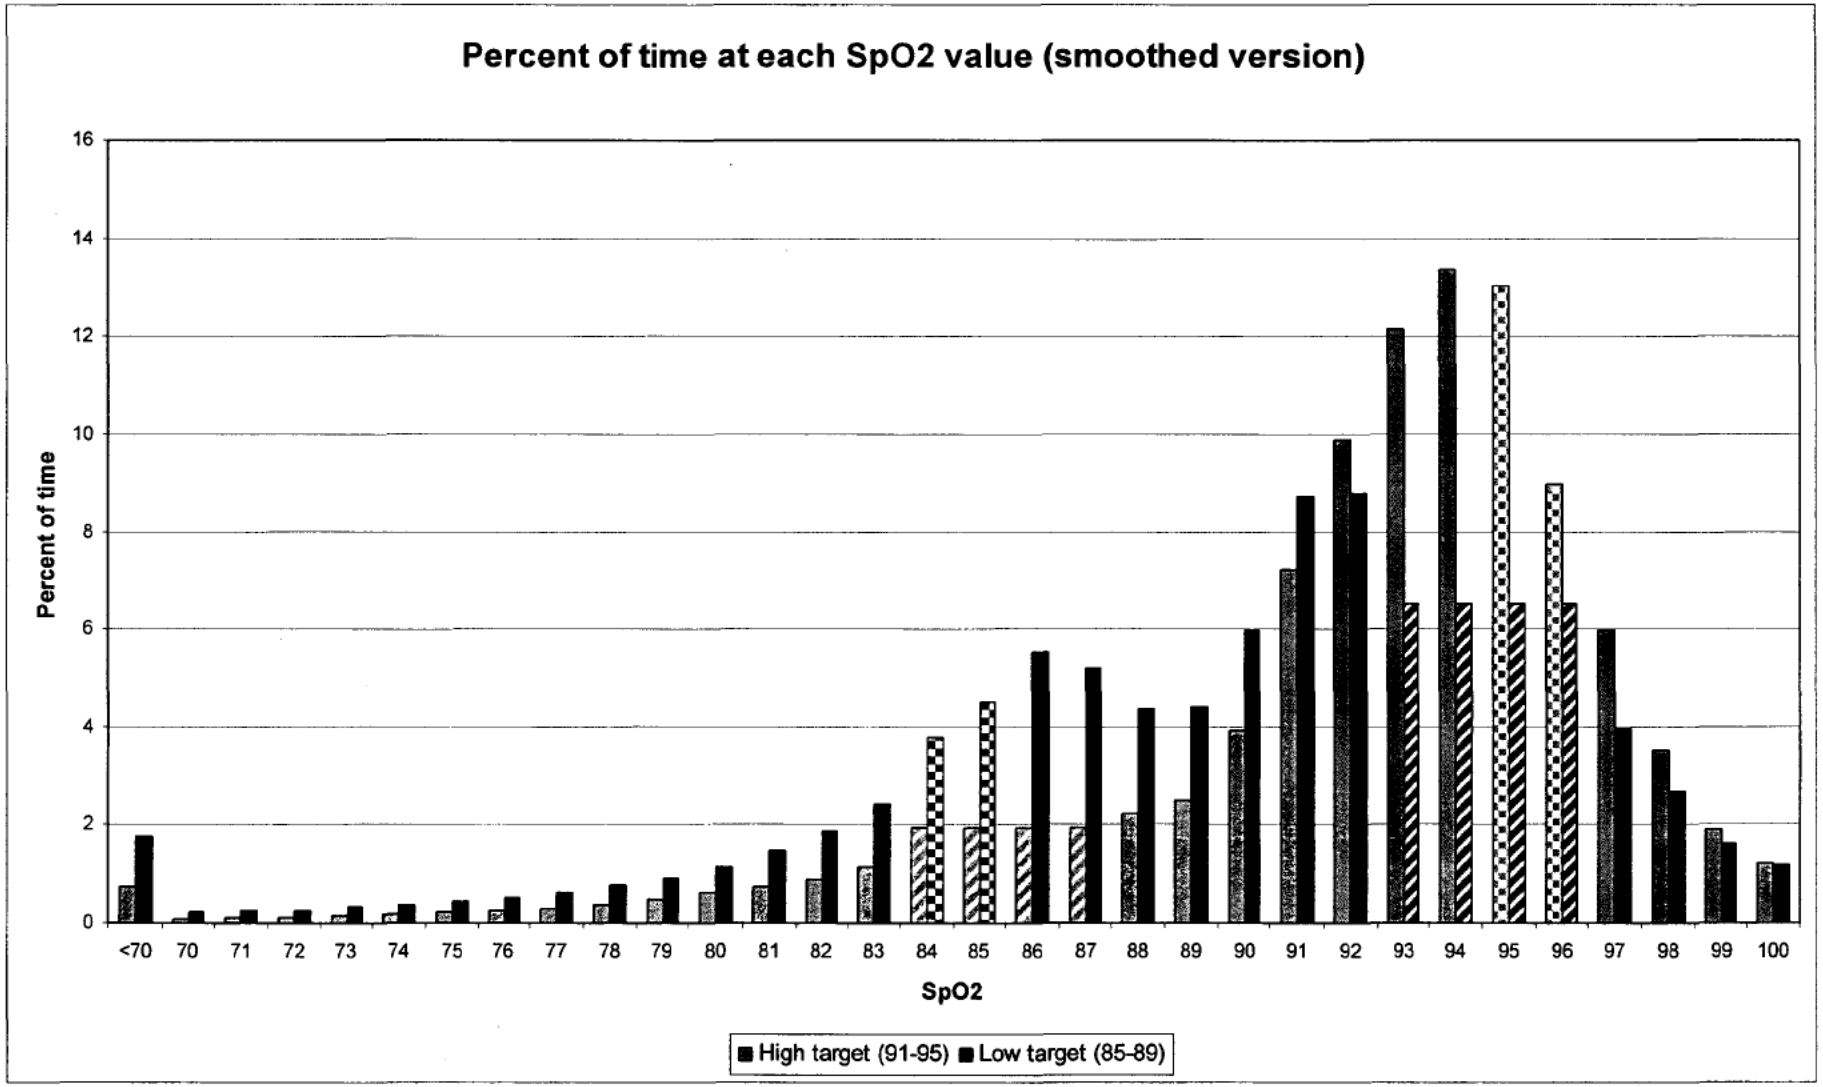
>96	12.56	9.39

The graph below displays each individual converted SpO2 value



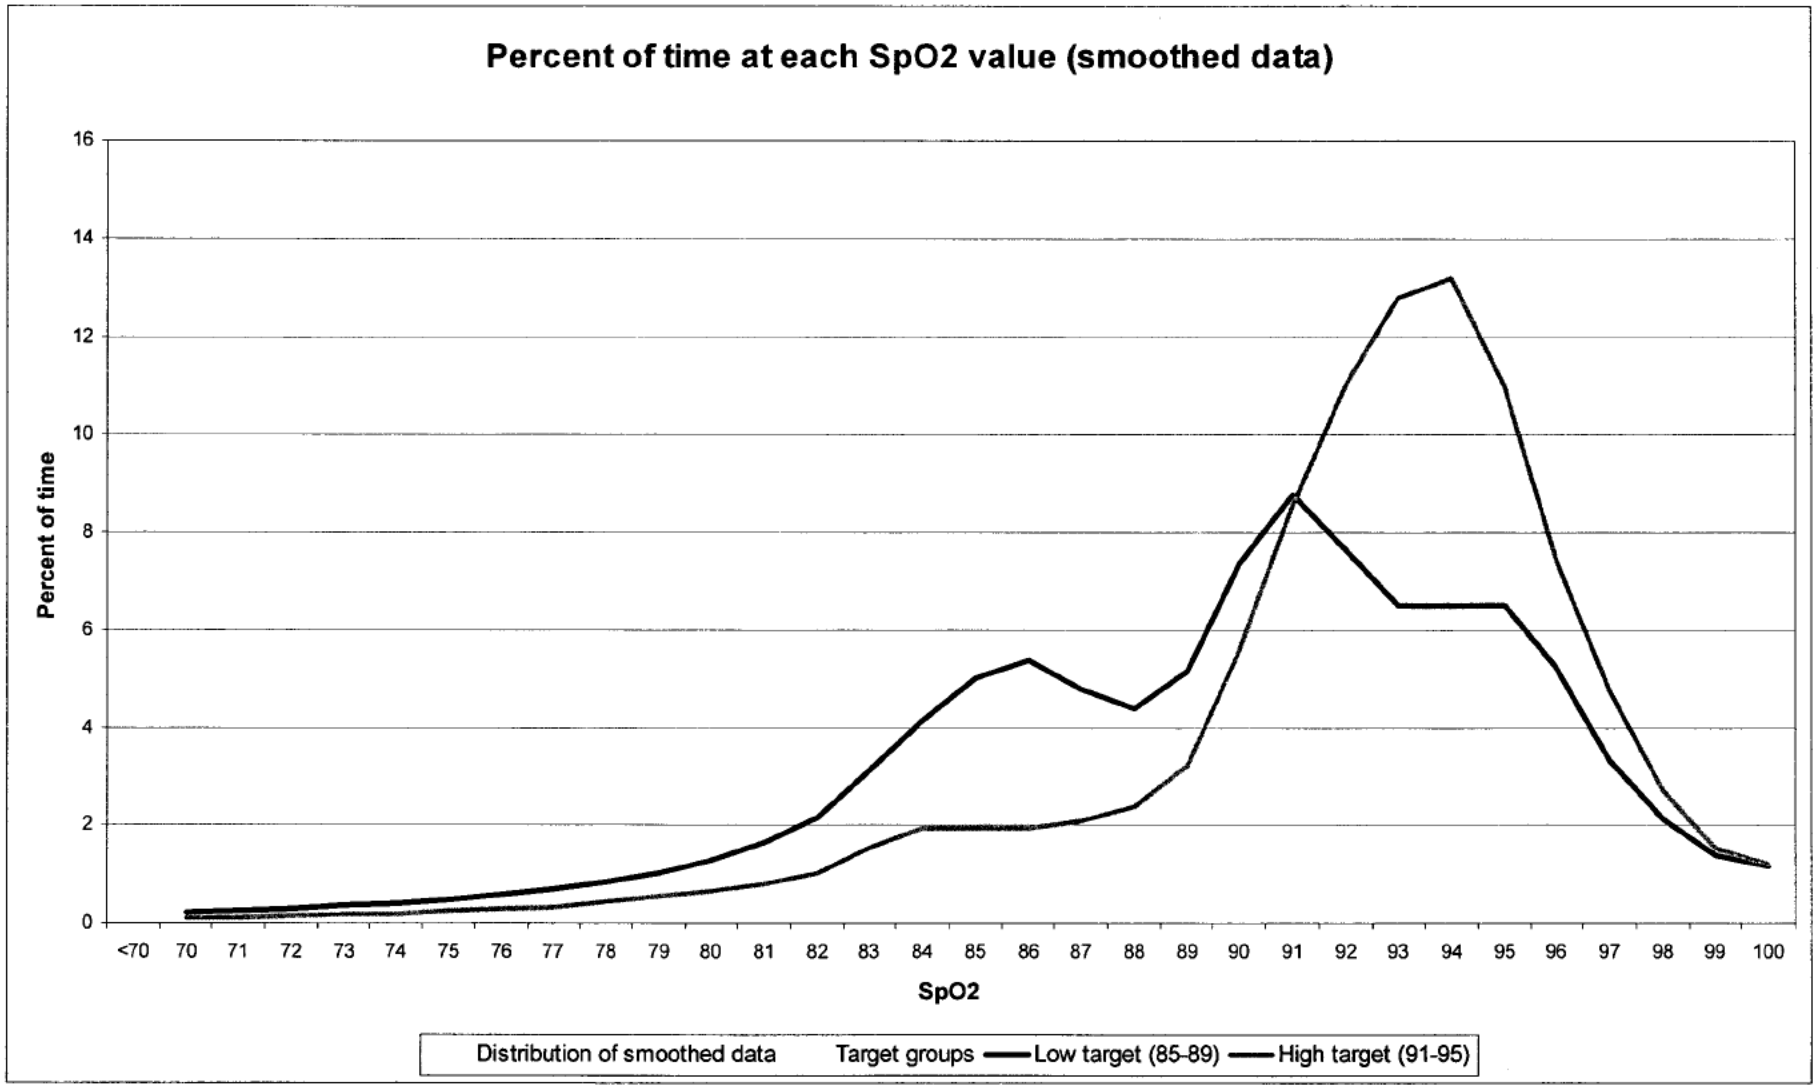
In the graph below, the converted SpO2 values have been smoothed to give a better idea of the distribution. Adjustments made to smooth the data are listed on the following page. Patterns are used to identify altered values.



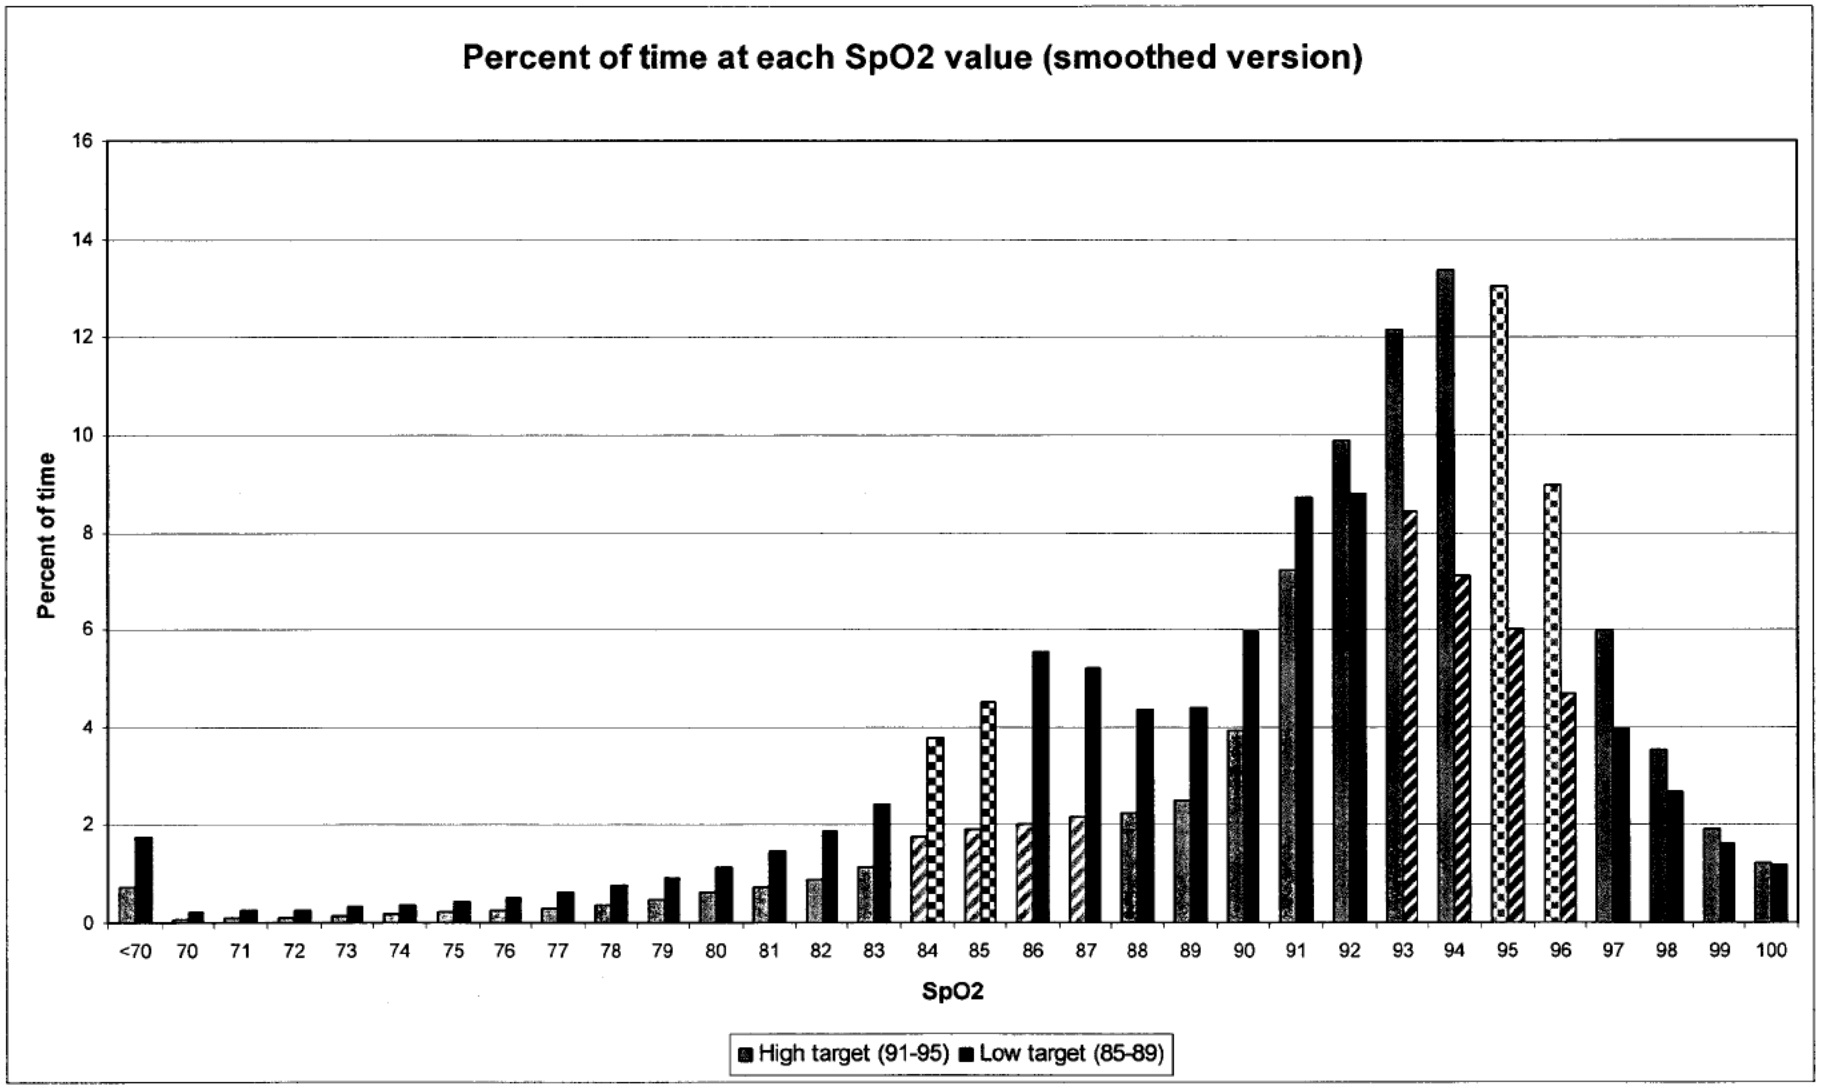
Changes made to achieve smoothing

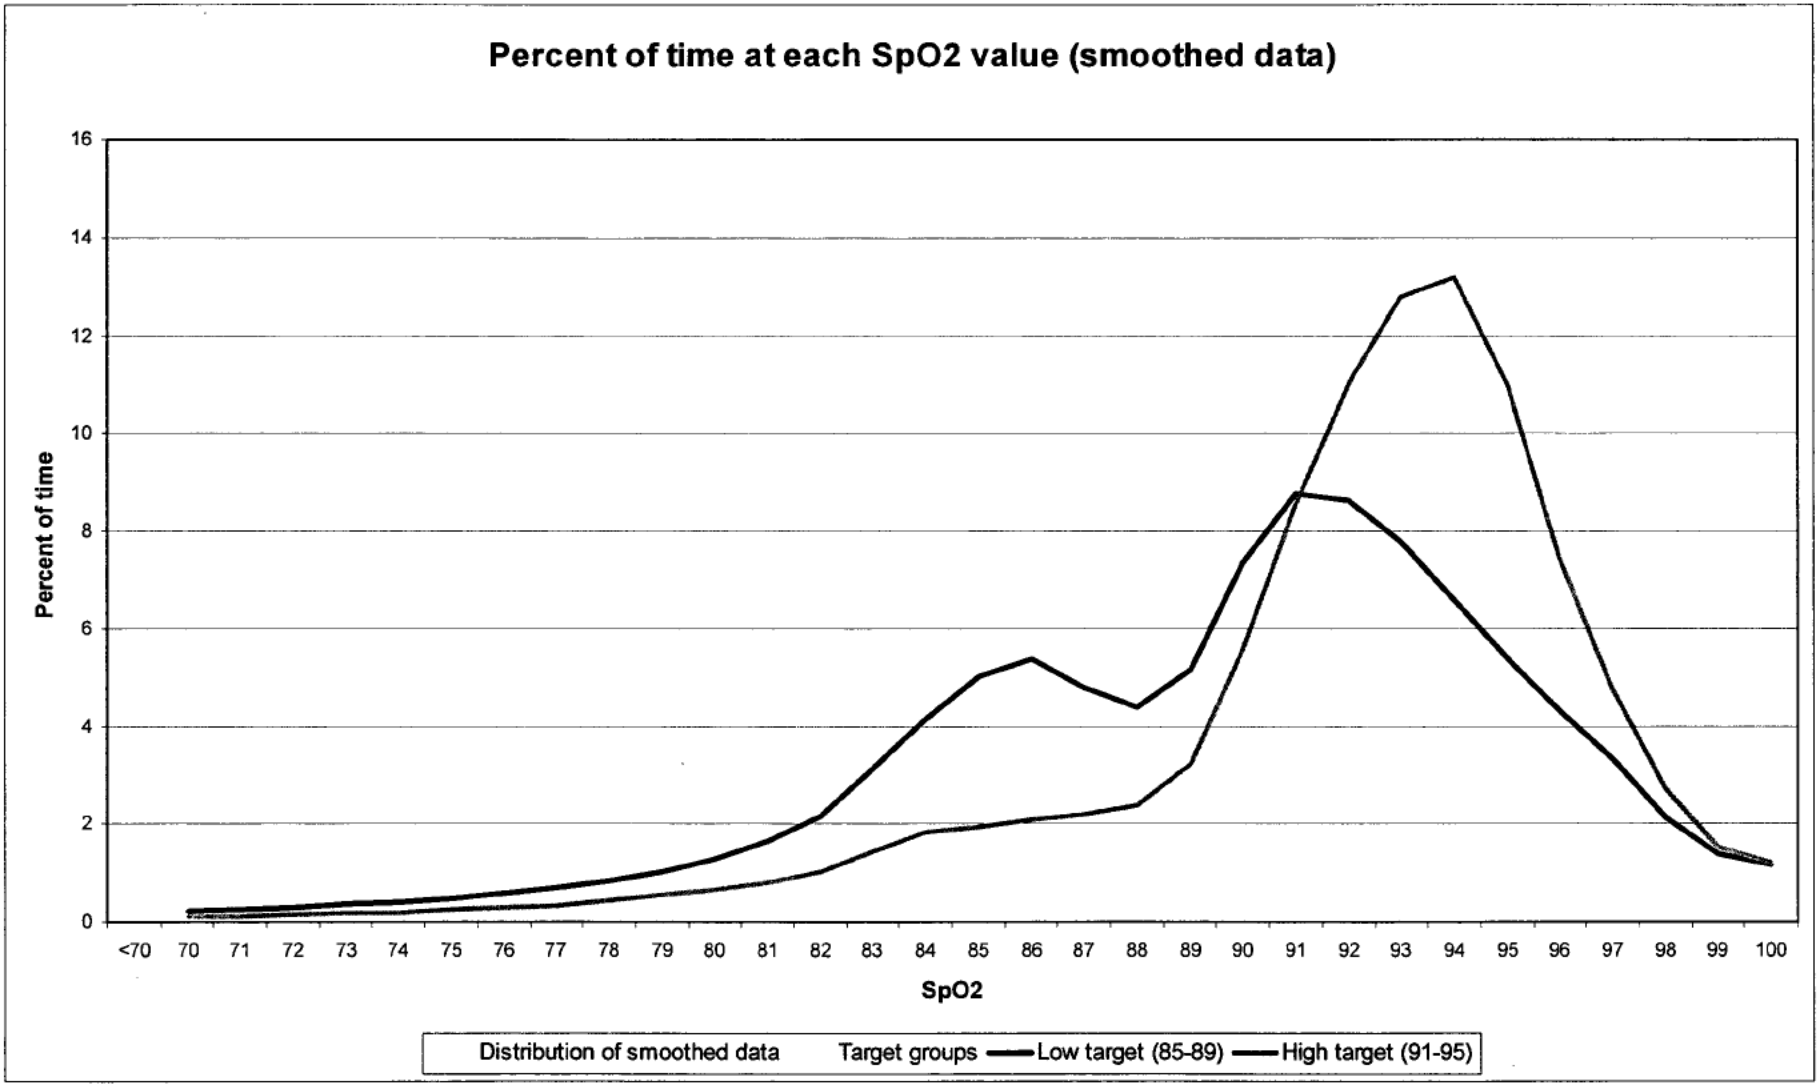
High target (91-95)	Pattern
Percent of time at converted value of 85.5 are spread evenly over 84-87	Blue diagonal stripes
Percent of time at 95 includes converted values of 95, 95.25 and half the percent of time at 95.5	Blue checked
Percent of time at 96 includes converted values of 96, 95.75 and half the percent of time at 95.5	Blue checked

Low target (85-89)	Pattern
Percent of time at converted value of 94.5 are spread evenly over 93-96	Burgundy diagonal stripes
Percent of time at 84 includes converted values of 84, 84.25 and half the percent of time at 84.5	Burgundy checked
Percent of time at 85 includes converted values of 85, 84.75 and half the percent of time at 84.5	Burgundy checked



The following two graphs are the result of some additional smoothing.





Daily FiO2 values for first 14 days of life
Average daily FiO2 for each infant (average of 3 FiO2 measurements on SUPP05)
Includes data on 155 infants (73 High target, 82 Low target) for whom pulse oximeter data is available
12-5-05

Summary statistics

FiO2	High target (91-95)	Low target (85-89)
Mean	0.315	0.294
Maximum	1.000	1.000
90th percentile	0.500	0.447
75th percentile	0.466	0.317
Median	0.260	0.247
25th percentile	0.213	0.210
10th percentile	0.210	0.210
Minimum	0.210	0.210

Full distribution

Daily average FiO2 (interval lower bound)	High target (91-95)		Low target (85-89)	
	Percent	Cumulative	Percent	Cumulative

Thanks Neil
I would not consider giving less than RA to anyone at this point-- without
a lot of convincing data!!!!
BJS<nfiner@ucsd.edu> writes:

---

Hi Rose and Everyone
I have spoken to Barbara and had email exchanges with Augusto.
My main issue at present is to have a clear presentation to the DSMC. I asked Marie to run some additional analyses. She also ran the data for only those days that the infants were in oxygen at all 3 time points as this is the best data to trim out the room air contamination.
The actual data is increasingly beneficial as it shows less real time > 95%, and maintains the groups separation. It also shows that 91% to 95% group in narrow target for about 55% of the time with 85% to 89% being in target about 25% of the time. I think lowering the high alarm to 94% will increase this time in target in booth groups.
I would like to use the PowerPoint for the DSMC
What do you think?
I have attached the newer analyses
Thanks for reviewing this
Neil

Neil
I spoke to Barbara regarding the recent email communication you had forwarded to me. She will likely call you.
We will develop language to post on either our public website or the clinicaltrials.gov website to inform folks of the trial pending the dsmc meeting and director recommendations next week for uniformity.
Thanks for you help and candor!
Rose

SUPPORT Trial
Response to the DSMC

Neil Finer – Principal Investigator

For the SUPPORT Subcommittee and the Steering Committee

NICHD Neonatal Research Network

December 9 2005

Report of the DSMC Nov 2005

The DSMC expressed 2 concerns:

1. There is a significant safety and exposure issue for the infants in the high saturation treatment group because an unacceptably high proportion of time was spent by these study subjects in the >95% range

Report of the DSMC Nov 2005

2. There is a futility concern for this arm of the trial in that there does not appear to be substantial separation between the two high and low saturation treatment groups, and the babies are not being kept in the target range the appropriate amount of time in order to meaningfully test the oxygen saturation intervention as originally designed.

Evidence for Current SpO2 Ranges

- No current prospective studies that have evaluated actual durations of time at various SpO2 levels
- Median SpO2 in healthy preterm infants = 97% (Ng et al Arch Dis Child 1998;79:F64)
- All published studies reported target ranges ie lower vs higher using High SpO2 limits -92% vs 95%) for populations but did not present any data as to how well these target were adhered to.
- Sun et al compared units with upper limits of >95% with those of $\leq$ 95% (Ped Res 2002, 51:350A)

Evidence for Current SpO2 Ranges

- **To maintain PaO2 between 40 and 90mmHg would require SpO2 alarms of 92.5% to 95% (Paky et al Acta Paediatr. 1995 Jun; 84(6):613-6.)**

Evidence for Current SpO2 Ranges

- **Tin et al reported units by the limits they set without any individual patient data (Tin et al Arch Dis Child 2001;84:F106)**
- **Another survey compared SpO2 limits > 98% with ≤ 98%, and early limits – first 2 weeks- of > 92% vs < 92% (Anderson Ped Res 2002;51:367A)**
- **Chow et al reported on a change of practice with lowering of the SPo2 limit and other changes – They did not provide any actual SpO2 data (Chow et al, Pediatr 2003;111:339)**
- **All of these studies suggested that lower SpO2 limits were associated with less ROP.**

Evidence for Current SpO2 Ranges

- **Prior to the initiation of SUPPORT – there were no data indicating the actual percent of time ELBW infants spend at different SpO2 values or ranges**
- **The design of the trial using oximeter downloads was unique and will provide this information based on a large prospective cohort**
- **This trial was also unique in collecting this data from 2 hours of age in acutely unstable ELBW infants until there are out of oxygen**

Response to DSMC

Safety Issue of SpO2>95%

Concern regarding safety issue of duration of SpO2 > 95%

- ✓ **The current best data from Hagadorn et al evaluated 78 ELBW infants for 70 hours per week for the first 4 weeks of life**
- ✓ **Lower and upper limits were 83% -92% and 92%-98%**
- ✓ **Median SpO2 = 95%**
- ✓ **Medians from SUPPORT Oximeter groups – 92% and 94%, and for infants only in oxygen for the entire day the medians are 91% vs 93%.**

Response to DSMC:
Safety Issue of SpO2>95%

- STOP-ROP high treatment infants spent 97% of time > 95%
- Case Western a current NRN Center – Current data from SUPPORT type ELBW infants – SpO2 > 95% for > 50% time
- SUPPPORT Infants on room air – SpO2 > 95% from 46% to 69% of time

Response to DSMC:
Safety Issue of SpO2>95%

- **Additional analyses evaluated the duration of time at SpO2 values of 98%, 99% and 100% as these may represent very high PaO2 values**
- **Infants in SUPPORT in ROOM Air spend more time at these values than infants receiving oxygen – 32% - 38% versus 5%-6%**

SUPPORT Trial Actual Results

91% - 95% Room Air 85% - 89%

98%	15.49%	77.15	13.65%	81.42
99%	12.94%	90.09	10.37%	91.79
100%%	9.91%	100.00	8.21%	100.00
Total	**38.3%**		**32.2%**	

91% - 95% Oxygen 85% - 89%

98%	3.51%	96.90	2.66%	97.23
99%	1.90%	98.80	1.60%	98.83
100%	1.20%	100.00	1.17%	100.00
Total	**6.6%**		**5.4%**	

Response to DSMC: Safety Issue of SpO2>95%

- The actual algorithm for conversion of displayed versus actual values results in inability to create a whole value for each displayed value.
- We calculated the time that infants were > 96%

  and < 84%
- These values may be the first such data for a large group of ELBW infants that has been reported.
- These values appear lower than any previous reports

Response to DSMC: Safety Issue of SpO2>95%

Percent of time of spent at SpO2 < 84% and > 96% (RTI Analyses In Oxygen, Dec 2, 2005)

Range Assigned	High target (91-95)	Low target (85-89)
< 84%	8.30%	14.05%
> 96%	21.45%	15.47%

Response to DSMC: Safety Issue of SpO2>95%

- **We believe that neither oximeter group in the SUPPORT trial is being exposed to excessive durations of SpO2 > 95% based on all currently available information and the actual SUPPORT Trial Data analyzed to date.**
- **Current analyses demonstrate that the highest duration of SpO2 > 95% was 28.13%, the lowest value that we believe has been reported for any group of preterm infants. In addition for some of the time in this analyses, infants were receiving room air, which increases SpO2 values > 96%**

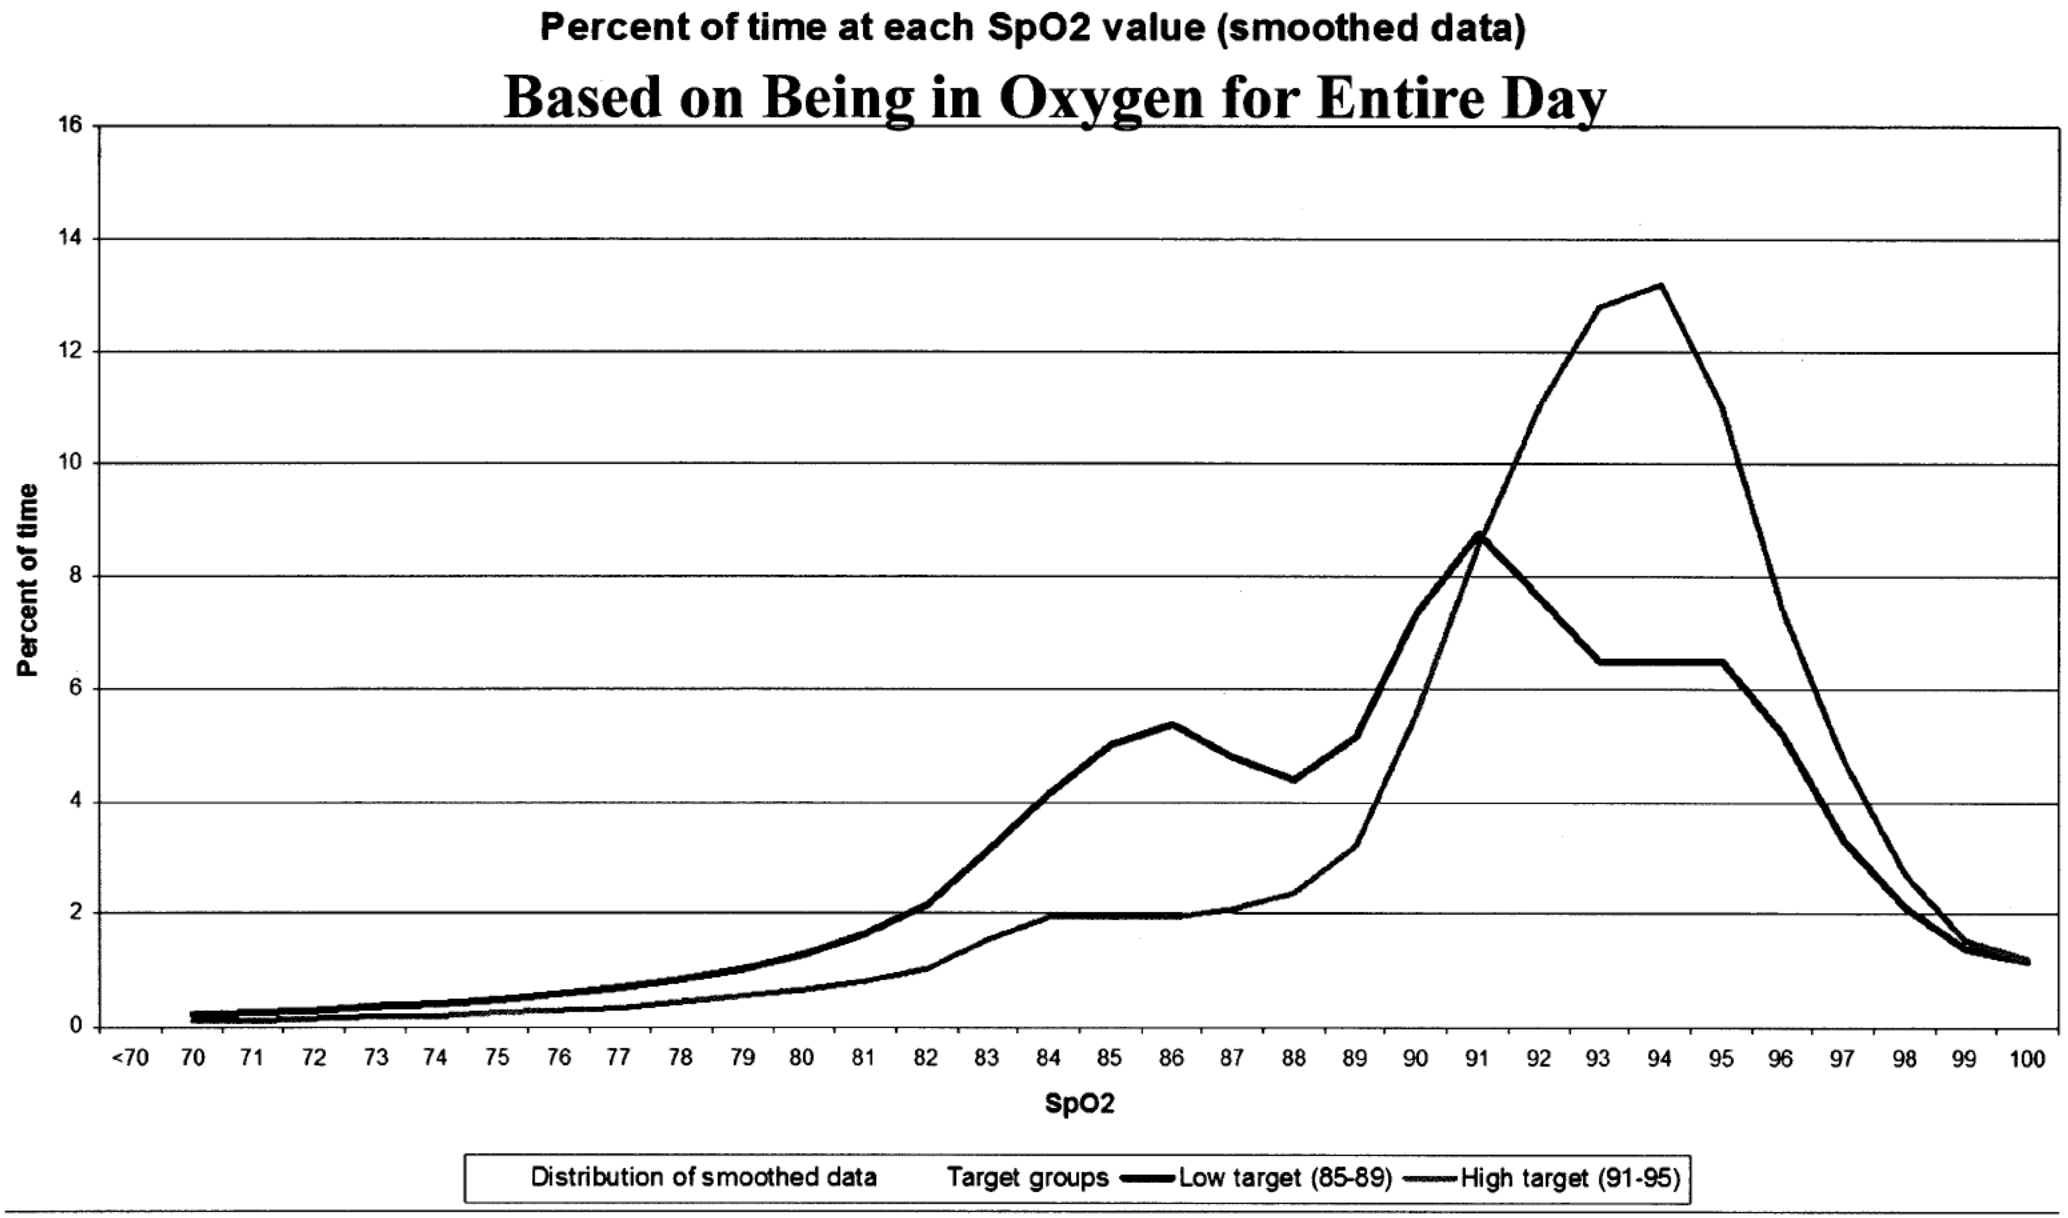
Response to DSMC:
Futility regarding Separation of Oximeter Groups

- **Further analyses which included only infants on Oxygen at all 3 data points for a given day revealed even less duration of SpO2 > 96% - 20.2% vs9.39%**
- **This analyses avoids the contamination of room air time with resultant higher SpO2 values**

Range Assigned	Data for days in Oxygen – all 3 data points > .21 High target (91-95)	Low target (85-89)
< 84%	6.40%	13.3%
≥ 96%	20.2%	9.39%

Response to DSMC:
Futility regarding Separation of Oximeter Groups

- **An evaluation of the oximeter group data has revealed that there is a difference in the mean - 90% vs 92% and median values for the 2 groups – 92% vs 94%**
- **The Median SpO2s obtained using only days that were in oxygen at all 3 data points were 91% vs 93%**
- **These additional analyses have demonstrated that the cumulative time spent with an SpO2 of 90% or less is 22.8.0% (91% - 95%) versus 47.6% (85% - 89%) for a > 20% absolute difference between the groups.**



Response to DSMC:
Futility regarding Separation of Oximeter Groups

- **The time in actual Target using only days when infants are in oxygen for all 3 data points**

91-95% = 55% 85% - 89% = 24.6%

Response to DSMC:
Futility regarding Separation of Oximeter Groups

- **It is uncertain what duration of differences will be associated with different short and long term outcomes, but we are achieving some separation to the present.**
- **We believe that greater separation is possible and have made a number of recommendations to ensure that this will occur**

Response to DSMC:
Futility regarding Separation of Oximeter Groups

- **The 91% - 95% are more in target because their alarm sounds when they reach 95%**

✘ **The 85% - 89% are less time in target because when their SpO2 is > 89% (a reading of 93%) there is no alarm. The alarm only sounds at a reading of 95%**

✓ **We believe that we can improve this time in range by lowering the high alarm to 94%**

Response to DSMC:

Suggestions for Increasing Separation of Oximeter Groups

1. **Set high SpO2 limit – alarm to 94%. This will reduce the duration of SpO2 values > 95% for both groups, and should increase the time both groups spend in the narrow target range.**
2. **Require documentation that the oximeters alarm limits are set and functional as per protocol every 4-6 hours**
3. **Change our data collection for FiO2 to ensure that subsequent interval reports more accurately reflect saturations measured while on oxygen therapy and exclude saturations of infants in room air**

Response to DSMC:

Suggestions for Increasing Separation of Oximeter Groups

4. Further training and in-service at all the sites to stress the importance of keeping the SpO2 alarms functional and at the limits of 85% and 95%. We will use the OWL (Oxygen with Love Program) developed at Oschner.
5. Develop guidelines for managing desaturations such that the increase in oxygen is proportional to the desaturation
6. Place bedside cards to indicate the desired target range

Response to DSMC:

Suggestions for Increasing Separation of Oximeter Groups

7. **Initiate compliance monitoring visits coordinated by RTI to visit random sites**
8. **Reanalyze group differences after an additional 100-150 infants have been enrolled.**

Percent of time spent at each SpO2 value for infants with FiO2 > 0.21 at each of three timepoints recorded on SUPP05

Data processed as of 12/02/2005

Data included in tables and graphs

Infants included	High target (91-95)	Low target (85-89)	Total
Number	65	62	127

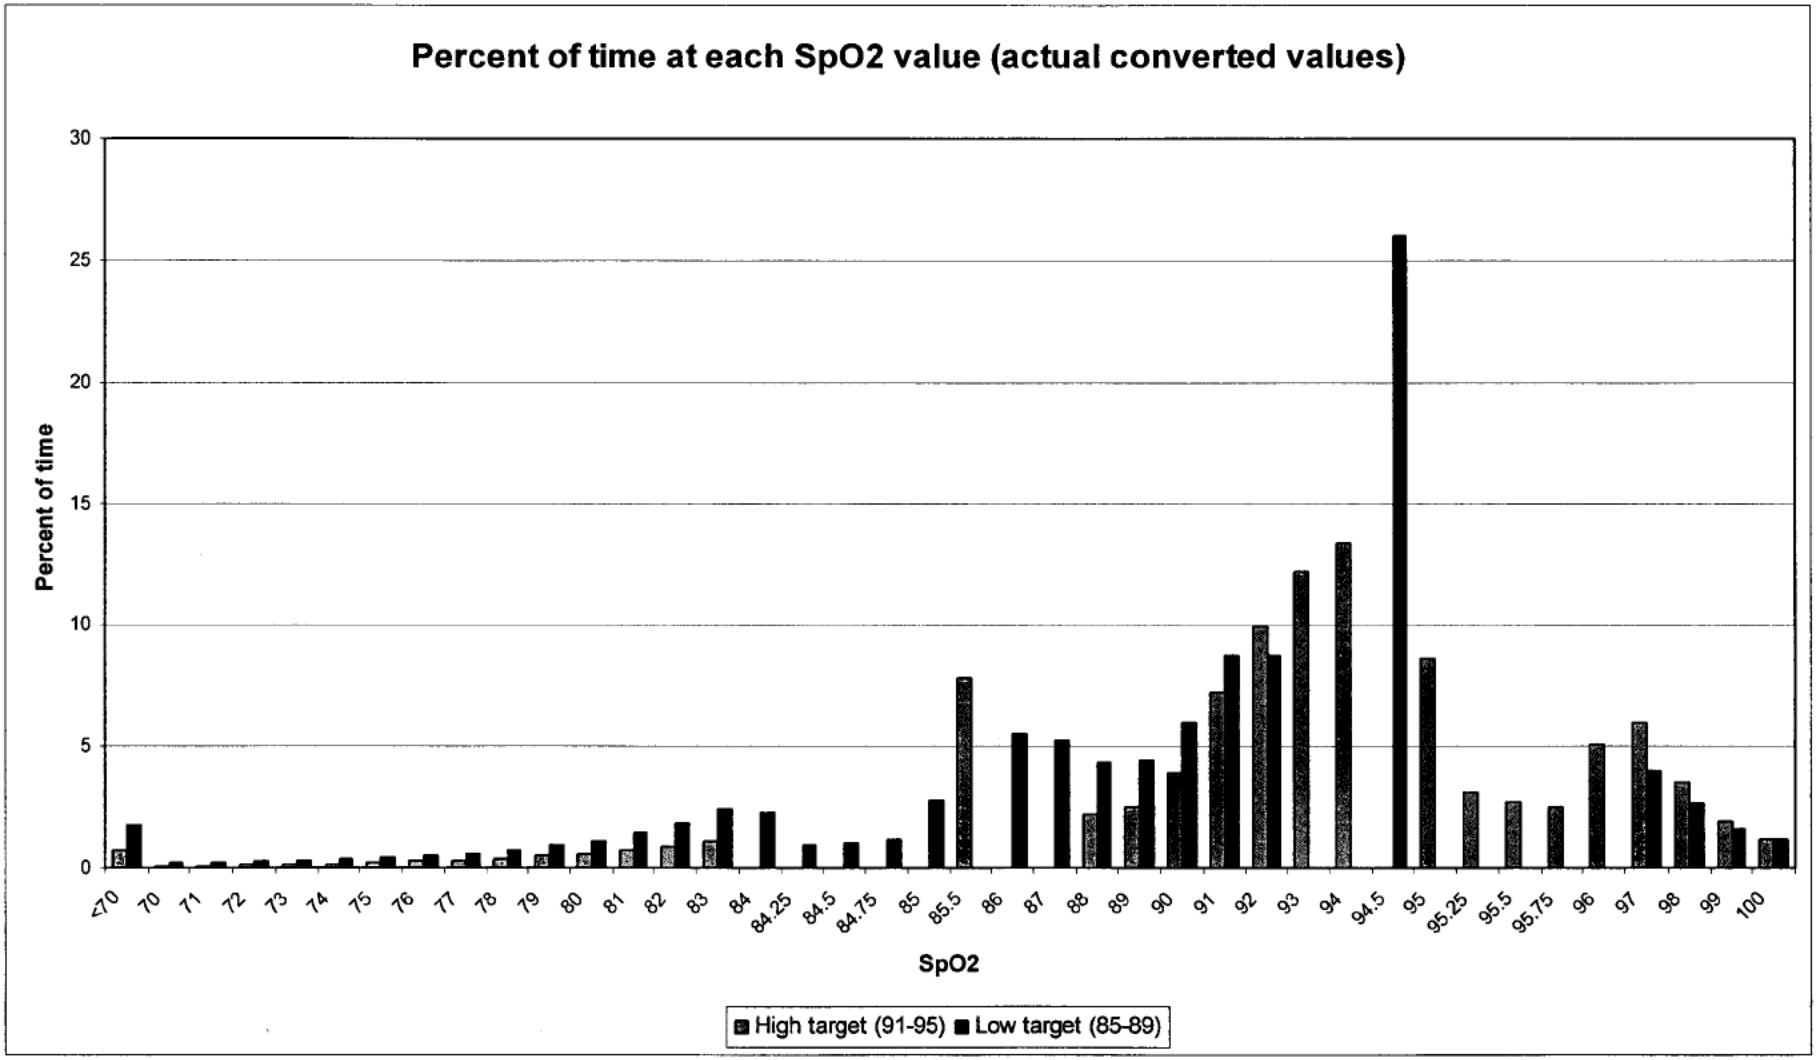
Median	93	91

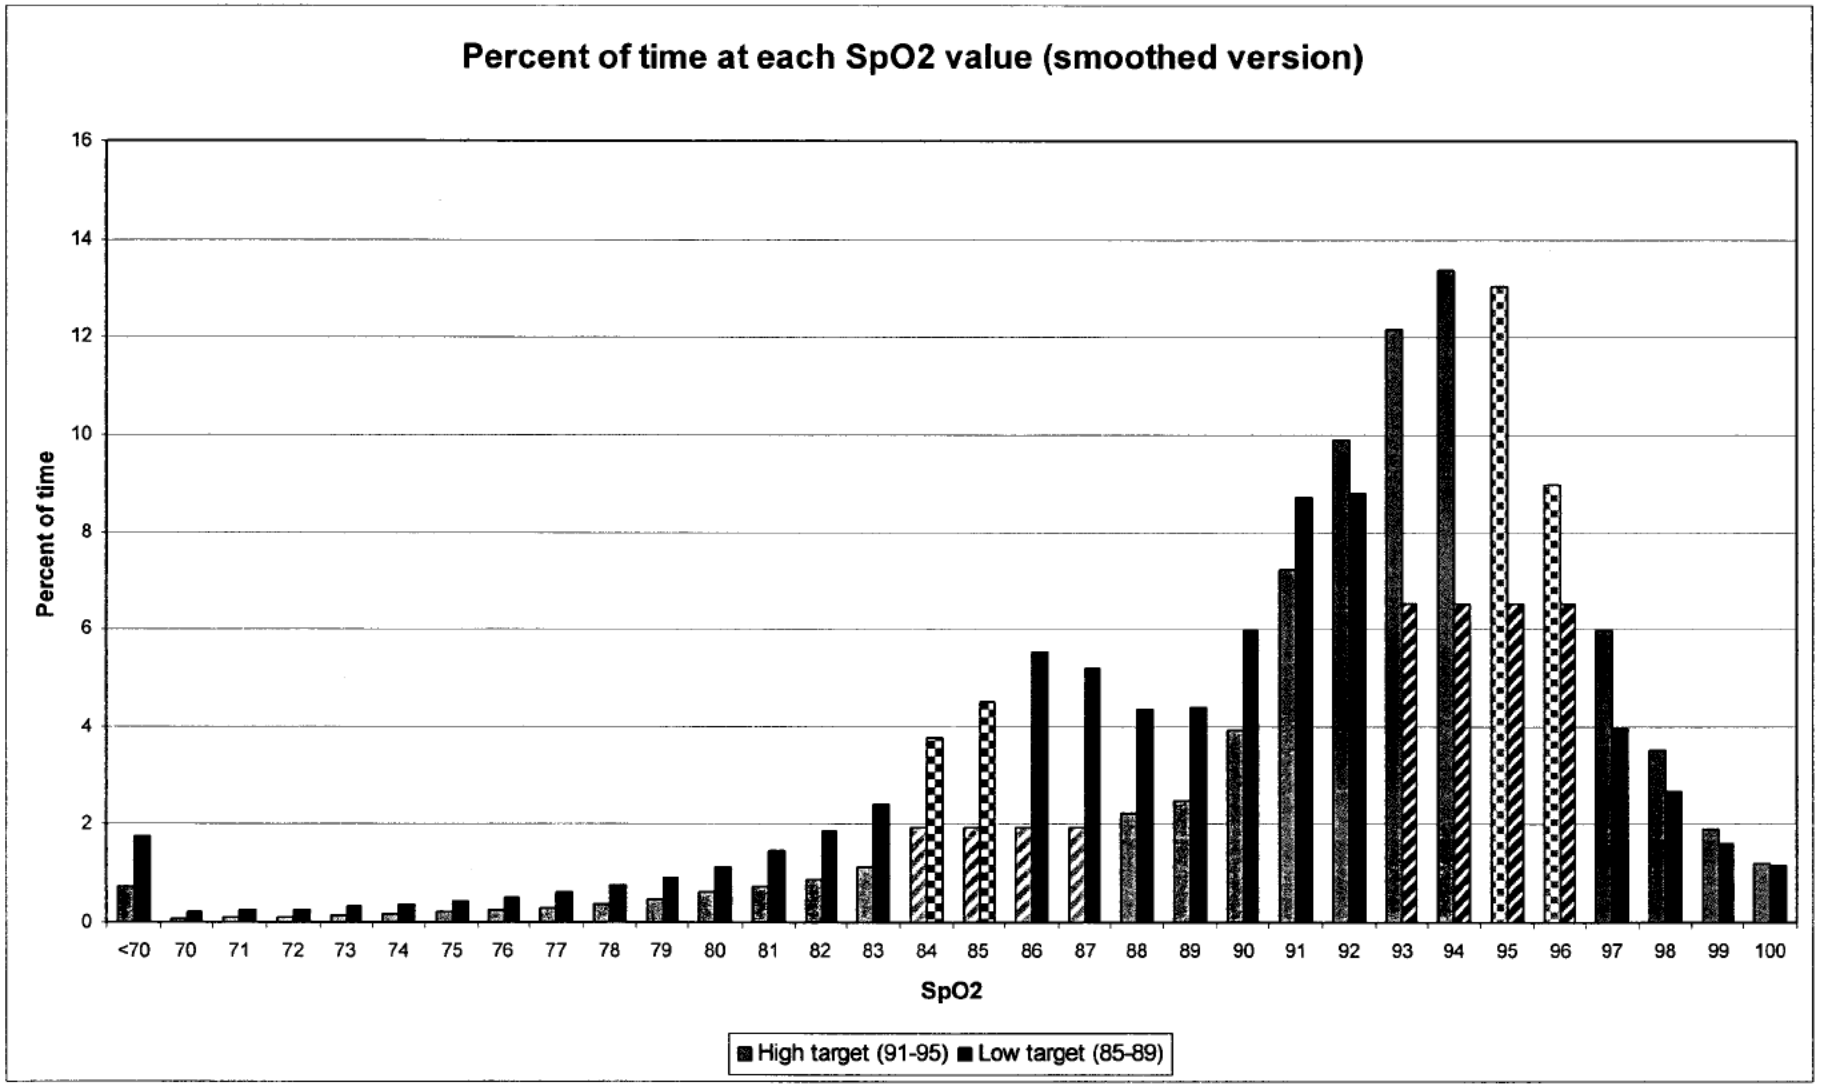
Percent of time of spent at SpO2 <84 and >96

Range	High target (91-95)	Low target (85-89)
<84	6.39	13.34
>96	12.56	9.39

The graph below displays each individual converted SpO2 value



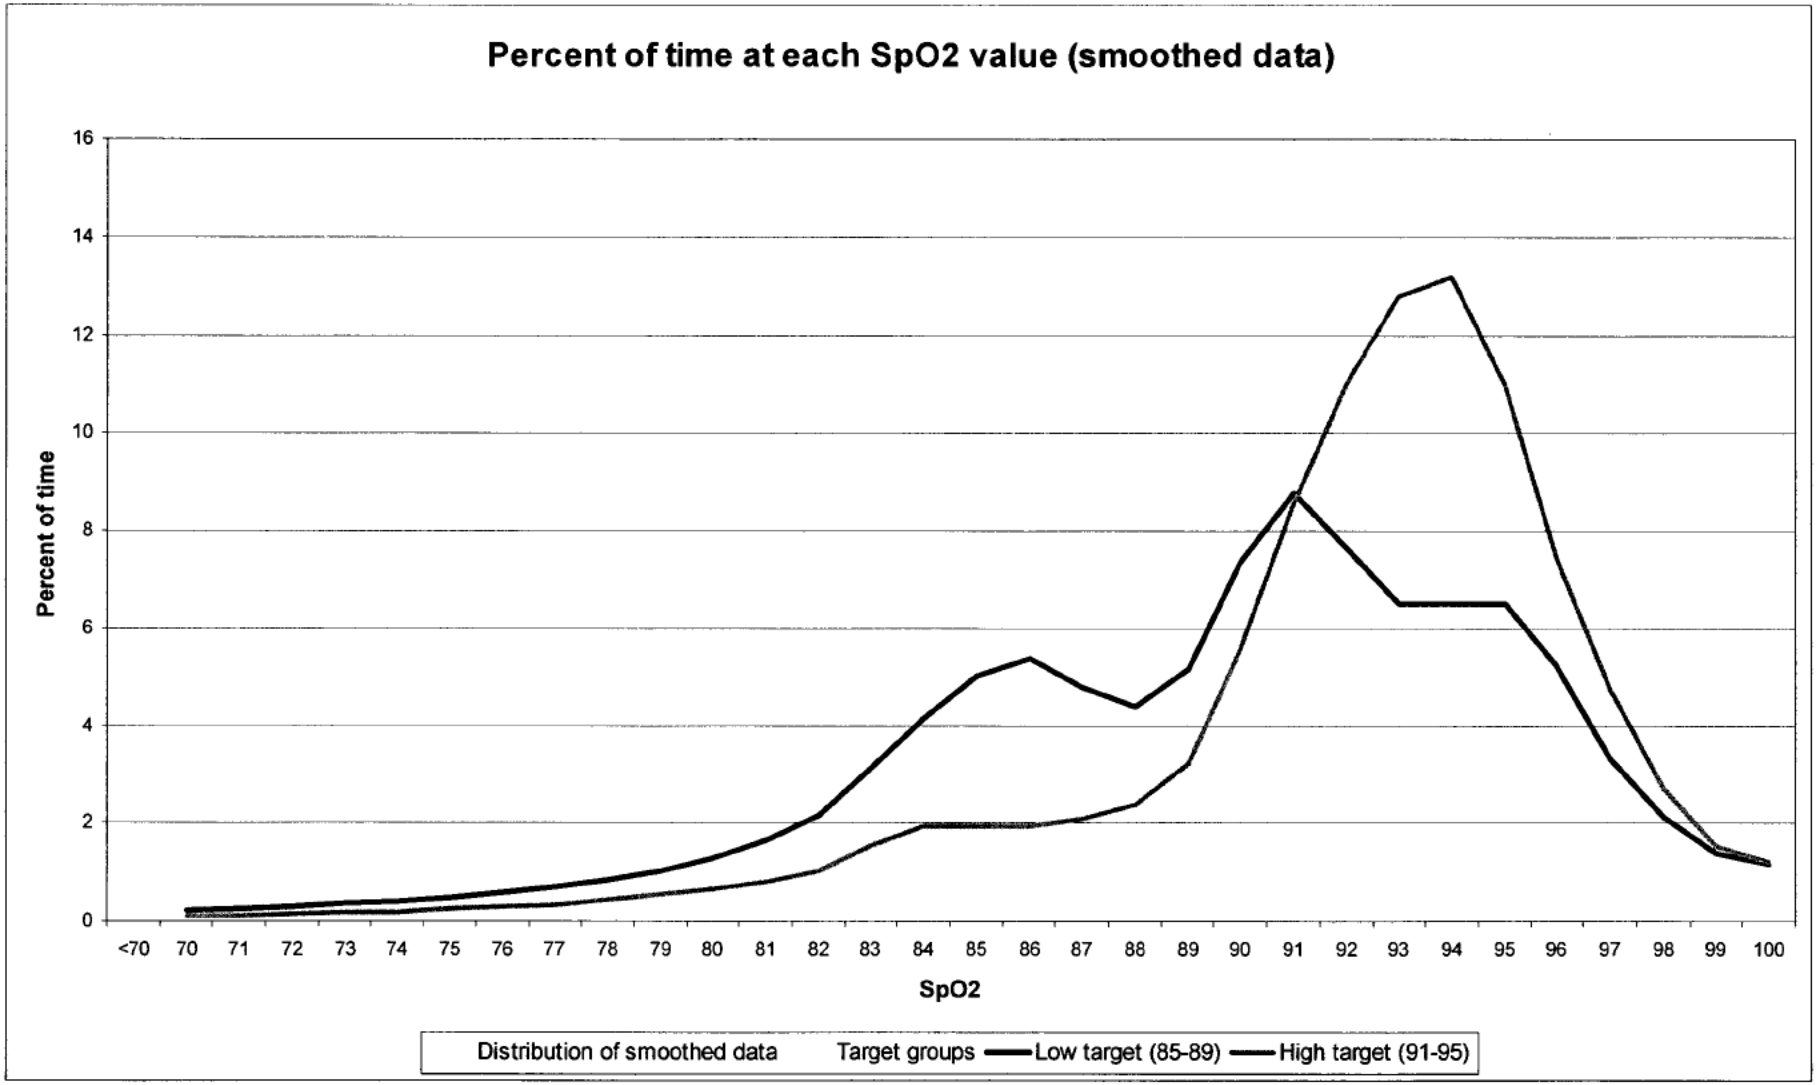
In the graph below, the converted SpO2 values have been smoothed to give a better idea of the distribution. Adjustments made to smooth the data are listed on the following page. Patterns are used to identify altered values.



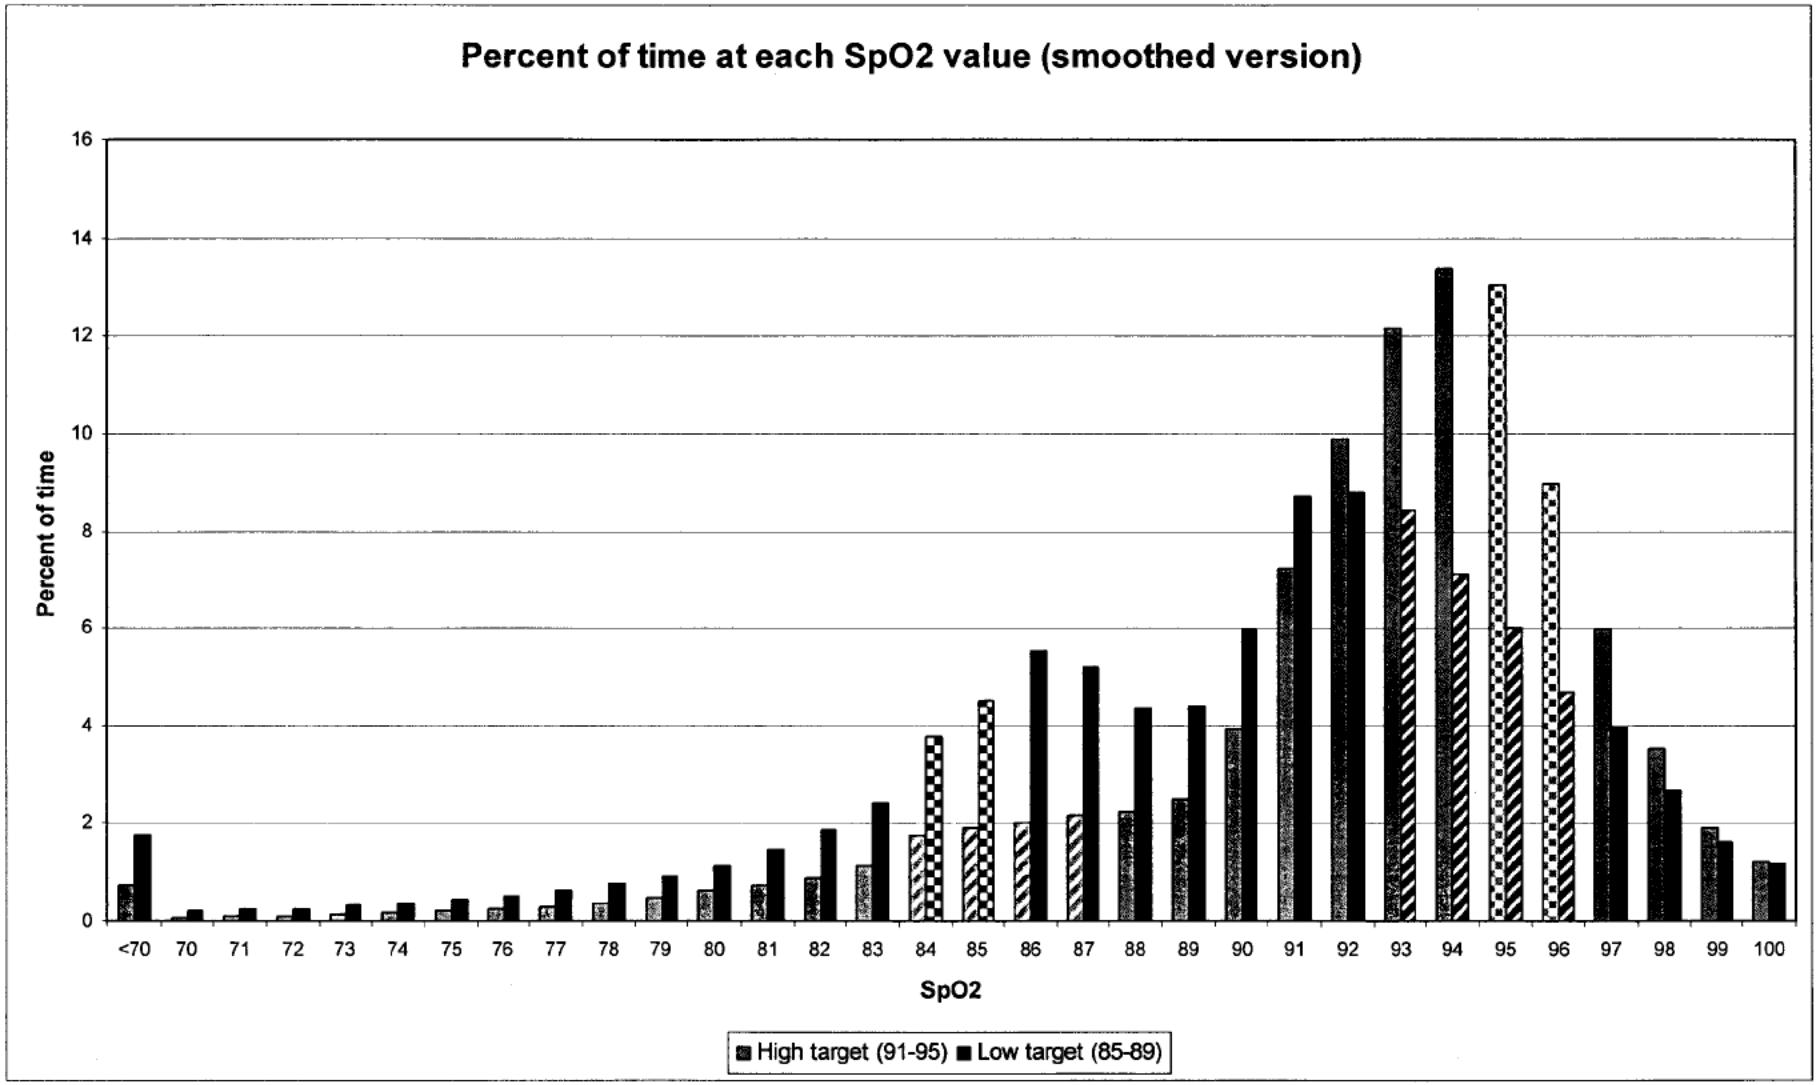
Changes made to achieve smoothing

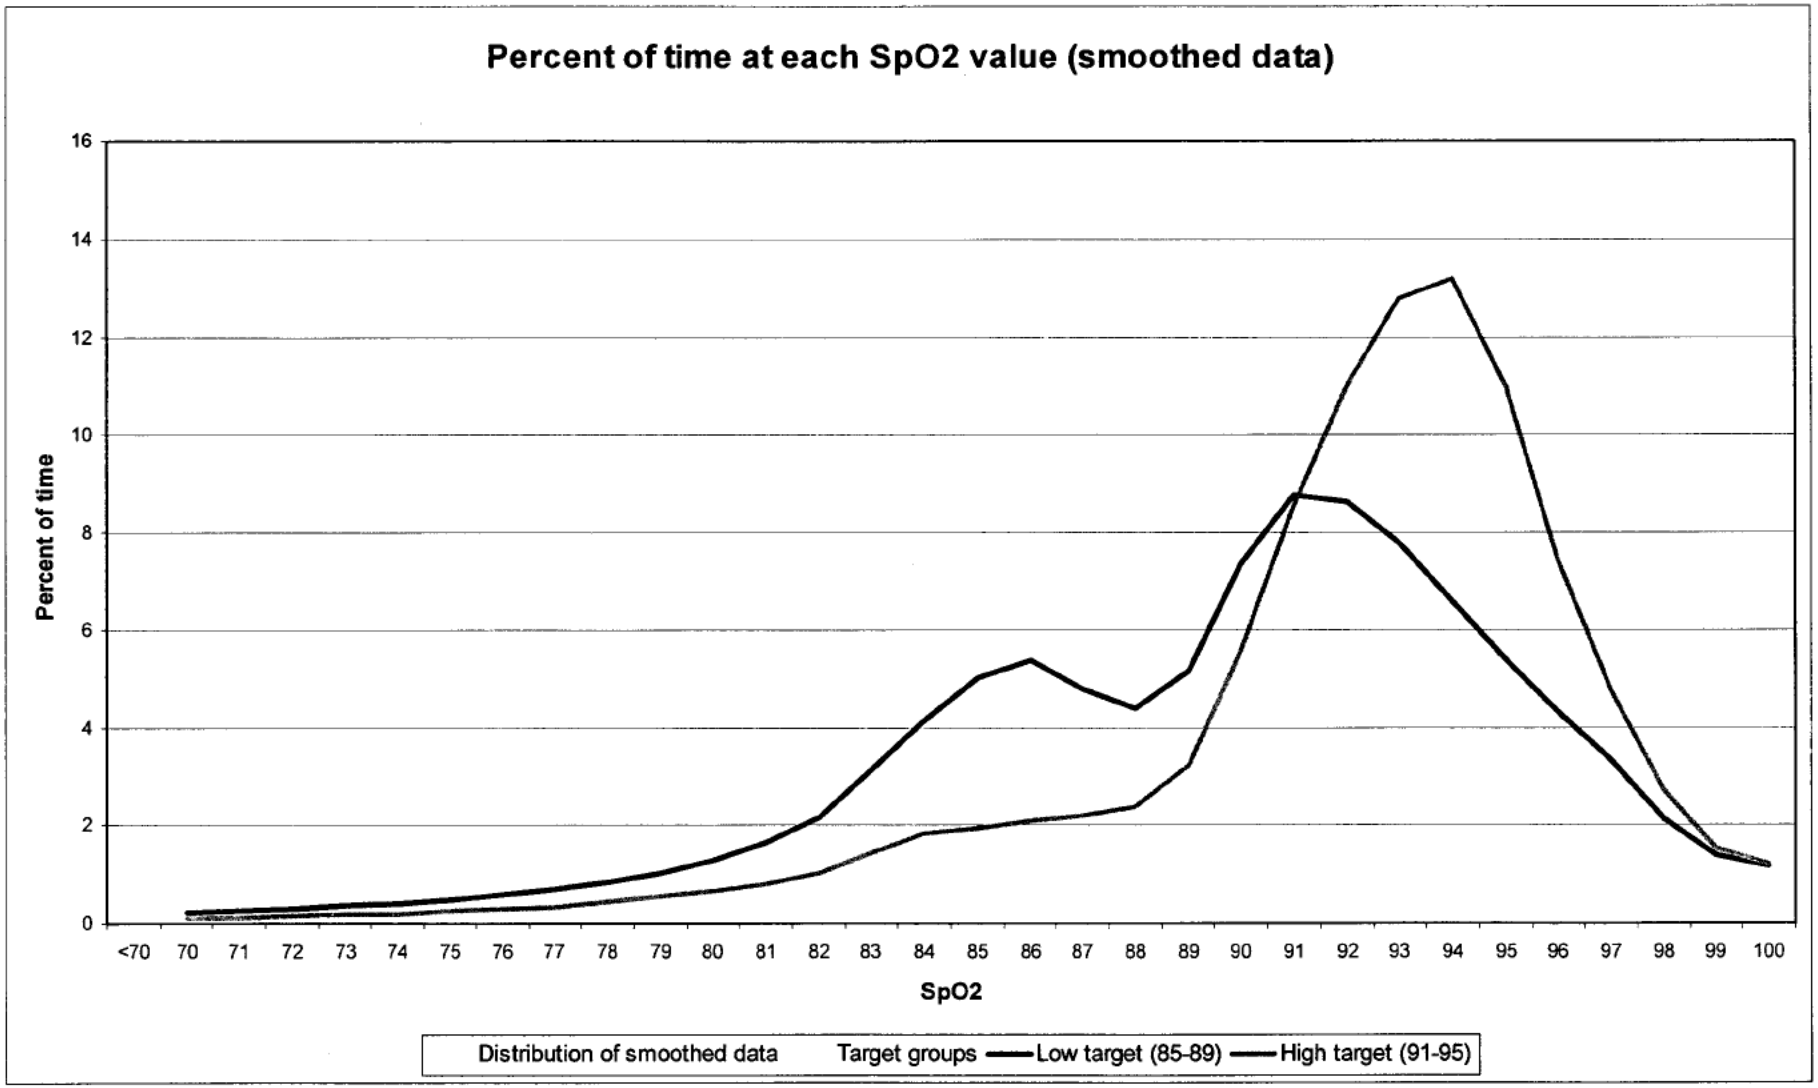
High target (91-95)	Pattern
Percent of time at converted value of 85.5 are spread evenly over 84-87	Blue diagonal stripes
Percent of time at 95 includes converted values of 95, 95.25 and half the percent of time at 95.5	Blue checked
Percent of time at 96 includes converted values of 96, 95.75 and half the percent of time at 95.5	Blue checked

Low target (85-89)	Pattern
Percent of time at converted value of 94.5 are spread evenly over 93-96	Burgundy diagonal stripes
Percent of time at 84 includes converted values of 84, 84.25 and half the percent of time at 84.5	Burgundy checked
Percent of time at 85 includes converted values of 85, 84.75 and half the percent of time at 84.5	Burgundy checked



The following two graphs are the result of some additional smoothing.





Percent of time spent in each ACTUAL SpO2 range
Days on room air only

Thanks Neil
I'd have to disagree with some of the concepts in Room Air.
Sat 98-100% in Room air could be fairly well predict PaO2. The PaO2 in room air with those saturations will never be "low" nor "high". i.e.: PaO2 of (50) 55 mmHg at low end to 65-(75) mmHg at high end. So "hyperoxemia" is not possible.
Different could be the case with those sat levels when breathing supplemental oxygen. As you know sat monitors cannot detect hyperoxemia, and is impossible to predict PaO2 form those sat levels (sat is) and infant is breathing FiO2 > 21%.
I think that to avoid hyperoxemia and ("see-saw"; i.e wide variations) is not to be interpreted as permitting or inducing hypoxemia.
I would not consider giving a healthy preemie less than 21% Oxygen to breath. As described by Rigatto, Alvaro and others hypoxic gas leads to hypoventilation and more apnea (possibly then leading to giving supplemental O2 in clinical practice and/or to "up and down" and wide variations).
Thank you
Regards
Augusto

Subject: RE: SUPPORT Conference Call
Date: Friday, December 09, 2005 8:46:57 AM

Just a reminder of the conference call scheduled for Tuesday the 13th. Please let me know, by today, if you have not received the Fed-ex package with the material for this call. It was sent on the 6th and you should have received it on the 7th.

Thank you.
Betty

Dear DSMC Members,
The DSMC conference call, to discuss the SUPPORT study, has been scheduled for Tuesday, December 13, at 2:00pm EST. To join this call please **dial the toll free number 888-396(b) (6) and enter the numeric Passcode (b) (6) (# when prompted). (The USA Toll Number is +1-210-839-(b) (6).** The leader of the call is Dr. Abhik Das. The agenda, list of participants and material to be discussed will be sent by Fed-Ex on December 6th. Please let me know if you do **not** receive this material.

Thank you.
Betty

Subject: Fwd: Valuable information from the data from SUPPORT
Date: Thursday, December 08, 2005 10:00:59 PM

Rose
I sent Augusto an email about his comment-- I think he did not mean to write that is was stopped for "poor design"-- but rather that because it was stopped would be quite a while to have data that is of course important for clinical care practices.

He just sent me these comments. Please share
BJS

Barbara
I have reviewed the data as sent by you.
If you so decide, I give my consent for you to share with PI and/or others my assessment of the data as submitted, that I evaluated and believe contains important clinical information.

Total numbers of hours analyzed: > 100,000
153 infants.

1) Saturation > 95% (High risk for hyperoxia): More than 2 times more risk in high treatment group.
36.2% of the time in high treatment group vs 14.9% of the time in low treatment group. This suggests that "choosing a higher target" exposes infants to undesired higher risk of hyperoxemia. This is clinically very important from safety concern regarding increased exposure to periods of undesired hyperoxemia.
Even though I do not have all the raw data in hours to do a detailed analysis, this information of 36.2% vs 14.9% shows in simple analysis a significant risk reduction to avoid periods of hyperoxemia by using lower O2 Sat Targets.

2) Time with Saturation levels 85-95%:
In the low treatment group, 66.2% of the time the Saturation is 85-95%
In the High treatment group this only occurs 55.2% of the time.
(Based on number of hours, this difference is also very likely to be highly significant).
If this were "an accepted range", the information lends support to the fact that

3) Time below "respective" target:
High Treatment group: 24.3% of the time below target of 91-95% Sat level; and 8.6% of the time below 85% Sat level.
Low treatment group: 18.9% of the time below 85% Sat level (or below target of 85-89% sat)

4) "Mean" O2 sat levels: I believe that using "mean" O2 levels (as shown is the last column to the right) it may be an incorrect way of analyzing the data from this study to convert it into valuable information.
These are not normal distributions. (Median, extreme values, etc may be better).

90% mean sat level in low treatment group and 92.2% mean sat level in high treatment group may be significant, but clinically that may have no value at all.

If the information that can be derived from the data you sent us is correct, then I believe the following are important:
a) There in fact appears to be a "substantial separation" between the groups.
b) If intention to treat and risks of hyperoxemia and hypoxemia are considered, the groups are different (as shown above in 1) in regards to the time of exposure to high risk of hyperoxemia. This is important information to share as is with clinicians.
Furthermore, if a Sat level less than 85% is undesirable, then 18.9% vs 8.6% of the time may be unacceptable. However, < 85% may e 83 and 84% or 70-75%. I would suggest evaluating in detail the time spent between different sat levels at low end (i.e.: 82-85% , 80-82%, 75-80% and less than 75% in both groups and compare.)

In addition to the above, there may be even more important clinical effects that could become known by completing the study.

Thank you

Augusto Sola

Hi Cindy
I will be able to talk to you hopefully later next week about SUPPORT. We are on a hold from the DSMC and will be having a meeting with them next week. Once that is done and we have a decision, I will call. Sorry that I am unable to discuss in any detail at present.
You will probably learn more from others than I am able to discuss at present.
Be well
Neil

Subject: SUPPORT Trial
Importance: High

Dear Neil,
I realize am not up on the progress of SUPPORT.
The comment from Augusta (in the email below) is very important.
If you do not mind sharing, and if Augusta's comment is true, I would like to learn what issues put SUPPORT on hold, and if the issues are relevant to US POST, BOOST, etc.
I am in Wash DC.
Email you have.
Cell: 617-529(b) (6)
I hope you are well.
Look forward to speaking with you.
- Cindy

Subject: Re: Masimo Holiday Card

Of course my study can be referenced if done appropriately.
SUPPORT has already been put on hold due to poor design (as suggested)
Thank you
Augusto

---

Hi Betty
Thanks for being patient
These are the actual files that should be sent to the DSMC. I have reread them and made some additional changes to the crucial files: ie the Response to the DSMC and the Avery Letter are not the same as the ones that were previously circulated.
Please let me know if you have any difficulty opening or sending these.
I have waited till 11:00PM Eastern Time for any further responses.
I think that we should go with these and give the DSMC time to review.
Be well
Neil

In response to the comments and concerns of the DSMC, the SUPPORT committee held a conference call Monday Nov 28th at 10:00 to 1130AM to prepare a response. This issue and the preparation of a response was then discussed by the entire NICHD Neonatal Research Network Steering Committee in a conference call held Wednesday. Nov 30th at 9:30 – 11:00 AM. This response has been reviewed by the SUPPORT Subcommittee, and subsequently by the Steering Committee, and reflects the input of all NICHD Principal Investigators.

- The DSMC made the following 2 comments in their letter regarding the SUPPORT trial. This was generated after they reviewed the oximeter data, which was corrected back to actual SpO2 values from the altered values displayed at the bedside:

1. There is a significant safety and exposure issue for the infants in the high saturation treatment group because an unacceptably high proportion of time was spent by these study subjects in the >95% range

2. There is a futility concern for this arm of the trial in that there does not appear to be substantial separation between the two high and low saturation treatment groups, and the babies are not being kept in the target range the appropriate amount of time in order to meaningfully test the oxygen saturation intervention as originally designed.

Based on these two issues, the consensus of the Committee was to recommend stopping the oxygen saturation arms of the SUPPORT trial due to safety and futility concerns.

We have responded to each of these concerns and our responses are detailed below

Response to Issue Number 1

We appreciate the concern expressed by the DSMC regarding a potential safety issue secondary to durations of SpO2 values greater than 95%.

1. Review of existing evidence and practice regarding durations of higher SpO2 values:

To date there are no prospective data which define the SpO2s experienced by the ELBW infant from birth as part of usual clinical care. Because no published studies have evaluated the effects of different target SpO2 ranges from birth on important outcomes, this was one of the principle reasons for the design and conduct of the SUPPORT trial – Oximeter Arm.

A number of studies have evaluated different alarm limits, but have not reported the actual durations of SpO2 in the various ranges. Nghiem et al in a PAS abstract this year reported that nurses caring for ELBW infants believe that an acceptable oxygen saturation range should include higher upper limits than

specified by current policy (Nghiem et al, Nursing Opinions and Practices of Oxygenation in Prematures: The NOPOP Study PAS #3415, 2005). The study by Hagadorn reported as a late breaker at the PAS last year (Hagadorn et al, Actual vs Intended Pulse Oxygen Saturation (SpO2) in Infants <28 Weeks Gestation. PAS 2004, Attached) did report on the experience of monitoring the actual SpO2 for 72 hours in the first 4 weeks of life in 78 ELBW infants. They reported that the "lower limits of intended ranges at study centers varied between 83-92%, upper limits 92-98%. Infants were monitored for a median of 70 hours (25th-75th percentiles 67-71 hr) during each of the first 24 weeks. Overall median SpO2 for infants on supplemental O2 during the first 4 weeks was 95% (25th-75th percentiles 91-97%; range of study center medians 91-96%. Centers ranged between 16-71% compliance with their individual intended SpO2 range. Most noncompliance was above intended range." In comparing the SUPPORT data evaluated to date by the DSMC, it is of interest that the mean SpO2 in the 2 Oximeter arms is 90% and 92%, with medians of 92% and 94%, all of which are below that reported by Hagadorn et al (median=95%).

The 2 other relevant trials, STOP-ROP and BOOST, both enrolled infants of > 32 weeks postmenstrual age (PMA), and maintained 2 levels of SpO2, 89% to 94% and 91 to 94% versus 95% to 98% and 96% to 99%, by administration of oxygen. These studies achieved reasonable separation, but did demonstrate substantial overlap of the intended ranges (estimated to be 50% or greater, D Phelps, PI for STOP-ROP). It is important to note that these studies were testing two ranges both of which were higher than the lower range of the SUPPORT trial (85% to 89%) and were treating infants who, for the most part, had recovered from their acute disease. In the BOOST trial 70% of the enrolled infants were < 28 weeks of age at birth (all of SUPPORT is < 28 weeks), 32 weeks PMA at enrollment, and required oxygen at enrollment (Askie et al, New England Journal of Medicine. 2003; 349(10):959-967). The STOP-ROP trial enrolled infants with pre-threshold ROP at a PMA of 35.4 + 2.5 weeks of age (Phelps et al, Pediatrics. 2000; 105(2):295-310). These trials then gave the higher SpO2 range infants additional oxygen to increase their SpO2 to the desired range. STOP-ROP reported that the infants in the high range had an SpO2 > 95% for > 97% of the monitored time. These studies found an overall increase in pulmonary morbidity in the higher SpO2 range infants.

Examination of oximeter data from one of the NRN sites (Case Western, Walsh et al) obtained for a current ongoing study evaluating infants similar to those enrolled in SUPPORT, and managed with conventional oximeters, revealed that for the 9 infants for whom results were available that the percentage of time with and SpO2 > 95% was > 50%.

2. Impact of SUPPORT oximeters algorithm on sat values:

The oximetry algorithm that was designed for the SUPPORT trial is such that re-conversion of the altered oximeter values does not result in a discrete SpO2 number for every displayed value. SpO2 values, of 93%, 94% 95% and 96% will all be reconverted to a single value. In the 85% to 89% arm, values of 84%, 85%, 86% and 87% will be reconverted to a single value of 84%. This is a

result of having the displayed values return to non-skewed SpO2 values at < 84% and > 96%, a safety design felt to be important by all involved in this trial (See Attached file USCD Conversion). Thus the percentages reported to the DSMC for some of the ranges that include these values were not an accurate representation of the true values. However all values > 96% and < 84% are actual and do not require any conversion.

Percent of time of spent at SpO2 < 84% and > 96%
(RTI, Dec 2, 2005)

Range **Assigned**	High target (91-95)	Low target (85-89)
< 84%	8.30	14.05
> 96%	21.45	15.47

In the current SUPPORT study, an initial analyses utilizing only unaltered SpO2 values as shown above , ie those below 84% and above 96%, have shown that one arm had an SpO2 > 96% for 15.47% versus 21.45% of the time for the comparison arm, and the duration of an SpO2 < 84% was also different at 14.05% versus 8.30%. The values for SpO2s > 96% using unaltered data suggests that the SUPPORT trial to date has, if anything, reduced the duration of higher oxygen saturations.

In addition, analyses using only actual SpO2 demonstrate that the infants in this trial who are receiving supplemental oxygen are spending approximately 70% of the time with a true SpO2 value between 84% and 96%. We believe that this is information is very encouraging.

3. Impact of inclusion of data from periods in room air on saturation distributions:

As part of the SUPPORT trial, we collect information about inhaled oxygen concentration 3 times a day for the first 14 days and daily thereafter. We believe that an improved documentation of the times when infants are actually on room air will allow us to determine the saturations during actual oxygen exposure. At the present an infant is considered to be receiving supplemental oxygen if he/she requires oxygen for greater than 2 hours in a day. This results in infants being categorized as receiving supplemental oxygen for significant periods when they are actually in room air. This would result in durations of SpO2 greater than 95% that were felt to be modifiable and reported as such when in fact there is no effective treatment for such elevated SpO2s. In addition, we do not know if such SpO2s on room air are associated with any morbidity. From the SUPPORT study data analyses to date we know that study infants in room air have SpO2s > 95% for 46% to 69% of the time. By using only information for actual SpO2 values of 96%, we have determined that the infants in the 91%-95% group had a duration at an SpO2 of 96% of 6.68%, and a total duration of 96% or greater of 28.13%.

In view of this design, we would suggest that all future interval analyses for safety examine the ranges of <84% and >96% and consider those ranges for review of low and high durations of SpO2.

We believe that the SUPPORT trial will actually define the periods of time that ELBW infants spend with different ranges of SpO2, and that it is essential to collect this information. In addition, as our findings indicate a lower true percent of the time at SpO2 values >95%, and lower median SpO2 values than has previously been reported, we are in fact, reducing the time with high SpO2 values compared to usual care. The SUPPORT trial carefully evaluates risks, and we will be evaluating group differences for all important short and long term outcomes.

The SUPPORT trial methodology actively encourages all caretakers to keep SpO2 < 96% by having alarm limits set at 85% and 95%. These limits were utilized because it was felt that these represented current practice, and there are no studies which have provided information regarding durations of SpO2 below 85% and subsequent outcomes. While we have had substantial discussion about decreasing the lower alarm limit to below 84%, we are reluctant to make such a recommendation in view of the likely resultant increases in durations of SpO2 below 84%. Nevertheless, our results to date suggest that we have decreased the expected percent of time > 95%, and in one group the value of 14% may be as low as is achievable in an actual clinical environment given the evidence provided by Hagadorn et al and Nghiem et al. In addition a preliminary analysis of the FiO2 exposure of the 2 oximeter groups has demonstrated that the 85% - 89% group have a substantially decreased exposure to oxygen compared to the 91% - 95% group. (See below)

We believe the SUPPORT study will define the distribution and durations of pulse oximetry values among premature infants in highly staffed, dedicated academic centers, and among infants randomized to two different target ranges. For this reason alone, the SUPPORT trial will be very valuable. All of the procedures outlined below in response to your second concern will also allow us to further increase the percentage of time that the infants are in the maximally altered SpO2 ranges which we believe will further increase separation of these groups.

Response to Issue Number 2

There is concern that we have not achieved adequate separation by the current oximeters and study personnel.

1. As described above, the results of additional analyses performed in response to the concerns of the DSMC show differences in the durations of low and high SpO2s between the 2 oximeter groups, but lesser differences in the narrower target ranges. A careful analysis of the most recent converted values demonstrates that the cumulative time spent with an SpO2 of 90% or less is 24.0% (91% - 95%) versus 39.5% (85% - 89%,See Percent of time at each SpO2

value 12-2-05.doc). In addition, the 91% -95% group spend 40% of the time in that narrow range which may represent the achievable target duration for the narrow target range. The 85% - 89% oximeter group spends 18% of the time in their narrow target range. One obvious reason for this difference is that when the 91%-95% group exceeds the high end of the range, the oximeter alarms, whereas this does not occur for the high end of the lower range infants.

We have now had an opportunity to review the actual FiO2 exposure of the 2 oximeter groups and that analysis is attached (Daily FiO2 for first 14 days.doc). This analysis has shown that the infants in 85% - 89% group spend approximately 10% more time in room air in the first 14 days than infants in the 91% - 95% group (35.5% vs 26.6%). We do not at the present time have any comparative data for similar populations of ELBW infants, and the actual significance of these differences will only become apparent when the trial is completed.

2. We do acknowledge that it would be desirable to increase the percentage of time in the narrower target range and towards this end would propose the following changes to SUPPORT:

A. We will **change the high alarm to 94% to further assist in keeping the 85%- 89% group more in target and reduce the durations of SpO2 > 95% in the 91% - 95% group**. This change should improve our time in the narrow target ranges and further separate our 2 oximeter groups. For the 91%-95% group, at present when the study oximeter reads greater than 92%, the actual SpO2 is at 95%. This will result in more frequent high alarms for this group, the result of which will be to reduce the durations of higher SpO2s.

B. We will require **documentation that the oximeters alarm limits are set and functional as per protocol every 4- 6 hours**. We have found that in some units the high alarms are being turned off, and thus believe that such documentation will greatly assist in decreasing the actual time that the SpO2 is > 96%. This task will be assigned to the most appropriate personnel in each unit, which may include bedside or research nurses or respiratory therapists, and this procedure is already being done in many NRN units.

C. We will immediately initiate a **change in our data collection for FiO2 to ensure that subsequent interval reports more accurately reflect saturations measured while on oxygen therapy and exclude saturations of infants in room air.** We will change the data form to indicate that the infant was either in oxygen for the entire 24 hours, and if not, will provide a more accurate estimate of the true time in oxygen, and we will continue with this form of data collection for the entire time that the infant is receiving oxygen. In the current protocol we collect such information 3 times a day for the first 14 days only and then daily thereafter. We believe that more frequent and extended documentation will allow us to determine more accurately the actual time that an infant is in room air. At the present the infant is considered to have spent a day in oxygen if he/she requires oxygen for greater than 2 hours. This results in infants being categorized

in oxygen for significant periods when they are in room air. While in room air, we cannot manipulate the SpO2, and thus knowledge of the true time in oxygen will produce a more accurate representation of oximetry results that are subject to care interventions.

D. We will initiate **further training and in-service, and a change to the protocol to stress the importance of keeping the SpO2 alarms functional and at the limits of 85% and 94%**. In the past these were guidelines, and we will now change the study manual and protocol to indicate these limits are now set by protocol and that violations will be documented. We will encourage all caretakers to aim for an SpO2 value of 90% and make every effort to educate caretakers to make smaller adjustments in FiO2 and ensure that the infant is maintained between the 87% to 93%, the range with the maximal separation of the study oximeters. We will further facilitate the use of the 2 hour and 12 hour histograms showing the infants' actual ranges to provide feedback to the caretakers regarding the percentage of time in the target ranges.

E. We will develop **guidelines for managing desaturations such that the increase in oxygen is proportional to the desaturation**. More modulated increases in oxygen during these desaturation events will minimize overshoot and the potential of high SpO2 values. We would hope that such changes – ie increasing the FiO2 in steps of 5% as opposed to much larger increases will decrease the resultant overshoots creating the high SpO2 values. This will be included in the revised manual of operations.

F. **We will place bedside cards to indicate the desired target range**.

G. We will **initiate compliance monitoring visits coordinated by RTI to visit random sites**. These visits had been planned, but had not yet been initiated. The teams will consist of a member of RTI and a study coordinator, and they will review the adherence to the protocol and any other relevant issues.

H. We would recommend that at a minimum, **the unblinded oximetry data be reviewed again after an additional 100 to 150 infants have been enrolled in this trial.**

We thank the DSMC for their thoughtful concerns. We trust that our plans to move forward with the SUPPORT trial are acceptable to the DSMC. We are anxious to initiate the above changes, seek IRB approvals and re-activate this trial.

Gordon Avery, M.D.
Chairman of the Data Safety Monitoring Committee
NICHD Neonatal Research Network

Dear Dr. Avery,

The SUPPORT Trial Subcommittee and the NICHD Network Steering Committee have reviewed in detail the concerns of the Data Safety Monitoring Committee. We are appreciative of the diligence and thoughtfulness that went into these concerns and we have carefully considered the comments made by the Data Safety Monitoring Committee with respect to both the issue of patient safety and the question of futility relative to the separation of the infants in the two oximetry arms of the trial.

We are very mindful of the need to protect patient safety and toward this end have reviewed the current experience relative to exposure of current ELBW infants to saturations above 95%. There is little information regarding this issue in the literature. We have quoted what we believe to be the relevant recent experiences, including the Network experience with exposures to higher SpO2 ranges. In addition we had asked RTI to provide us with unaltered oximetry data which allows us to look at information for oxygen saturations of 97% or greater and less than 84%, as these values were not altered by the algorithm in place for the study. We also compared the mean and median values of the SpO2 seen in the SUPPORT trial to date with those reported by Hagadorn et al, the only other report that contains such information. This information suggests that our current SpO2 exposures, especially to SpO2 values of 97% and above, for infants within the SUPPORT trial are probably less than is currently being experienced outside of the trial, both from the Network experience and in the general practice of neonatology for the ELBW infant. In addition our median SpO2 values for both of our oximetry groups are lower than those reported by Hagadorn et al. An initial evaluation of the FiO2 data does demonstrate that the 85%-89% group requires oxygen for 10% less overall duration in the first 14 days than the 91%-95% group, further indicating that these groups are being separated in their clinical management.

We agree that we should aim for greater separation between the oximetry groups, and are pleased that we are seeing some differences on SpO2 and FiO2 exposures between the groups. There is less separation in the target ranges than we desired, and I have detailed our responses to each of the

DSMC's concerns in the attached review. We believe that with these changes to the Protocol and Manual of operations and additional in-service at the sites coupled with intermittent site visits, that we will attain an even greater SpO2 separation in all ranges, and differential oxygen exposure for our 2 study groups. We would also like to recommend a re-evaluation of this data after an additional 100-150 infants have been enrolled.

We thank you and your committee for your careful review and suggestions. We hope that our responses are appropriate and that we may be allowed to continue this important trial

Sincerely,

Neil N. Finer, M.D.
Principal Investigator on behalf of the SUPPORT Subcommittee

LATE BREAKER ABSTRACT SUBMISSION FORM

Abstracts and Payment must be RECEIVED by March 1, 2004

~ Abstracts must be submitted electronically using this form.
~ Abstracts, inclusive of title, authors, institutions, and graphs/tables, must fit in a 6.5 inch x 4 inch space between the two lines (appx. 2,600 characters). Use a font no smaller than 10 pt.
~ You must complete all information and include payment ($50 US) for your abstract to be considered.

Actual vs Intended Pulse Oxygen Saturation (SpO2) in Infants <28 Weeks Gestation

J Hagadorn [1,2], A Furey [1], TH Nghiem [1], S Greene [1], E Abban [1], J Cho [1], P Shrestha [1], A Vora [1], M Landa [2], C Schmid [2], P Hibberd [2], CH Cole [1] and The AVIOx Study Group. [1]Div Newborn Med and [2]Div of Clin Care Research, Tufts-New England Med Ctr, Boston, MA.

Background: Detailed data are not available regarding the actual versus intended SpO2 in infants born <28 weeks gestation (extremely premature newborns, EPNs) in the neonatal period during routine care. **Objective:** To document actual SpO2 in EPNs in the first 4 weeks of life during routine care and compare to the level recommended by local policy/guideline. **Design/Methods:** EPNs <96 hours old were enrolled in a prospective multicenter cohort study. Oximetry data were collected every 2 seconds with masked signal-extraction oximeters for 72 hours in each of the first four weeks of life. Data were compared to SpO2 range prescribed by local institutional policy. **Results:** 14 centers from 3 countries enrolled 78 infants with mean birth weight 863 g (SD 208 g) and mean gestational age 26 wk (SD 1.4 wk). Lower limits of intended ranges at study centers varied between 83-92%, upper limits 92-98%. Infants were monitored for median of 70 hours (25^{th}-75^{th} percentiles 67-71 hr) in each week. Overall median SpO2 for infants on supplemental O2 during the first 4 weeks was 95% (25^{th}-75^{th} percentiles 91-97; range of study center medians 91-96). Centers ranged between 16-71% compliance with intended SpO2 range. Most noncompliance was above intended range. **Conclusions:** Compliance with intended SpO2 range during routine care varied substantially among participating centers, and was generally poor regardless of intended level. These data will assist quality improvement and education efforts, and will aid planning of prospective randomized trials examining level of oxygenation. **Disclosure:** Funded by the SPR Student Research Program; Fight for Sight/Prevent Blindness America; The Tufts-NEMC Research Fund; GCRC/Natl Center for Research Resources MO1-RR00054, and NEI K23 EY/HD00420. Oximeters provided by Masimo Corp.

Briefly describe the reason why the December deadline could not be met:
Study still in progress at December deadline, with only about 60% of enrollment achieved.

Oxygen-Saturation Targets and Outcomes in Extremely Preterm Infants

Lisa Maree Askie, Ph.D., M.P.H., David John Henderson-Smart, Ph.D., M.B., B.S., Les Irwig, Ph.D., M.B., B.Ch., and Judy Margaret Simpson, Ph.D.

ABSTRACT

BACKGROUND

Physiological studies have shown that chronic hypoxemia may occur in preterm infants who require supplemental oxygen for extended periods and that this hypoxemia may contribute to poor growth and development. Anecdotal reports and uncontrolled observational studies have suggested that a higher oxygen-saturation range may be beneficial in terms of growth and development.

METHODS

We conducted a multicenter, double-blind, randomized, controlled trial involving 358 infants born at less than 30 weeks of gestation who remained dependent on supplemental oxygen at 32 weeks of postmenstrual age. They were randomly assigned to a target functional oxygen-saturation range of either 91 to 94 percent (standard-saturation group) or 95 to 98 percent (high-saturation group); this target was maintained for the duration of supplemental-oxygen therapy. The primary outcomes were growth and neurodevelopmental measures at a corrected age of 12 months.

RESULTS

There were no significant differences between the groups in weight, length, or head circumference at a corrected age of 12 months. The frequency of major developmental abnormalities also did not differ significantly between the standard-saturation group and the high-saturation group (24 percent and 23 percent, respectively, P=0.85). There were six deaths due to pulmonary causes in the high-saturation group and one such death in the standard-saturation group (P=0.12). The high-saturation group received oxygen for a longer period after randomization (median, 40 days vs. 18 days; P<0.001) and had a significantly higher rate of dependence on supplemental oxygen at 36 weeks of postmenstrual age and a significantly higher frequency of home-based oxygen therapy.

CONCLUSIONS

Targeting a higher oxygen-saturation range in extremely preterm infants who were dependent on supplemental oxygen conferred no significant benefit with respect to growth and development and resulted in an increased burden on health services.

N Engl J Med 2003;349:959-67.

Improved survival of extremely preterm infants[1] has been associated with an increase in the incidence of chronic lung disease of infancy,[2] currently defined by a continued dependence on supplemental oxygen at 36 weeks of postmenstrual age.[3,4] This increased incidence has become a major clinical challenge, since chronic lung disease has serious health consequences, including poor growth,[5,6] neurologic impairment,[5,7] and pulmonary sequelae.[5,8] These and other factors may account for the higher reported health care costs for these infants than for infants who do not have chronic lung disease.[9]

Physiological studies have shown that infants with chronic lung disease (also known as bronchopulmonary dysplasia) have higher rates of oxygen consumption than infants without chronic lung disease,[10] as well as lower base-line oxygen-saturation levels, leading to more frequent episodes of desaturation.[11,12] In addition, observational studies have suggested that preterm infants who receive greater levels of oxygen supplementation, with either a longer duration of treatment or a higher target blood oxygen level, have improvements in sleep patterns,[13,14] growth, and neurodevelopmental outcomes.[15,16] Because of the uncontrolled nature of the studies, it is not known whether these associations are causal.

A policy of routine targeting of higher oxygen-saturation levels in preterm infants might result in some substantial burdens for the health care system and for parents, by increasing the duration of oxygen therapy in the hospital and the frequency of the need for home-based oxygen therapy. Despite some potential costs and the lack of evidence of long-term benefits, such policies are increasingly being implemented in clinical practice.[17,18] Data from randomized, controlled trials are lacking,[19,20] and the question of the most appropriate oxygen-saturation levels for preterm infants who require supplemental oxygen remains controversial.[21-23]

We conducted the randomized, multicenter Benefits of Oxygen Saturation Targeting (BOOST) trial to determine whether maintaining the oxygen saturation at a level higher than the standard range in extremely preterm infants with a long-term dependence on supplemental oxygen improves growth and neurodevelopmental outcomes. Secondary aims were to determine whether the higher oxygen-saturation levels had other beneficial or adverse physical or psychosocial effects on infants or parents.

METHODS

CRITERIA FOR ELIGIBILITY

Infants born at less than 30 weeks of gestational age (determined on the basis of the first day of the mother's last menstrual period, prenatal ultrasonography, or both or, if these data were not available, postnatal clinical assessment) who remained dependent on supplemental oxygen (delivered by any method and at any level) at 32 weeks of postmenstrual age were eligible for enrollment. Dependence on supplemental oxygen at 32 weeks of postmenstrual age, rather than 36 weeks, was used as a criterion for inclusion because it was current clinical practice to choose between the standard target range for oxygen saturation and a higher target range at this point in the infant's life. Criteria for exclusion before randomization included major congenital abnormalities, major surgery or a severe intracranial disorder diagnosed before 32 weeks of postmenstrual age, and a multiple birth in which three or more infants were eligible. The protocol allowed for infants from multiple gestations resulting in two eligible infants to be assigned to the same treatment.

The institutional ethics committees of the eight tertiary perinatal enrollment centers participating in the study approved the trial protocol, and written, informed consent was obtained from a parent or guardian of each eligible infant. Infants were enrolled between September 1996 and September 2000.

INTERVENTION AND BLINDING

Infants were randomly assigned to a target oxygen-saturation range of either 91 to 94 percent (standard-saturation group) or 95 to 98 percent (high-saturation group), as measured with a pulse oximeter (model N-3000, Nellcor) whose algorithm assesses functional oxygen saturation.[24] Randomization was stratified with the use of a dynamic balancing method[25] to ensure a balance of treatment-group assignments within each stratum defined according to hospital, singleton or multiple birth, and gestational age (22 to 27 weeks or 28 to 29 weeks). Central telephone randomization ensured concealment of the treatment-group assignments.

To make sure that the treatment-group assignments were not revealed, the infants who underwent randomization were assigned a specific study oximeter, which after the calculation of the infant's

oxygen-saturation level in the usual manner, was adjusted to display a value 2 percent higher than the actual saturation in infants in the standard-saturation group or 2 percent lower than the actual saturation in infants in the high-saturation group. Staff members and parents were then asked to target the range of 93 to 96 percent for the infant's oxygen saturation, so that they remained unaware of the actual ranges being targeted. Caregivers were aware that they were using adjusted oximeters and that they were participating in a trial, but they were not aware of the offset level of the individual oximeter. Double-blind targeting of the assigned saturation range was maintained for the duration of the infant's oxygen therapy either in the hospital (in both the enrollment center and other hospitals if necessary) or at home.

Dependence on supplemental oxygen was defined by the continuing need for oxygen therapy in order to maintain the double-blind target oxygen-saturation range of 93 to 96 percent, as measured by the assigned study oximeter. The frequency of monitoring of the saturation (continuous or intermittent), the settings for limits that were to trigger alarms, and the criteria for titrating the amount of ambient oxygen delivered or for ceasing delivery were determined by the attending clinicians and were not specified by the trial protocol.

ADHERENCE TO THE PROTOCOL

Compliance with the double-blind target oxygen-saturation range of 93 to 96 percent was assessed with the use of twice-weekly downloading of each infant's oxygen-saturation data, and a report on the distribution of the double-blind saturation levels was placed in the case notes. Clinicians and parents were allowed to violate the protocol either temporarily or permanently if they believed that the infant's condition warranted high-saturation oxygen therapy — for instance, because of serious intercurrent illness, as treatment for prethreshold retinopathy of prematurity, or during surgery.

PRIMARY OUTCOMES

The primary outcomes assessed at a corrected age of one year (the chronologic age plus the number of weeks of prematurity) included growth, in terms of the mean weight, the mean length, the mean head circumference, and the proportion of infants with a weight below the 10th percentile,[26] and the presence of a major developmental abnormality, defined as blindness, cerebral palsy, or a score on the revised Griffiths Mental Developmental Scales that was more than 2 SD below the mean (general quotient, <77).[27] Blindness was defined as a visual acuity in both eyes of less than 6/60.[28] Cerebral palsy was diagnosed if the child had nonprogressive motor impairment characterized by abnormal muscle tone and a decreased range or decreased control of movements, accompanied by neurologic signs.[29]

SECONDARY OUTCOMES

The secondary outcomes included the effect of the treatment-group assignment on the duration of oxygen therapy, the duration of assisted ventilation and of the hospital stay, and the frequency of home-based oxygen therapy. Parental stress and parent–infant interaction were assessed by means of validated scales (the Edinburgh Postnatal Depression Scale,[30] the Infant Temperament Questionnaire,[31] the Toddler Temperament Scale,[32] the Parenting Stress Index, Short Form,[33] and the Impact-on-Family Scale[34]). Retinopathy of prematurity was assessed by routine ophthalmic examinations at two-week intervals from enrollment until the resolution of retinopathy, with grading according to the International Classification of Retinopathy of Prematurity.[35] Reports by the parents on the use of health services and rehospitalizations during the first year of life were obtained through quarterly telephone contact by the research nurses, and rehospitalizations were confirmed through a review of the medical records. Causes of death were classified according to the codes of the *International Classification of Diseases, Ninth Revision*,[36] and confirmed on the basis of the hospital discharge summary, a postmortem examination report, a coroner's report, or a death certificate.

STATISTICAL ANALYSIS

All data analyses were performed according to the intention-to-treat principle. For continuous data, the treatment effect was calculated by subtracting the value for the standard-saturation group from the value for the high-saturation group, with results for normally distributed data presented as means ±SD and results for non–normally distributed data presented as medians with interquartile ranges. Differences between the two groups were assessed with the use of Student's t-test or the Mann–Whitney U test and are expressed as mean or median differences, respectively, with 95 percent confidence in-

tervals. For categorical data, the chi-square test was used, and the treatment effects are expressed as relative risks in the high-saturation group as compared with the standard-saturation group, with 95 percent confidence intervals. For analyses involving small numbers of events, Fisher's exact test was used, and exact confidence intervals were calculated for odds ratios, as approximate relative risks. All P values are two-sided and have not been adjusted for multiple testing or for correlation between the outcomes in siblings, since only 25 pairs of siblings were included (a total of 50 infants), representing 14 percent of the infants, and they were distributed approximately equally between the two groups.

The required sample size was calculated to ensure detection of clinically important effects on the primary outcomes: a reduction from the base-line estimate of 47 percent to 30 percent in the proportion of infants with a weight below the 10th percentile at a corrected age of 12 months, and a reduction in the frequency of major developmental abnormalities from 23 percent to 12 percent.[37] To achieve 80 percent power with a two-sided alpha level of 0.05 and a 1:1 ratio of infants in the two groups, approximately 150 infants were required in each group.

Table 1. Base-Line Characteristics of the Infants and Mothers.*

Characteristic	Standard-Saturation Group (N=178)	High-Saturation Group (N=180)
Birth weight — g	918±229	916±231
Gestational age at birth — wk	26.6±1.7	26.5±1.6
<28 Wk of gestation at birth — no. (%)	124 (70)	132 (73)
Male sex — no. (%)	92 (52)	97 (54)
Singleton birth — no. (%)	133 (75)	129 (72)
Born in tertiary care center — no. (%)	163 (92)	172 (96)
Surfactant treatment — no. (%)	138 (78)	137 (76)
Patent ductus arteriosus — no. (%)	94 (53)	91 (51)
Total duration of parenteral nutrition — days		
Median	13.5	13.0
Interquartile range	9.0–20.0	9.0–20.0
Antenatal corticosteroids — no. (%)	148 (83)	149 (83)
Score on the Edinburgh Postnatal Depression Scale†	10.7±5.7	10.0±5.3
Maternal educational level >high school — no. (%)	60 (34)	64 (36)
Maternal occupation score‡	4.5±1.4	4.6±1.3

* Plus–minus values are means ±SD.
† Scores range from 0 to 30, with higher scores indicating greater severity of depressive symptoms.[30]
‡ Data are the scores on Daniel's occupation scale[38]; scores range from 1 to 7, with lower scores indicating higher occupational prestige.

An independent safety monitoring committee, comprising a pediatric ophthalmologist, a neonatologist, and a pediatric respiratory physician–epidemiologist, all of whom were unaware of the treatment-group assignments, assessed adverse outcomes, including death, at five prespecified time points. The stopping rules were never breached.

RESULTS

PARTICIPANTS

Of the 703 infants who were eligible during the enrollment period, 158 met the criteria for exclusion before randomization. A total of 187 of the remaining 545 eligible infants were not enrolled (consent was not obtained for 122 infants, and the parent or guardian was not approached for 65 infants). There were 333 infants who underwent individual randomization, and an additional 25 eligible multiples were assigned to the same group as their sibling, for a total of 358 individual infants receiving one of the two treatments for whom outcomes were analyzed. A total of 178 infants were assigned to the standard-saturation group (target oxygen saturation, 91 to 94 percent) and 180 to the high-saturation group (target oxygen saturation, 95 to 98 percent). The two groups were well balanced in terms of the base-line characteristics of the infants and the mothers (Table 1). The intervention continued for a median of 17.5 days (interquartile range, 7.0 to 41.0) in the standard-saturation group and 40.0 days (interquartile range, 20.5 to 73.0) in the high-saturation group ($P<0.001$).

ADHERENCE TO THE PROTOCOL

Figure 1 shows the two distributions of the actual saturation levels. The median for each group was within the desired target range. Permitted protocol violations for open targeting of the oxygen saturation occurred relatively infrequently (on 54 occasions), generally for short periods (median, 7 days; interquartile range, 3 to 17), and the occurrences were equally distributed between the two groups.

PRIMARY OUTCOMES

The rate of ascertainment of primary outcomes was 93 percent in the standard-saturation group (165 of 178 infants) and 93 percent in the high-saturation group (168 of 180 infants). The median age at the assessment of the primary outcomes did not differ between the two groups (a corrected age of 12.1 months [interquartile range, 11.8 to 12.7] in the standard-saturation group and a corrected age of

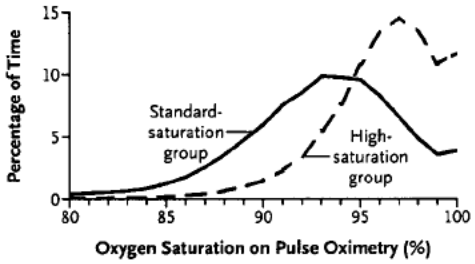

Figure 1. Smoothed Frequency Distribution of Actual Oxygen-Saturation Values on Pulse Oximetry during Oxygen Therapy after Randomization.

The saturation values were sampled every 10 seconds during intermittent downloads performed approximately twice weekly and lasting 8 to 24 hours each. The median oxygen saturation was 93 percent in the standard-saturation group (interquartile range, 90 to 96) and 97 percent in the high-saturation group (interquartile range, 94 to 98).

12.2 months [interquartile range, 11.9 to 12.9] in the high-saturation group).

There were no significant differences between the two groups in the mean weight, length, or head circumference at 38 weeks of postmenstrual age (Table 2). In addition, at a corrected age of 12 months, there were no significant differences in the measurements of weight, length, or head circumference; the proportion of infants who were small for their age; or the proportion of infants with a major developmental abnormality (Table 2). Our data also showed no significant difference between the two groups in the frequency of developmental scores that were more than 1 SD but less than 2 SD below the mean (relative risk associated with the higher oxygen-saturation target, 1.08; 95 percent confidence interval, 0.69 to 1.69; P=0.70). When the primary outcomes were examined in the subgroup of 256 infants born before 28 weeks of gestation, the differences between the two treatment groups remained nonsignificant and were similar

Table 2. Measures of Growth and Development.*

Outcome	Standard-Saturation Group	High-Saturation Group	Mean Difference (95% CI)	Relative Risk or Odds Ratio (95% CI)†	P Value
38 Wk of postmenstrual age

* Plus–minus values are means ±SD. Denominators are the numbers of infants for whom growth measures or major developmental abnormalities could be assessed at 12 months of corrected age. CI denotes confidence interval.

† The value for a head circumference below the 3rd percentile is an odds ratio; other values are relative risks.

‡ Major developmental abnormalities were blindness, cerebral palsy, or a general quotient on the revised Griffiths Mental Developmental Scales that was more than 2 SD below the mean.

in magnitude to those in the whole cohort (data not shown).

SECONDARY OUTCOMES

The proportion of infants who were still dependent on supplemental oxygen at 36 weeks of postmenstrual age was 46 percent in the standard-saturation group and 64 percent in the high-saturation group (P<0.001) (Table 3). Similarly, the proportion of infants requiring home-based oxygen therapy was significantly lower in the standard-saturation group than in the high-saturation group (17 percent vs. 30 percent, P=0.004) (Table 3). The duration of oxygen supplementation was significantly higher in the high-saturation group: the postmenstrual age at the cessation of oxygen therapy was 35.4 weeks in the standard-saturation group and 37.9 weeks in the high-saturation group (P<0.001) (Table 3). There were no significant differences between the two groups in the median total duration of assisted ven-

Table 3. Rates of Adverse Outcomes among the Infants.*

Outcome	Standard-Saturation Group (N=178)	High-Saturation Group (N=180)	Relative Risk or Odds Ratio (95% CI)†	Median Difference (95% CI)	P Value

‡ Data are for infants who underwent cryotherapy or laser therapy for threshold retinopathy of prematurity, usually stage 3 with dilatation of the posterior retinal vessels (referred to as "plus" disease).

tilation after randomization, the rate of use of postnatal corticosteroids or diuretics, the length of the hospital stay after randomization, the postmenstrual age at discharge, or the time before the infant was able to be fed entirely orally (Table 3).

There were no significant differences between the groups in the rates of retinopathy of prematurity of any stage or in the frequency of the need for ablative retinal surgery (in 20 of 178 infants in the standard-saturation group [11 percent] and 11 of 180 infants in the high-saturation group [6 percent], P=0.09) (Table 3). All the infants who underwent ablative retinal surgery were born before 28 weeks of gestation, and all but one of these infants retained vision in at least one eye. The rate of ablative retinal surgery among infants born before 28 weeks of gestation was 16 percent (20 of 124 infants) in the standard-saturation group and 8 percent (11 of 132 infants) in the high-saturation group (relative risk, 0.52; 95 percent confidence interval, 0.26 to 1.03; P=0.06).

There was no significant difference between the two groups in the number of infants who died: five infants in the standard-saturation group and nine in the high-saturation group (Table 3). Of these deaths, one in the standard-saturation group was due to pulmonary causes, as compared with six in the high-saturation group (P=0.12). The number of infants who were rehospitalized and the number of health service visits per infant during the first year of life did not differ significantly according to the treatment group (Table 4). There were also no significant differences between the two groups in the measures of maternal postnatal depression, infant or toddler temperament, parental stress, or effects on the family (Table 4). Follow-up rates for these tests ranged from 71 to 77 percent.

DISCUSSION

Our double-blind, randomized trial showed no evidence that the targeting of a functional oxygen-saturation range of 95 to 98 percent rather than a range of 91 to 94 percent had a beneficial effect on growth or development in preterm infants with a long-term dependence on supplemental oxygen. The targeting of higher oxygen-saturation levels resulted in a 40 percent increase in the proportion of infants who were still receiving oxygen therapy at 36 weeks of postmenstrual age and a 78 percent increase in the

Table 4. Use of Health Services in the First Year of Life and Psychosocial Measures in Parents and Infants.*

Outcome	Standard-Saturation Group	High-Saturation Group	Relative Risk (95% CI)	Difference between Groups (95% CI)†	P Value
Infant rehospitalized — no./total no. (%)	82/171 (48)	92/170 (54)	1.13 (0.92 to 1.39)		0.34
No. of health service visits/infant				3.8 (−0.8 to 8.5)	0.11
Median	27.5	31.3			
Interquartile range	25.1 to 30.4	27.3 to 34.8			
Scores on psychosocial measures‡					
Edinburgh Postnatal Depression Scale (mother)	5.9±5.1	6.5±4.8		0.6 (−0.6 to 1.8)	0.32
Infant Temperament Scale	2.3±0.7	2.4±0.7		0.1 (0.0 to 0.3)	0.06
Toddler Temperament Scale	3.2±0.6	3.1±0.6		−0.1 (−0.2 to 0.1)	0.59
Parenting Stress Index, Short Form	71.7±20.6	72.9±21.1		1.2 (−3.9 to 6.3)	0.65
Impact-on-Family Scale	40.0±11.0	39.8±11.7		−0.2 (−3.0 to 2.6)	0.89

* Plus–minus values are means ±SD. Scores on the Edinburgh Postnatal Depression Scale[30] range from 0 to 30, with higher scores indicating a greater severity of depressive symptoms. Scores on the Infant Temperament Scale[31] range from 1 to 6, with a mean (±SD) of 2.5±0.64; higher scores indicate a more difficult temperament. Scores on the Toddler Temperament Scale[32] range from 1 to 6, with a mean of 3.46±0.62; higher scores indicate a more difficult temperament. Scores on the Parenting Stress Index, Short Form,[33] range from 32 to 160, with a median of 69 (interquartile range, 61 to 79); higher scores indicate greater parental stress. Scores on the Impact-on-Family Scale[34] range from 19 to 76, with a mean of 46.2±7.6; higher scores indicate increased effects on the family. CI denotes confidence interval.

† The mean difference is shown for scores on psychosocial measures; the median difference is shown for health service visits.

‡ The score on the Infant Temperament Scale was obtained at 4 months of corrected age; scores on the other measures were obtained at 12 months of corrected age.

proportion receiving supplemental oxygen after discharge. Hence, one could expect one additional case of home-based oxygen therapy for every eight infants treated if higher target ranges for the oxygen saturation were used routinely.

The finding that oxygen therapy was required for a longer period in the high-saturation group might simply be explained by the fact that a higher target saturation had to be reached for oxygen therapy to be discontinued. However, a higher target oxygen saturation may also be associated with potential pulmonary toxicity. The unexpected finding of excess deaths from pulmonary causes among infants in the high-saturation group — albeit not statistically significant — accords with the findings of the only other trial in which preterm infants were randomly assigned to different target oxygen-saturation ranges, the Supplemental Therapeutic Oxygen for Prethreshold Retinopathy of Prematurity (STOP-ROP) trial.[39] That trial showed an increased rate of adverse pulmonary sequelae (although not an increased rate of death due to pulmonary causes) among preterm infants with prethreshold retinopathy of prematurity when a higher oxygen-saturation range was targeted.

Oxygen toxicity, particularly in preterm infants, can inhibit lung healing and contribute to ongoing lung injury.[40] In our trial, infants who were still dependent on supplemental oxygen at 36 weeks of postmenstrual age or before discharge did not routinely have oxygen-saturation data collected after a room-air breathing test, and we do not have information on the proportion of infants in the high-saturation group who would not have required oxygen had their oxygen-saturation target been lower. Thus, the cause of the greater oxygen requirement in the high-saturation group remains uncertain.

Although our trial did not have the statistical power to detect differences in secondary eye-related outcomes, the effect of different target oxygen-saturation ranges on retinopathy of prematurity is of interest, since infants were randomly assigned to the different treatments at 32 weeks of postmenstrual age, before threshold retinopathy of prematurity usually develops. The results of both the STOP-ROP trial and our trial suggest the possibility that the need for ophthalmic intervention may be reduced when a higher oxygen-saturation range is targeted in a subgroup of extremely preterm infants with more severe eye disease. However, the differences between the treatment groups were not significant at the $P<0.05$ level in our subgroup analysis, and this hypothesis requires confirmation in larger studies.

Our trial addressed only the question of the effects of two different target oxygen-saturation ranges in preterm infants who remained dependent on supplemental oxygen after 32 weeks of postmenstrual age. Hence, these results should not be extrapolated to practice recommendations for preterm infants at earlier postmenstrual ages. The question of the most appropriate oxygen-saturation range for preterm infants treated sooner after birth can be answered only in the context of further large, well-designed, randomized trials with good long-term follow-up.[21]

A possible limitation of the study is that the duration of follow-up may not have been sufficiently long to allow us to detect other clinically important outcomes, such as minor disabilities that may become manifest later in childhood. We found no significant difference in the rates of developmental scores that were more than 1 SD but less than 2 SD below the mean — an outcome that may be a surrogate for later minor disability.[41]

The results of this randomized trial contradict observational reports suggesting that there are benefits of the routine targeting of higher oxygen-saturation levels in preterm infants with a long-term dependence on supplemental oxygen.[13-16] We found no evidence of beneficial effects of higher oxygen-saturation levels on growth or neurodevelopmental outcomes in these infants, but we did find an increased burden on health services.

Supplemental Therapeutic Oxygen for Prethreshold Retinopathy of Prematurity (STOP-ROP), A Randomized, Controlled Trial. I: Primary Outcomes

The STOP-ROP Multicenter Study Group*

ABSTRACT. *Objective.* To determine the efficacy and safety of supplemental therapeutic oxygen for infants with prethreshold retinopathy of prematurity (ROP) to reduce the probability of progression to threshold ROP and the need for peripheral retinal ablation.

Methods. Premature infants with confirmed prethreshold ROP in at least 1 eye and median pulse oximetry <94% saturation were randomized to a conventional oxygen arm with pulse oximetry targeted at 89% to 94% saturation or a supplemental arm with pulse oximetry targeted at 96% to 99% saturation, for at least 2 weeks, and until both eyes were at study endpoints. Certified examiners masked to treatment assignment conducted weekly eye examinations until each study eye reached ophthalmic endpoint. An adverse ophthalmic endpoint for an infant was defined as reaching threshold criteria for laser or cryotherapy in at least 1 study eye. A favorable ophthalmic endpoint was regression of the ROP into zone III for at least 2 consecutive weekly examinations or full retinal vascularization. At 3 months after the due date of the infant, ophthalmic findings, pulmonary status, growth, and interim illnesses were again recorded.

Results. Six hundred forty-nine infants (325 conventional and 324 supplemental) were enrolled from 30 centers over 5 years. Five hundred ninety-seven (92.0%) infants attained known ophthalmic endpoints, and 600 (92%) completed the ophthalmic 3-month assessment. The rate of progression to threshold in at least 1 eye was 48% in the conventional arm and 41% in the supplemental arm. After adjustment for baseline ROP severity stratum, plus disease, race, and gestational age, the odds ratio (supplemental vs conventional) for progression was .72 (95% confidence interval: .52, 1.01). Final structural status of all study eyes at 3 months of corrected age showed similar rates of severe sequelae in both treatment arms: retinal detachments or folds (4.4% conventional vs 4.1% supplemental), and macular ectopia (3.9% conventional vs 3.9% supplemental). Within the prespecified ROP severity strata, ROP progression rates were lower with supplemental oxygen than with conventional oxygen, but the differences were not statistically significant. A post hoc subgroup analysis of plus disease (dilated and tortuous vessels in at least 2 quadrants of the posterior pole) suggested that infants without plus disease may be more responsive to supplemental therapy (46% progression in the conventional arm vs 32% in the supplemental arm) than infants with plus disease (52% progression in conventional vs 57% in supplemental).

Pneumonia and/or exacerbations of chronic lung disease occurred in more infants in the supplemental arm (8.5% conventional vs 13.2% supplemental). Also, at 50 weeks of postmenstrual age, fewer conventional than supplemental infants remained hospitalized (6.8% vs 12.7%), on oxygen (37.0% vs 46.8%), and on diuretics (24.4% vs 35.8%). Growth and developmental milestones did not differ between the 2 arms.

Conclusions. Use of supplemental oxygen at pulse oximetry saturations of 96% to 99% did not cause additional progression of prethreshold ROP but also did not significantly reduce the number of infants requiring peripheral ablative surgery. A subgroup analysis suggested a benefit of supplemental oxygen among infants who have prethreshold ROP without plus disease, but this finding requires additional study. Supplemental oxygen increased the risk of adverse pulmonary events including pneumonia and/or exacerbations of chronic lung disease and the need for oxygen, diuretics, and hospitalization at 3 months of corrected age. Although the relative risk/benefit of supplemental oxygen for each infant must be individually considered, clinicians need no longer be concerned that supplemental oxygen, as used in this study, will exacerbate active prethreshold ROP. *Pediatrics* 2000;105:295–310; *retinopathy of prematurity, oxygen therapy, visual loss, oxygen toxicity, prematurity, neonatal outcomes, bronchopulmonary dysplasia.*

ABBREVIATIONS. ROP, retinopathy of prematurity; CRYO-ROP,

cryotherapy for ROP; STOP-ROP, Supplemental Therapeutic Oxygen for Prethreshold ROP; PMA, postmenstrual age; SES, socioeconomic status; CLD, chronic lung disease; CPAP, continuous positive airway pressure; OR, odds ratio; CI, confidence interval.

Retinopathy of prematurity (ROP) is a neovascular retinal disorder that develops in 84% of premature survivors born at <28 weeks' gestation. Fortunately, ROP resolves in most cases (80%) without visual loss from retinal detachments or scars.[1,2] The multicenter study of cryotherapy for ROP (CRYO-ROP) study showed that, when the disorder progresses, ablation of the avascular peripheral retina with cryotherapy reduced the incidence of retinal detachment from 51% to 31%.[3] Peripheral retinal ablation, now usually by laser therapy, has become standard treatment for advanced ROP.[4–7] However, this therapy is not always successful in halting the progression of ROP, and the long-term complications of extensive ablation of the developing peripheral retina beyond 5 years of age[7] are as yet unknown.

In 1948, Michaelson[8] proposed that a gradually increasing oxygen deficit of the oxygen-consuming retina during normal differentiation causes release of an angiogenic growth factor. Based on this supposition, therapeutic administration of supplemental oxygen to relieve the putative hypoxic stimulus for retinal neovascularization has been considered. In the 1950s, Szewczyk[9] and Bedrossian et al[10,11] first reported the use of supplemental oxygen to treat the neovascularization in ROP. This approach was abandoned after the 1956 Cooperative Study of Retrolental Fibroplasia demonstrated that prolonged (4 weeks) administration of 50% oxygen caused increased rates of ROP and vision loss.[12] But the concept of an hypoxic stimulus for retinal neovascularization remained biologically plausible and eventually regained scientific interest and attention.

Case–control studies revealed that infants who develop severe ROP, compared with infants of similar gestation and birth weight who do not have ROP, have hospital courses characterized by more complex medical problems, prolonged oxygen requirements, lower overall arterial oxygenation levels, and more episodes of fluctuating blood oxygen levels.[13–15] In contrast to healthy neonates breathing room air, whose arterial oxygen levels are similar to those of adults (95–100 mm Hg [13 pKa]), the recommended arterial concentrations for premature infants receiving oxygen are 50 to 80 mm Hg (6.6–10.6 kPa).[16] This relative hypoxia in premature infants raised the possibility that supplemental oxygen might be used to improve retinal oxygenation and down-regulate retinal neovascularization. Tests of the effects of such oxygen supplementation in animal models of ROP supported this hypothesis,[17,18] and a reported benefit of supplemental oxygen in a clinical case series[19] provided additional support for systematically testing the hypothesis in premature infants with ROP. We report the primary results from the Supplemental Therapeutic Oxygen for Prethreshold ROP (STOP-ROP) study, which was designed to test the hypothesis that supplemental oxygen, given to attain a pulse oximetry range of 96% to 99% saturation, would reduce by one third the proportion of infants with at least 1 eye progressing from moderate ROP (prethreshold) to threshold ROP requiring peripheral ablative surgery, without unacceptable side effects.[20]

METHODS

Study Design

The study design was a randomized trial comparing the effects of 2 oxygenation strategies on the progression of ROP: conventional oxygenation at a pulse oximetry target of 89% to 94% versus supplemental oxygen to achieve a pulse oximetry target range of 96% to 99%.[21] From February 1994 to March 1999, eligible patients from 30 centers were typically enrolled by telephone call to the central coordinating center (64%) after confirmation of eligibility and signed informed consent by parents or legal guardians. Random assignments were generated by the coordinating center using the Wei-Lachin Urn Scheme[22] and were stratified by center and by 2 levels of baseline ROP severity. When the coordinating center was not available, study centers used sequentially numbered, sealed envelopes provided in advance by the coordinating center to obtain treatment assignments, and submitted appropriate documentation to the coordinating center. An infant was assigned to the severe ROP stratum A whenever either study eye had 1 or more clock hours of any stage ROP in zone I, or when the fellow eye was already at threshold or worse ROP (see Table 1), thereby eliminating that eye as a study eye. The remaining infants fell in the less severe ROP stratum B with zone II prethreshold ROP in both eyes or in the second eye at less than prethreshold ROP. Family, bedside nurses, and attending neonatologists knew the treatment assignment, but the study-certified ophthalmologists who assessed eligibility, progression of the ROP, and study end-

TABLE 1. Definitions of ROP Severity Categories for STOP-ROP

Threshold ROP*	
Zone II	Presence of posterior pole dilation/tortuosity in at least 2 posterior pole quadrants (plus disease), and stage 3 ROP for at least 5 contiguous clock h or 8 composite clock h
Zone I	ROP (any stage) with posterior pole dilation/tortuosity in at least 2 posterior pole quadrants (plus disease), or stage 3 ROP, with or without plus disease
Beyond threshold	Stage 4 ROP, stage 5 ROP, or massive vitreal hemorrhage obscuring the view of the fundus
Prethreshold ROP	
Zone II	Any number of clock hours of stage 3 ROP, less than threshold severity, or any stage 2 ROP with at least 2 quadrants of posterior pole dilation/tortuosity disease (plus disease)
Zone I	Any ROP less than threshold severity

Stages and zones based on the international classification of ROP.[24]

* The definition of threshold ROP differs somewhat from that used in the CRYO-ROP study[4] in 2 ways: 1) In the CRYO-ROP study, "plus disease" was a global assessment of the posterior pole and was not determined according to number of quadrants involved, and 2) in the CRYO-ROP study, the definition of threshold was the same for both zone I and zone II and is the same as stated for zone II above (except for the number of quadrants of posterior pole dilation/tortuosity, as described in note 1). In STOP-ROP, a less stringent definition of threshold in zone I was used to accommodate the clinical judgment of a majority of the participating ophthalmologists that earlier treatment was needed to improve the poor outcomes of zone I threshold ROP.

points remained masked to treatment assignment throughout the study.

The primary endpoint of this study of systemic oxygen therapy was based on the infant, ie, progression of at least 1 study eye of an infant to threshold ROP (Table 1). Infants had only 1 study eye if the fellow eye was already at threshold or worse than threshold ROP at enrollment. Otherwise, they had 2 study eyes; even a fellow eye at less than prethreshold severity was considered a study eye, because it was going to be exposed to the assigned treatment and could progress to threshold ROP. Secondary endpoints included ophthalmic status at 3 months after due date, infant growth rates, developmental screening, and adverse medical events. The protocol was reviewed and approved by the institutional review board at each participating site before initiation of recruitment at that site.

Eligibility Criteria

Premature infants were screened for ROP, according to local guidelines consistent with the 1992 recommendations of the American Academy of Pediatrics,[16] at 71 hospitals affiliated with 30 certified participating centers throughout the United States. Infants with prethreshold ROP in at least 1 eye (Table 1) were registered as potentially eligible for the study and monitored for a minimum of 4 hours with continuous pulse oximetry. Registered candidates were excluded as ineligible whenever their median pulse oximetry was greater than 94% saturation while breathing room air or they had lethal anomalies or congenital anomalies of the eye. The family or guardian of eligible infants was approached for consent if the attending neonatologist agreed that randomization to either oxygen saturation target range could be achieved and would be medically safe, and that the infant's caretaker would be able to comply with the follow-up appointments. The diagnosis of prethreshold ROP in at least 1 eye then had to be confirmed independently by a second examiner to qualify for randomization. At least 1 of the 2 examiners had to be certified by the STOP-ROP study; usually both were.

Intervention

Although randomization and initiation of treatment within 24 hours of the diagnosis of prethreshold ROP was the goal, later enrollment was permitted as long as at least 1 eye was verified as remaining at prethreshold within the preceding 48 hours. The treatment assignment was for the infant to be placed on continuous pulse oximetry monitoring and to maintain oxygen saturation, as much as possible, in the target range of either 89% to 94% (conventional) or 96% to 99% (supplemental). Ohmeda 3740 pulse oximeters and laptop computers with software to monitor, record, and report trends in oxygen saturation were provided by the study for each infant. The Ohmeda 3740 pulse oximeter is calibrated at the factory to display a saturation lower by 1.6 saturation points, compared with other commercial oximeters, to correct for assumed carboxyhemaglobin and methemaglobin levels. Oximeters provided continuous data to a laptop computer that displayed real-time oxygen saturation summary graphs and tables updated every 20 seconds. The percent time in the assigned target range over varying time periods was displayed (Fig 1). Whenever the oxygen saturation was out of the target range for >10 of the previous 20 minutes and the saturation was currently out of range, the computer produced a unique alarm. The alarm limits on the oximeter itself were set according to the each hospital's usual policy. Using this continuous feedback, the bedside nurse or family could readily make necessary adjustments to the oxygen environment to maximize the time spent in the assigned target range. Pulse oximetry values were recorded to a computer disk every 40 seconds during the weeks the infant was on study equipment.

Study saturation targets continued for a minimum of 2 weeks, even if ophthalmic endpoints were reached in both eyes sooner. After those 2 weeks, treatment assignment and equipment were stopped after both eyes reached ophthalmic endpoints. Brief periods off equipment were allowed for procedures or baths. Occasionally an infant was ready for discharge home before reaching study endpoint in both eyes. The parents or guardians were then trained to use the study oximeter and computer to permit the assigned treatment to be continued, recorded, and completed at home.

Outcome Variables

Study-certified ophthalmologists and study center coordinators examined enrolled infants weekly until both eyes reached oph-

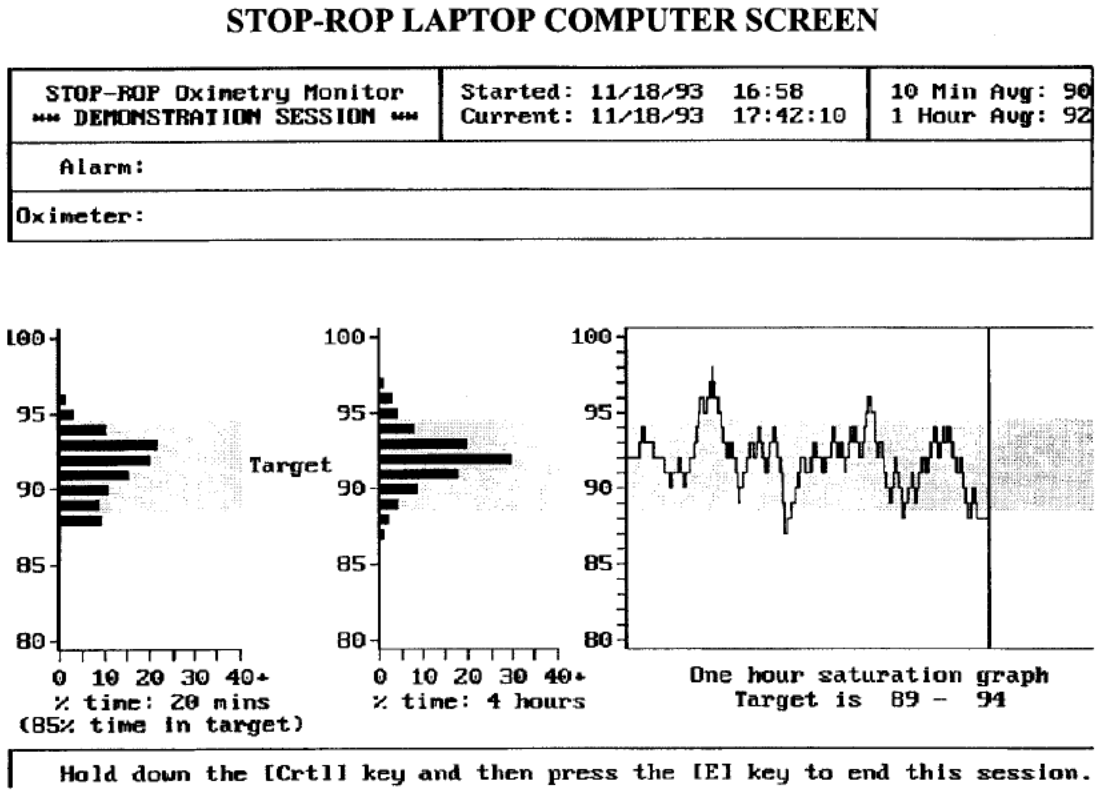

Fig 1. Computer screen format. Frequency distributions and oximetry strip chart information provided continuously at the bedside for nursing management of the pulse oximetry study targets. In this sample, the infant is assigned to the conventional arm (89%–94% saturation), the area highlighted in gray.

thalmic endpoints and again at 3 months' corrected age (that is, 3 months past the term due date of 40 weeks' postmenstrual age [PMA]). The computers and oximeters were covered during examinations to maintain masking of the ophthalmologists. To standardize diagnoses, all ophthalmologists were certified in the completion of study data forms. If they had not been previously certified during the acute phase of the CRYO-ROP or Light Reduction-ROP studies,[23] their use of the international classification of ROP[24] was certified by study headquarters through a series of dual examinations of infants with ROP. Standard fundus photographs of degrees of severity of posterior pole dilation/tortuosity were provided to each center for use at the bedside to promote uniformity of the diagnosis (Fig 2). For the STOP-ROP study, plus disease was defined as "at least 2 quadrants of dilation and tortuosity of the posterior pole vessels." Study personnel completed annual recertification throughout the study.

An adverse ophthalmic endpoint was defined as progression to threshold ROP (or worse), diagnosed by 1 study-certified ophthalmologist and confirmed independently by a second study-certified ophthalmologist. Eyes confirmed to have reached threshold ROP were referred for possible cryotherapy or laser therapy. The definition of threshold ROP (Table 1) in zone II was the same as that used by the CRYO-ROP study; however, in zone I, the definition was modified to permit a diagnosis of threshold at slightly less severity of ROP than required by the CRYO-ROP study because zone I threshold ROP, as defined in CRYO-ROP, progressed to poor retinal outcomes in 78% of eyes even with cryotherapy.[3]

A favorable ophthalmic endpoint was defined as regressing ROP in zone III for at least 2 successive weekly examinations, or full retinal vascularization. Ophthalmic outcomes at 3 months' corrected age were classified as: 1) unfavorable when there were findings of total or partial retinal detachment or when the visual axis was otherwise obstructed, 2) indeterminate when there was macular ectopia, or 3) favorable when there were only minor peripheral findings, laser or cryotherapy scars, or active ROP in zone II or III. The uncommon finding of continued active ROP at 3 months' corrected age was followed whenever possible with a repeat examination at 6 months' corrected age, although this situation had not been anticipated when the STOP-ROP protocol was developed. Whenever missed examinations or death caused incomplete endpoint dating or diagnosis of an eye's endpoint, all available eye data were provided to an ophthalmic endpoints committee of 3 ophthalmologists masked to the treatment assignment. The committee reached consensus on the outcome of each eye according to the following categories: 1) almost certainly reached adverse ophthalmic endpoint, 2) may have reached adverse ophthalmic endpoint, 3) indeterminate, 4) may have reached favorable ophthalmic endpoint, or 5) almost certainly reached favorable ophthalmic endpoint. Only consensus votes of 1 or 5 were used in any subsequent secondary analyses, and the committee was unaware of this analysis decision when they met (votes 2, 3, or 4 were treated as unknown).

Pediatric data were recorded at the time of randomization, at weekly intervals throughout the intervention period, and again at 3 months' corrected age. These data included duration of oxygen use and hospitalization after randomization; weight, length, and head circumference; use of diuretics, methylxanthines, or steroids; a checklist of specified adverse events; and episodes of rehospitalization. The age for achieving full nipple feeds was determined as the first day of 3 consecutive days of taking all enteral feedings by mouth. The questions for the Hollingshead classification of socioeconomic status (SES) were asked at discharge.[25] Adverse events, rehospitalizations, and deaths before 3 months' corrected age were reported as they occurred. The Revised Parental Denver Questionnaire was administered at 3 months' corrected age.[26]

All deaths and rehospitalizations were reviewed by 3 neonatologists masked to treatment assignment to determine whether pulmonary disease was the primary cause of death or rehospital-

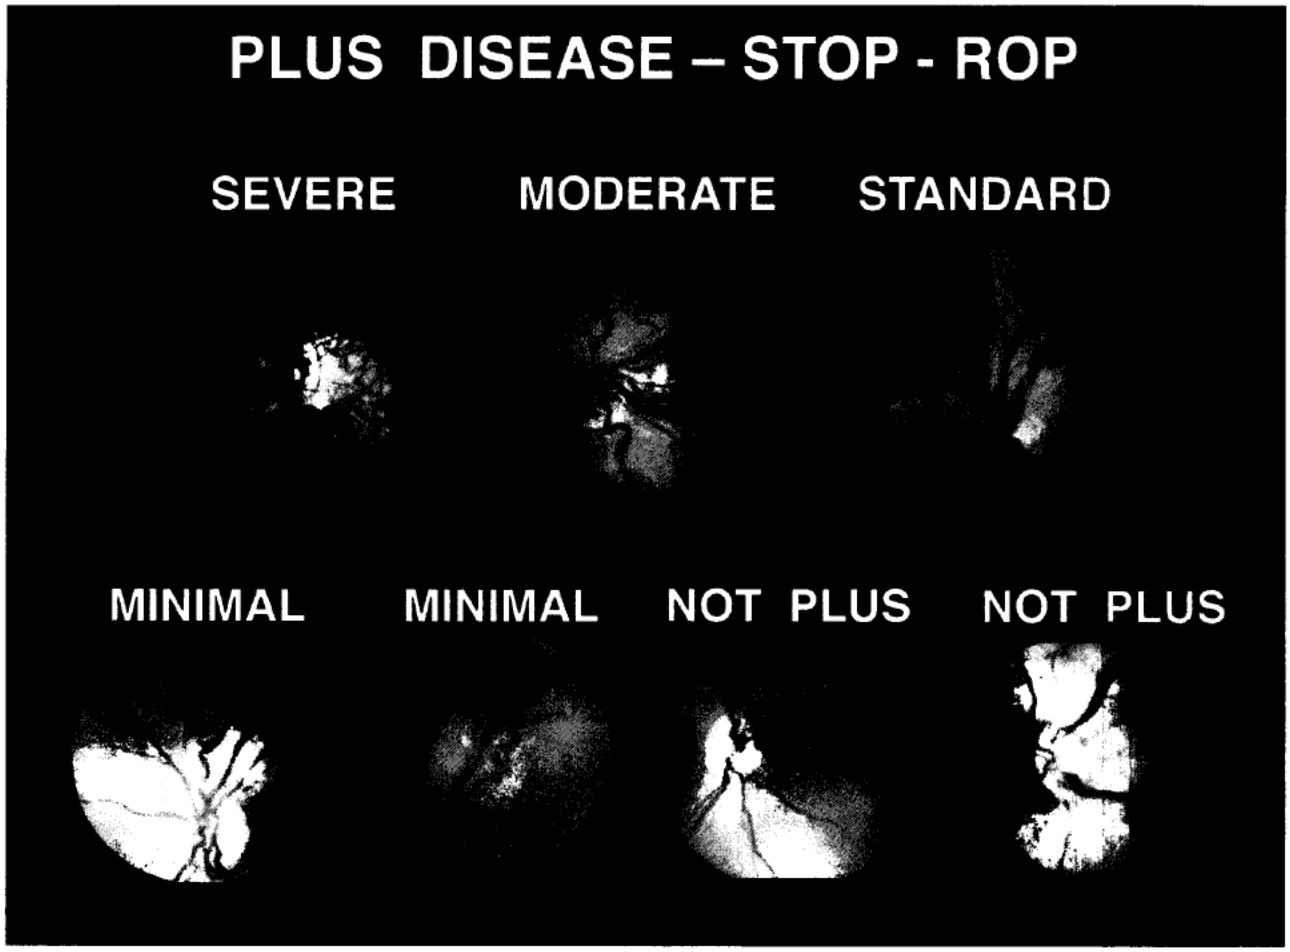

Fig 2. Standard photographs for the STOP-ROP study: fundus photographs of the posterior pole (visible with a direct ophthalmoscope), showing examples of mild to moderate posterior pole dilation/tortuosity and samples of retinas without this finding.

ization. Pneumonia/chronic lung disease (CLD) events were defined as probable or definite pneumonia, an acute exacerbation of CLD, or some combination of these 2 such that the study neonatologist could not distinguish between them.

Pulmonary Score

A composite pulmonary score was developed to describe the pulmonary status of each infant at baseline. The pulmonary score was calculated as:

$$\text{Pulmonary score} = (F_{IO_2})\ (\text{support}) + (\text{medications})$$

where F_{IO_2} is expressed as a fraction (room air = .21); support = 2.5 if on ventilator, 1.5 if on nasal or endotracheal continuous positive airway pressure (CPAP), and 1.0 if on nasal cannula, hood oxygen or off oxygen; and medications = .05 each for methylxanthines or intermittent diuretics, .10 for daily diuretics, .10 for inhaled steroids, and .20 for systemic steroids for CLD. Therefore, the pulmonary score could have a range of values between .21 (no pulmonary support, oxygen, or medications) and 2.85 (assuming that an infant would not be on both inhaled and systemic steroids). The baseline pulmonary score correlated well with pulmonary rehospitalizations, pulmonary deaths, and markers of CLD severity, such as duration of oxygen therapy (data not shown).

Sample Size and Data Monitoring

The progression rate to threshold was monitored by the Data and Safety Monitoring Committee at annual meetings. An early stopping guideline was constructed for ophthalmic benefit at an overall α-value of .025, and a stopping guideline for ophthalmic harm at an overall α-value of .10, allowing for repeated interim analyses[27] using the software of Reboussin (Madison, WI, University of Wisconsin, Department of Statistics). A sample size of 880 infants (to achieve 816 cases with final outcome data) was calculated as necessary to provide 90% power with an overall type I error rate of .025 to detect a one third reduction in progression to threshold disease or a 10% absolute reduction based on a predicted rate of progression of 30% in the conventional arm.[1] Adverse events were reviewed biweekly, and deaths were reviewed immediately by a neonatologist on the Data and Safety Monitoring Committee. All adverse events were reviewed at each meeting of the full Committee.

In 1997, the Data and Safety Monitoring Committee, after the enrollment of 449 children over 3.3 years, expressed concern about the ability of the study group to enroll the target number of 880 infants within 5 years, given consistent enrollment rates averaging 11.2 infants per month. Furthermore, new reports of nonrandomized case series in human infants suggesting a strong beneficial effect of supplemental oxygen,[28,29] as well as publication of additional animal model data,[30–35] supported the hypothesis of the STOP-ROP study, which might adversely affect enrollment. Calculations at that time showed that an enrollment of 633 infants completing the study would provide 83% power to detect a fall in the progression rate from 30% to 20%. The Committee members, who were not masked to study ophthalmic outcomes (although masked to treatment assignment) at the time of the review, recommended that recruitment continue through March 1999 with a revised enrollment goal of at least 633 infants. The final number of 649 enrollees, with ophthalmic endpoints available for 597, resulted in a power of ~80% against the designed alternative.

Statistical Analyses

Primary analyses were performed on all enrollees according to the assigned treatment arm (intention-to-treat) using the group-sequential method of Kim and DeMets.[27] Secondary categorical characteristics of the patients in the 2 arms were compared by χ^2 test, and group differences of continuous factors were compared with Student's t test and Wilcoxon rank-sum test. Logistic regression was used for the adjustment of progression rates for covariates. All P values presented are 2-sided and are unadjusted for the 5 interim examinations of the data, ie, are nominal P values, unless otherwise specified. Analyses were conducted with SAS software (SAS Institute, Cary, NC).[36]

RESULTS

Patients

Comparability of Enrolled and Registry Infants

From February 9, 1994, through March 31, 1999, 1847 infants with prethreshold ROP in at least 1 eye were registered at the participating centers. Of these, 634 (34%) were ineligible because either their pulse oximetry was greater than 94% in room air, or they had fatal or congenital eye anomalies (Fig 3). Of 1213 clinically eligible infants, 649 (54%) were enrolled. Reasons for nonenrollment were refusals of the family/guardians or the neonatologist (368), nonconfirmed prethreshold ROP (41), enrollment in conflicting studies (9), judgment that the infant was too ill to attempt randomization to the supplemental arm (28), inability of the family to comply with follow-up visits (41), imminent transfer to another hospital (8), and others. Of the ineligible infants, 99% had pulse oximetry greater than 94% in room air. Nonenrolled infants, including both those ineligible and those eligible but not enrolled (1198), weighed more at birth than enrolled infants (787 ± 287 vs 726 ± 160 g; $P < .001$) and had a slightly higher gestation at birth (25.7 ± 1.8 vs 25.4 ± 1.5 weeks; $P < .01$).

Comparability of Treatment Arms

Of the enrolled infants, 325 were randomized to the conventional arm, 324 to the supplemental arm, and their study completion rates are shown in Fig 3. The primary ophthalmic endpoint was available for 597 (92%) and was not recorded for 52 infants because of death (2), parental withdrawals from the study treatment (18), treatment with cryotherapy/laser before reaching ophthalmic endpoints (5), and missed eye examinations (27). Ophthalmic evaluations at 3 months' corrected age were completed for 600 infants and were unavailable for 49 because of death (16), withdrawal (31), and loss to follow-up (2). (Three additional infants in the supplemental arm not shown in the figure returned for just the neonatal portion of the 3-month evaluation). Rates of noncompletion were similar for both treatment arms (Fig 3).

Baseline demographic and pediatric characteristics are shown in Table 2, and ophthalmic baseline characteristics in Table 3. Randomization resulted in similar groups. Enrollment and randomization occurred at a PMA (PMA = gestational age at birth plus chronological age) of 35.4 ± 2.5 weeks (range: 30–48 weeks). The baseline pulmonary severity score and the mode of oxygen support were similar between the 2 arms. Many infants were on diuretics (54%) and methylxanthines (70%), and 29% had received steroids for CLD in the week before enrollment.

The ophthalmic baseline characteristics shown in Table 3 were also similar between the conventional and supplemental arms. There were no significant differences between the treatment arms in the number of infants enrolled in each ROP severity stratum or substratum. For the more severe forms of ROP represented in stratum A, 4.3% of enrollees had 1 eye at or beyond threshold (therefore, only 1 study eye), and 23.4% had 1 or both eyes with at least 1 clock hour of ROP in zone I. In stratum B, infants with

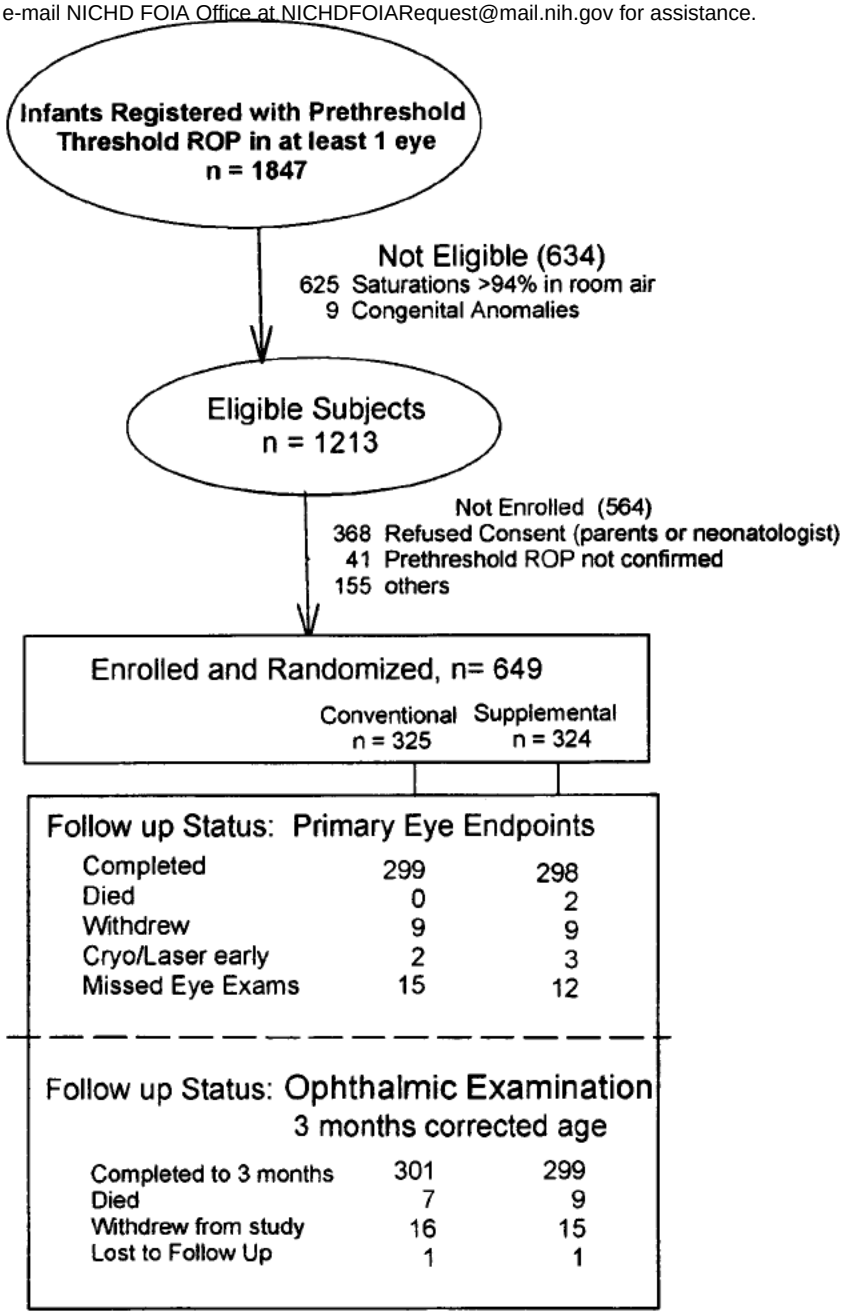

Fig 3. Patient enrollment flow diagram. There were several subjects without primary ophthalmic endpoints who nonetheless continued with follow-up examinations; therefore, there are more completed 3-month examinations than primary ophthalmic endpoints. Three additional supplemental infants completed the 3-month neonatal outcome examination, although they failed to complete the ophthalmic 3-month examination (not shown in figure).

zone II ROP in both eyes comprised 51% of all enrollees, and the remaining 21% entered the trial with the prethreshold eye's fellow eye at less than prethreshold ROP. There were no significant differences between the 2 arms in the number randomized within the first 24 hours after observing prethreshold ROP and in the numbers randomized after a longer period (Table 3). The elapsed time from the first diagnosis of prethreshold ROP to randomization was <24 hours in 33% of infants and >48 hours in 27% of infants.

Adherence to the Protocol

Oxygen requirements increased significantly for the infants randomized to the supplemental range. The average oxygen concentration increased from 36% ± 14% pretreatment to 46% ± 20%, 24 hours after randomization for those infants on a ventilator, CPAP, or hood oxygen; the average increase was 9.5% ± 16.5%. For infants on nasal cannula, the interactions between flow, infant size, and the oxygen concentration administered by cannula made estimation of the change in oxygen concentration more complex. Using the conversion formula of Benaron and Benitz,[37] average transformed oxygen concentration for infants on nasal cannula rose from 26% ± 6% before, to 31% ± 11% 24 hours after randomization to the supplemental arm; the average increase was 5% ± 9%. During the same 24-hour period, infants assigned to the conventional arm experienced a change from 36% ± 17% to 32% ± 15% in the infants on a ventilator, CPAP, or hood oxygen, and from 28% ± 10% to 26% ± 11% in the nasal cannula infants. (The 53 conventional and 25 supplemental

* Each study arm column gives the percentage of all subjects in that column whose median pulse oximetry over the first 2 weeks on study was at the level shown in the left hand column.

only 1.8% of median saturations of infants assigned to supplemental therapy were in the conventional range or lower. Pulse oximetry was recorded from all enrollees for these first 2 weeks of study participation, but beyond this period, as the eyes reached study endpoints, fewer infants remained on equipment to contribute to the accumulating oximetry data. In addition, as some infants in the conventional arm had resolution of their CLD, their saturations became greater than 95% while breathing room air. Figure 4 shows the smoothed overall frequency distribution of the saturation values (1 reading every 40 seconds) for the full period until ophthalmic endpoints for all infants enrolled. These data also include the 81 conventional and 85 supplemental infants who continued to use study equipment at home. Refusal of the parents or guardians to take the study equipment home on the day of discharge was a primary cause of premature cessation of pulse oximetry and study assigned oxygenation, occurring in 26 conventional and 24 supplemental subjects. Many of these families/guardians were willing to continue returning for weekly follow-up examinations, and therefore, were not withdrawn from the study. Comparison of the SES of families who refused equipment, with those that accepted it at home, showed no relationship between SES and refusal of this major home challenge, nor success in remaining in the target zones at home (data not shown).

Ophthalmic Outcome Data

The primary outcome, the proportion of infants with at least 1 eye progressing to confirmed threshold ROP, is shown by treatment arm in Table 5 for all infants and for subgroups of infants defined by baseline ophthalmic characteristics. Overall, 48.5% (145/299) of infants with study endpoints and assigned to the conventional arm progressed to confirmed threshold ROP in at least 1 eye, compared with 40.9%

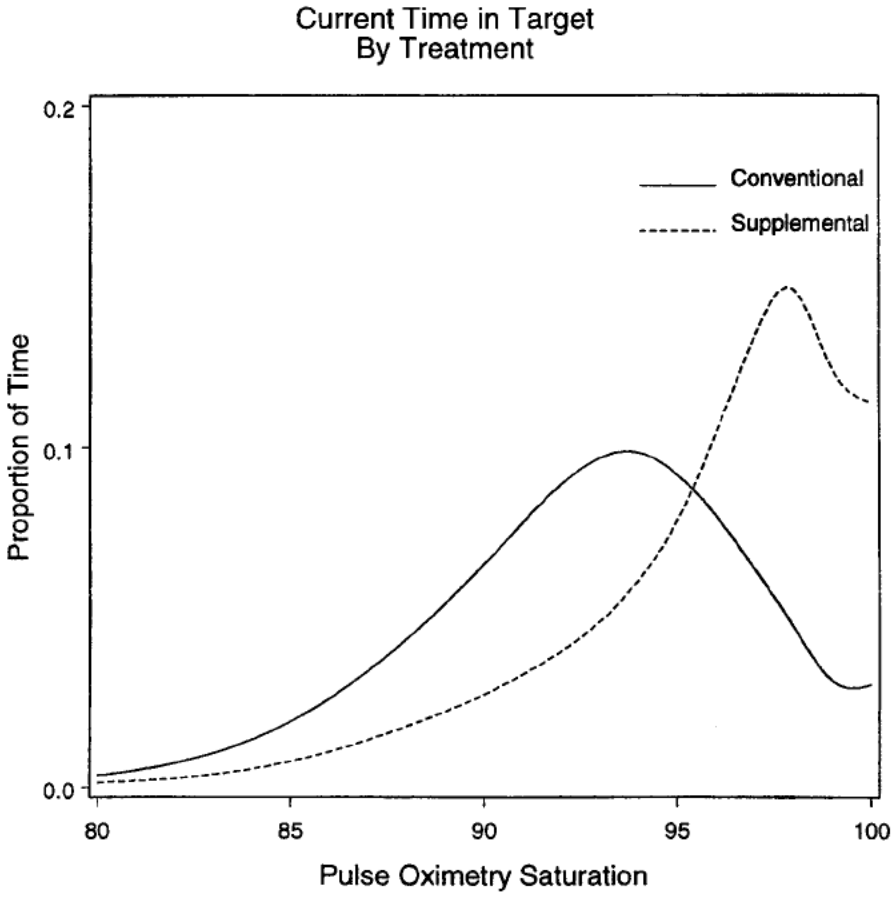

Fig 4. Smoothed frequency distribution of pulse oximetry saturation values for the conventional and supplemental oxygen arms throughout the duration of time on study equipment. Pulse oximetry saturation values were recorded to disk for later analysis once every 40 seconds throughout the time an infant remained on study equipment (range: 2–25 weeks).

* Infant ophthalmic outcomes based on progression of at least 1 study eye to threshold ROP. If an infant entered the study with 1 eye already at threshold or worse, that eye was not a study eye, and the infant's outcome is based on only the study eye.
† "Eye endpoints" means that for that infant, the primary endpoint of either 1) at least 1 eye progressing to threshold, or 2) all study eyes not progressing to threshold is known.
‡ PT indicates prethreshold ROP.
§ "Plus disease infants" are those who have at least 2 quadrants of posterior pole dilation/tortuosity in at least 1 study eye, whereas "non-plus disease infants" have all study eyes with 0 or 1 quadrant of posterior pole dilation/tortuosity.
‖ Mean ± standard deviation.

(122/298) in the supplemental arm. The difference between treatment arms was not significant at the designed 1-tailed α-level of .025, as adjusted for sequential testing. However, the difference was still suggestive, with a 1-tailed P value adjusted for repeated interim analyses of .032.[38] When eyes whose outcomes could be assigned by the Ophthalmic Endpoints Committee were included (31 infants: 15 conventional and 16 supplemental), the progression rates remained similar: 46.2% (145/314) and 39.5% (124/314) for the conventional and supplemental arms, respectively (data not shown).

Analysis by stratum or zone of baseline ROP yielded similar results. The high severity ROP stratum A infants progressed to threshold more frequently than the lower risk stratum B infants (50% vs 43% overall). Higher rates of progression in the conventional arm than in the supplemental arm were observed for both ROP severity strata (55%–46% in stratum A and from 46%–39% in stratum B). When severity was alternatively examined by zone of prethreshold ROP, progression rates also were lower in the supplemental arm (56% vs 49% for zone I and 46% vs 37% for zone II; conventional vs supplemental, respectively); however, none of these differences were statistically significant. In contrast, when progression rates were examined in relation to plus disease, the subgroup analysis revealed a difference. Infants without plus disease in either study eye progressed to threshold 46% versus 32% of the time in the conventional and supplemental arms, respectively (P = .004). When at least 2 quadrants of posterior pole dilation/tortuosity were present in either study eye at baseline, 52% of conventional versus 57% of supplemental infants had at least 1 eye progress to threshold (P = .484).

Adverse outcomes occurred soon after randomization in both groups as shown in Fig 5A, and the elapsed time from study entry to adverse ophthalmic endpoints was slightly longer in the supplemental arm compared with the conventional arm. Mean progression time to threshold disease was 2.4 weeks for eyes in the conventional arm and 2.7 weeks for eyes in the supplemental arm. Eyes with plus disease at study entry progressed to threshold disease most rapidly, at a mean of 1.6 and 2.2 weeks in the conventional arm and supplemental arm, respectively. Eyes without plus disease took somewhat longer (mean of 2.3 weeks and 2.7 weeks, respectively; Table 5). Achieving a favorable outcome took longer (Fig 5B), and the time to full vascularization or zone III vessels on 2 consecutive examinations in eyes

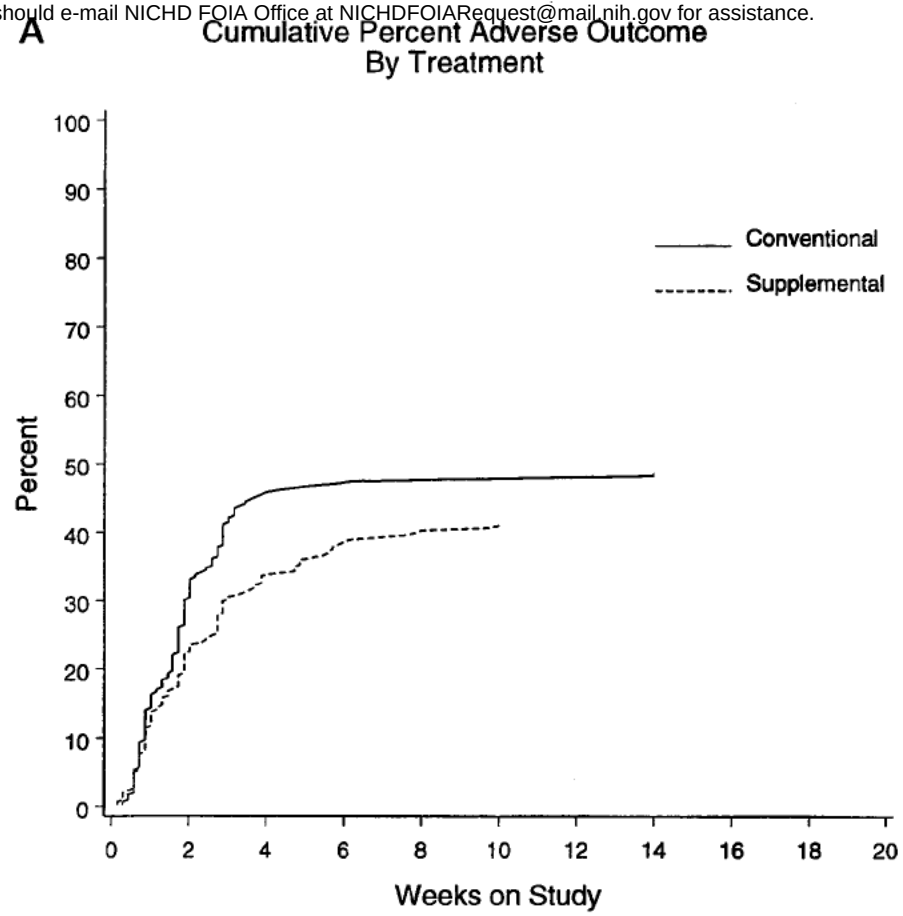

Fig 5. Cumulative rate curves demonstrating the differences in both the proportion and timing of adverse (A) and favorable (B) ophthalmic outcomes by study arm.

without progression to threshold disease occurred in the conventional arm at a mean of 9.0 weeks and in the supplemental arm at a mean of 9.5 weeks. Threshold ROP, when it occurred, was diagnosed at an average PMA of 36.8 weeks (range: 31.6–50.9 weeks) in the conventional arm, and an average of 37.3 weeks' PMA (range: 32.3–45.1 weeks) in the supplemental arm (data not shown in table).

Multiple regression analysis was conducted to adjust for minor variations in baseline characteristics with both simple and complex models. The complex model included treatment assignment, ROP stratum, race, gender, gestational age, small for gestational age status, the baseline pulmonary severity score, plus disease, late versus on-time enrollment, degree of compliance with assigned saturations, interactions of these variables with treatment assignment, and study center. The analysis did not alter the conclusions, but did confirm that both black race (odds ratio [OR]: .44; 95% confidence interval [CI]: .20,.94) and higher gestational age (OR: .80 per week; 95% CI: .66,.98) provide important significant protective effects in reducing the chance of progression of prethreshold ROP to threshold ROP, regardless of treatment arm, while having 2 or more quadrants of posterior pole dilation/tortuosity (plus disease) increased the risk of progression to threshold (OR: 1.71; 95% CI: .95,3.10). In the simplified model, the OR for the supplemental arm after adjustment for ROP risk stratum, plus disease, race, and gestational age was .72 (95% CI: .52,1.01).

Peripheral ablation utilized laser therapy in 93% of treated eyes (73% diode and 20% Argon) and cryotherapy alone in 7%. Four percent of treated eyes received both laser and cryotherapy. Final ophthalmic outcomes based on all study eyes at 3 months' corrected age (or 6 months for 12 conventional and 18 supplemental eyes) revealed adverse outcomes (partial or total retinal detachment, retinal folds, or obstruction of the visual axis) in 4.4% of the study eyes in the conventional and 4.1% in the supplemental arms, and macular ectopia in an additional 3.9% of the study eyes of the conventional arm and 3.9% of the study eyes of the supplemental arm. Among just those eyes that developed threshold ROP and were treated with peripheral surgical ablation, 9.2% in the conventional arm and 13.2% in the supplemental arm had adverse ophthalmic outcomes at 3 to 6 months (excludes macular ectopia that occurred in 6.3% of conventional and 7.7% of supplemental laser/cyro-treated eyes).

Pediatric Outcomes

We hypothesized that infants in the supplemental arm would grow and gain weight faster than infants in the conventional arm, but there were no differences between their growth rates during the initial first 2 weeks, later during the hospitalization period (data not shown), or at 3 months' corrected age (Table 6).

However, markers of CLD severity both during hospitalization and remaining at 3 months' corrected age (50 weeks' PMA) suggest a somewhat worse pulmonary status in the supplemental arm after randomization, although there were no differences in the baseline status measures (Table 2). As shown in Table 6, the conventional arm had fewer infants with 1 or more episodes of pneumonia or CLD exacerbation than did the supplemental arm, 25 (8.5%) versus 38 (13.2%; $P = .066$), and there were also fewer total episodes in the conventional arm (29 vs 51). Using the baseline pulmonary scores to further examine this, infants were divided into higher and lower pulmonary risks at the overall median pulmonary score of .430. The difference in pneumonia/CLD events was confined to the infants with the higher half of the pulmonary scores (10.6% in the conventional arm vs 18.7% in the supplemental arm; $P = .051$) and did not differ among the infants with the lower half of the pulmonary scores (6.5% in the conventional arm vs 6.8% in the supplemental arm; $P = .93$; data not in table). Rehospitalization rates for pulmonary causes (excluding for apnea alone), and death rates from pulmonary causes were similar in the 2 arms (Table 6). However, at the 3-month examination (50 weeks' PMA), more infants in the supplemental arm remained hospitalized (12.7% vs 6.8%; $P = .012$), on oxygen (46.8% vs 37.0%; $P = .020$), and on diuretics (35.8% vs 24.4%; $P = .002$). The proportion of infants who experienced any 1 or more of these adverse pulmonary events by 3 months' corrected age as defined by remaining hospitalized, remaining on study equipment, oxygen, steroids, methylxanthines, or diuretics was significantly higher in the supplemental arm than in the conventional arm (57% vs 46%, respectively; $P = .005$). Regression analysis adjusting for the important baseline covariates of race, ROP severity, gestational age, and pulmonary status did not change the significance of these findings.

Adverse events from sepsis without pneumonia did not differ between the 2 arms, and survival through the 3-month examination was similar (97.8% conventional vs 97.2% supplemental). Mean PMA at discharge for those infants going home was the same in both arms at 41 ± 3 weeks (range: 35–56), and infants in both arms were able to take oral feeds without a gastric tube at the mean PMA of 39 weeks. At the 3-month follow-up examination, developmental levels as assessed by the Revised Parental Denver Questionnaire were similar (equivalent ages = 3.5 ± 1.4 months in the conventional arm vs 3.4 ± 1.4 months in the supplemental arm).

DISCUSSION

These findings demonstrate that supplemental oxygen, as used in this study for prethreshold ROP, did not significantly decrease the proportion of infants who have at least 1 eye progress to threshold ROP, although the differences were close to nominal statistical significance. Using the observed conventional progression rate of 48%, the study has a power of 70% against a 10-percentage point absolute difference, and a power of 98% against a one third reduction, adjusting for the use of repeated interim analyses as described above. The resultant power is lower than expected because the adverse ophthalmic outcome rate in the conventional group was higher than expected.

TABLE 6. Pediatric Outcomes Between Randomization and Three Months' Corrected Age*

	Conventional $n = 325$	Supplemental $n = 324$
Event occurring after randomization		
Weight gain over the first 2 wk (g; mean ± standard deviation)	291 ± 137	278 ± 143
Length gain over the first 2 wk (cm; mean ± standard deviation)	1.8 ± 1.8	1.7 ± 2.0
Head circumference increase the 1st 2 wk (cm; mean ± standard deviation)	1.6 ± 1.0	1.4 ± .9
PMA at discharge home† (wk; mean ± standard deviation)	41.1 ± 3.3	41.3 ± 3.4
PMA to achieve oral feeding‡ (wk; mean ± standard deviation)	39.0 ± 3.5	38.9 ± 3.6
Infants with pneumonia/CLD events (total # of events)§	25 (29)	38 (51)
Infants with sepsis, but no pneumonia/CLD (total # events)	12 (12)	11 (11)
Infants with apnea/bradys triple baseline (total # events)	26 (36)	30 (33)
Outcomes at the 3-month corrected age window‖		
Remained hospitalized¶ (%)	6.8%	12.7%
Remained on study equipment (%)	3.1%	3.4%
Remained on oxygen (%)	37.3%	46.8%
Remained on steroids (%)	12.5%	14.2%
Remained on methylxanthines (%)	13.5%	14.7%
Remained on diuretics (%)	24.4%	35.8%
Infants with any 1 of the above, # of infants (%)#	148 (45.5%)	183 (56.5%)
Outcomes at 3 months' corrected age examination	$n = 301$	$n = 302$
Infants rehospitalized (# of all rehospitalizations)	99 (132)	87 (116)
Infants rehospitalized for pulmonary reasons, not apnea (# of all rehospitalizations)	46 (53)	41 (49)
All deaths, *n* (pulmonary cause of death, *n*)	7 (3)	9 (5)
Room air saturations too low to test, *n* (%)	17 (6%)	35 (12%)
Room air oxygen saturation for those tested, mean ± standard deviation	95.3 ± 4.7%	94.6 ± 7.7%
Weight gain from randomization (mean ± standard deviation; kg)	2.96 ± 1.00	2.88 ± 1.05
R-PDQ developmental level** (mean ± standard deviation; mo)	3.5 ± 1.4	3.4 ± 1.4

* Corrected age indicates months after the date an infant should have been born at full term (3 months' corrected = 52 weeks' PMA).
† Limited to infants who were discharged to home (ie, excludes deaths, loss to follow-up, and those remaining hospitalized at the 3-month examination).
‡ Excludes 16 conventional and 33 supplemental infants who were not yet feeding by mouth by 50 weeks' PMA, 2 conventional and 7 supplemental infants who died before oral feeds, and 6 conventional and 7 supplemental infants with incomplete data. Oral feeds means that the infant was taking all enteral feedings by nipple (bottle or breast).
§ Excludes 30 conventional and 36 supplemental infants recruited early in the trial for whom these data were not collected.
‖ The 3-month corrected age window was a target of 12 ± 2 weeks after due date, or 50 to 54 weeks' PMA. Outcomes are reported as of 50 weeks' PMA to permit comparisons as some infants were examined late in the window or outside this window.
¶ Values exclude 31 infants with missing data at 50 weeks' PMA attributable to loss to follow-up (14 conventional and 17 supplemental).
# Number of infants, and percent of all enrollees represented by any 1 or more of the 3-month events.
** R-PDQ indicates the Revised Parental Denver Questionnaire.[26]

In STOP-ROP, the observed rate of progression from prethreshold to threshold (48%) in the conventional arm is higher than reported in the CRYO-ROP study (33%) for a number of reasons that can be identified. The eligibility criteria for STOP-ROP excluded nearly half of the infants who would have been included in the CRYO-ROP study, and these were the ones that did not require oxygen and had less severe lung disease at the time of prethreshold ROP. The STOP-ROP enrollees had lower birth weights than the CRYO-ROP infants (726 g in STOP-ROP vs ~850 g for CRYO-ROP prethreshold).[1] During the CRYO-ROP study, borderline threshold cases were judged as not threshold, to avoid treating eyes with an unproven intervention. Because peripheral ablation has been demonstrated to be effective for threshold ROP, this is no longer true, and as in clinical practice, the STOP-ROP study judged in favor of the diagnosis of threshold disease in borderline cases. Finally, the differences in the STOP-ROP definition of threshold ROP in zone I (see Table 1) would result in more infants being diagnosed with threshold ROP during the STOP-ROP trial.

The STOP-ROP results differ from the 2 smaller case series in the literature in which supplemental oxygen for infants with prethreshold ROP was associated with a high regression rate of prethreshold ROP without the need for ablative retinal surgery.[28,29] Some of the possible explanations are differences in patient selection, level of oxygen administration, timing of the intervention, and use of historical controls in the case series. Infants in these case series may have had milder ROP than those enrolled in STOP-ROP, and the effect of that would be higher progression rates in STOP-ROP. The average birth weight of the infants in that series was 814 g, heavier than the 726-g average birth weight of infants enrolled in STOP-ROP, and therefore, at lower risk for severe ROP. In the Gaynon et al[28] series, if infants were mostly detected as having pretheshold ROP before developing plus disease, the findings in that series and the subgroup of infants in STOP-ROP without plus disease would be more consistent. Large differences in reported improvements between historically controlled case series and randomized trials are well recognized and are usually attributed to changes in several aspects of medical care over time, as well as patient selection. STOP-ROP expended considerable effort to maximize the time infants were in their targeted ranges of saturation and not at saturation levels of 100%. In contrast, however, the saturation targets were "a minimum of 99%" in the Gaynon et al study,[28] and "a minimum of 98%" in the Seiberth et

al report.[29] Thus, infants in those 2 series probably had higher average saturation levels than the STOP-ROP supplemental group. To compare the target range of the supplemental arm in STOP-ROP as measured by the Ohmeda 3740 oximeter with these other 2 studies, it could be argued that 1.6 saturation points should be added to the STOP-ROP range to make the saturation monitor readings equivalent. If this is done, the STOP-ROP supplemental range becomes 97.6% to 100% saturation, even closer to the reported series and, therefore, not an explanation of differences.

Another alternative explanation may be in the timing of treatment. If immediate application of the supplemental oxygen at prethreshold diagnosis would provide maximum benefit, it could be argued that use in standard practice would result in earlier and possibly more effective treatment of eyes with prethreshold ROP. Gaynon reports (D. L. Phelps, personal communication, October 1999) that ROP screening was performed at weekly intervals in their series, which could be expected to reduce the number of infants reaching plus disease before beginning oxygen treatment. Screening examinations before prethreshold identification were usually performed every 2 weeks in the STOP-ROP centers, consistent with the AAP recommendations. In addition, the process of obtaining both an independent confirming examination and informed consent of the family or guardians resulted in delays between the first time that prethreshold ROP was observed and the start of the study intervention. In approximately one quarter of the cases, this was >48 hours.

Oxygen requirements go up by ~5 to 9 percentage points when changing to supplemental oxygen from the conventional range, emphasizing that infants truly receive more oxygen when assigned to the supplemental arm. We had not expected that pulmonary events of pneumonia and/or CLD exacerbations were going to be 1.8 times more likely to occur in the supplemental arm. The absolute increase in acute pulmonary events of 7.3% gives a number-needed-to-treat calculation of 1 more pneumonia/CLD episode for each 13.7 infants treated with supplemental oxygen. The ROP progression data give a number-needed-to-treat of 13.2 infants to prevent 1 case of progression to threshold ROP. By this analysis, one could expect ~1 episode of pneumonia/CLD exacerbation for each case of peripheral ablative surgery that might be prevented. That might be regarded as a reasonable trade-off by most neonatologists and ophthalmologists, but the condition of the infants at 3 months' corrected age must also be considered. At that time, 97% of subjects were off the study assigned treatments, and those in the supplemental arm continued to need more oxygen and diuretics, and a greater number remained hospitalized. Our data suggest that the magnitude of any benefit from supplemental oxygen in reducing the need for surgery is likely to be on the order of 7% to 14%, with no reduction in the number of retinal detachments. The potential long-term advantage of avoiding peripheral ablative surgery for ROP is unknown, but to the extent long-term side effects might occur, even a small reduction in surgery rates may be of value. The potential long-term effects, both of costs and to the families, of prolonging hospitalization from worsened lung disease also should be considered.

Our original hypothesis was not only that supplemental oxygen would prove beneficial for the eyes of infants with prethreshold ROP whose pulse oximetry in room air is <94%, but in addition, that it would be beneficial for CLD, resulting in better growth and lower pulmonary vascular resistance.[39,40] However, Supplemental oxygen at a target range of 96% to 99% saturation seemed to have deleterious effects on CLD in some infants, with no change in growth or neuromotor development. Previous reports of an improvement in weight gain and resolution of cor pulmonale with oxygen supplementation could be explained if saturation levels in the control infants of those studies were even lower than the STOP-ROP conventional range. This is certainly possible, because those reports date from periods preceding the routine availability of continuous pulse oximetry. Fortunately, others are investigating this question in a carefully controlled randomized trial in Australia. The Benefits of Oxygen Saturation Targeting Trial is currently enrolling infants in a test of the safety and efficacy of supplemental oxygen for infants with CLD. ROP is not an entry criterion in that study, but will be examined as a secondary outcome (D. Henderson-Smart, personal communication, 1999).

These results provide valuable data for the clinician. The STOP-ROP data clearly demonstrate that oxygen, at saturation levels of 96% to 99% does not increase the severity of ROP in the eyes of infants with prethreshold ROP, even in the 123 eyes with ROP of less than pretheshold severity at randomization. There are no data, however, to suggest that the higher saturation levels are safe for the early immature eye that does not yet have established ROP. The reported data apply only to infants who are well beyond the initial weeks after birth and must not be interpreted as showing safety of supplemental levels of oxygen at younger ages.

The present study does not rule out a potential small reduction in the rate of ROP progression with supplemental oxygen, and a subgroup analysis suggests that supplemental oxygen, as used in this study, may be more effective in pretheshold ROP without plus disease. However, secondary analyses, not prespecified, must be cautiously interpreted and require additional study. The predictive value of various possible definitions of prethreshold ROP have not been systematically studied and reported but could prove very important and should be investigated. The data show a modest deleterious effect of supplemental oxygen on CLD in some infants with more severe lung disease at baseline. Therefore, clinicians must consider which patients might tolerate the added pulmonary risk of supplemental oxygen as a therapeutic intervention for their ROP. If an infant requires saturations of 96% to 99% for cardiopulmonary reasons, fear about causing worse ROP is not a reason to withhold the oxygen. Results from other studies, such as the Benefits of Oxygen Satura-

tion Targeting Trial, may help further our understanding of the effects of supplemental oxygen in infants with CLD.

ACKNOWLEDGMENTS

STOP-ROP was supported by grants from the National Eye Institute, the National Institute of Child Health and Human Development, the National Institute of Nursing Research, several National Institutes of Health General Clinical Research Centers, and local funding sources at many centers. These included: in Rochester, NY, The Delta Gamma Sorority, the Rhea and Raymond White donation, and Research to Prevent Blindness; Boston, MA, support for home oxygen provided by Chartwell Home Therapy, and the New England Medical Center received support from the National Institutes of Health General Clinical Research Center Grant M01-RR00054; and Stanford University received additional support from National Institutes of Health RR 00 070 and National Institutes of Health HD 27 880.

We are indebted to the families who allowed their infants to participate in the STOP-ROP trial, and the dedicated and patient nurses in 71 newborn intensive care units who worked so hard to keep infants within the study target ranges. The Ohmeda Corporation kindly donated the pulse oximeters, and training on their use for all the study centers. We thank Velma Dobson, PhD, for her critical review of the draft manuscript, and Randy Taft of ProFox, Inc, for helping us to develop the laptop computer program that provided feedback on the oximetry.

APPENDIX: THE STOP-ROP PARTICIPATING CENTERS AND MAJOR COMMITTEES

Permanent Executive Committee

Chair: Dale L. Phelps, MD; Members: Anne Lindblad, PhD; J. David Bradford, MD; Nancy E. Wood, CCRA; Neal L. Oden, PhD; Cynthia Cole, MD; Brenda MacKinnon, RNC; Anita Yaffe, MSN, MPH; Donald F. Everett, MA; Linda Wright, MD; Cara Krulewitch, CNM, PhD; Additional Writing Committee Members: Beverly S. Brozanski, MD; Terri Young, MD; Mark Scott, MD

Data and Safety and Monitoring Committee

Chair: Barbara S. Hawkins, PhD; Members: Colin B. Begg, PhD; Edward F. Bell, MD; Edward G. Buckley, MD; William W. Hay, MD; Burton J. Kushner, MD; Linda Snouck-Hurgronje, RN, MS; Carol R. Taylor, CSFN

Data Coordinating Center

Principal Investigator: Neal L. Oden, PhD; Anne S. Lindblad, PhD; Co-investigators: Christine Bachy, BS; Stuart H. Berlin, BS; Diane Brandt, BS; Marsha Guzzey, MLT; Linda Henson; Bernadette Jolles, MA; Elaine Stine; Carol Thomas-Sharp, MS, RN; Judith Van Lare; Anita Yaffe, MSN, MPH

Boston Consortium: New England Medical Center, Boston City Hospital, Children's Hospital, Brigham and Women's Hospital, Beth Israel Deaconess Medical Center, Beverly Hospital, Salem Hospital, South Shore Hospital, Good Samaritan Hospital, Newton Wellesley Hospital, Winchester Hospital, Lowell General Hospital. Principal Investigator: Cynthia Cole, MD; Jane Stewart, MD; Co-investigators: Brenda MacKinnon, RNC; Tracey Alexander, RN; Charles Anderson, MD; Mohammed Ashrafzadeh, MD; Caroline Baumal, MD; Amita Bhatt, MD; Richard Blocker, MD; Elizabeth Brown, MD; Mario Cordova, MD; Mark P. Dacey, MD; Jay Duker, MD; Janine Eagle, MD; Eric Eichenwald, MD; Christy Faherty, RN; Alan Fujii, MD; James Gray, MD; Mary Elizabeth Hartnett, MD; Karen Harvey-Wilkes, MD; Julie Hetrick, RN; Mark Hughes, MD; Michael Ip, MD; Susan Izatt, MD; Robert Lacy, MD; Joseph Levy, MD; Thomas Margolis, MD; Karen R. McAlmon, MD; O'Ine McCabe, MD; Maryanne Moore, RN; John Niffenegger, MD; Sam Nikou, MD; Robert Petersen, MD; Kevin Petit, MD; Eric A. Pierce, MD; Bill Powers, MD; Maureen Pursley, RN; Elias Reichel, MD; Leon Remis, MD; Mark Rivellese, MD; Barbara Ann Shephard, MD; Jeffrey Sorkin, MD; Ann Stark, MD; Susan Struzik, RN; Tai Tran, MD; Deborah K. VanderVeen, MD; Patricia Vreeland, RT; Richard Wilker, MD; John Wright, MD; Vivian Kim, MD; Vinay Desai, MD; Bryan Rutledge, MD

Columbus: Columbus Childrens Hospital, Ohio State University, Grant Medical Center, Mount Carmel Medical Center. Principal Investigator: Richard E. McClead, MD; Co-investigators: Rae Fellows, MEd; Marci Biel, RNC; Don L. Bremer, MD; Rosalind Maddox, RRT; Brenda Mann, RNC, BSN; Mary Lou McGregor, MD; Christina Nye, MD; Phyllis Peterman, RT; Gary L. Rogers, MD; Ellen M. Rosenberg, MD; John Seguin, MD; Sue Stephen, RN, MS; Craig W. Anderson, MD; Leandro Cordero, MD

Philadelphia: Thomas Jefferson University, Childrens Hospital of Philadelphia, Hospital of the University of Pennsylvania, Albert Einstein Medical Center, Medical Center of Delaware. Principal Investigator: Alan R. Spitzer, MD; Co-investigators: Linda Corcoran, RN; Jim Cullen, RN; Josh Fosnot, BA; Shobhana Desai, MD; Jane Fricko, RN; Joan Giannetta, RN; Mary Catherine Harris, MD; David Hepps, BA; Richard Hertle, MD; Bill Holt, RTT, RN; Kathy Leef; J. Arch McNamara, MD; Dennis Miller, BA; Kathy Mooney, RN; Michael Naidoff, MD; Jeanette R Pleasure, MD; Rachael Porat, MD; Graham Quinn, MD; Terri Saunders, David Schaffer, MD; Michael Spear, MD; Susan Spinner, MSN; William Tasman, MD; James Franklin Vander, MD; Martin Wilson, MD; Sharon Zirin, RN

University of Arkansas: Arkansas Childrens Hospital, University of Arkansas. Principal Investigator: J. David Bradford, MD; Co-investigators: Peggy Ables, RN; Cynthia Bonner, MD; Michael Brodsky, MD; Erin Davis, RN, NNP; Kristie Frost, RN, NNP; Richard W. Hall, MD; Richard Harper, MD; Billy R. Thomas, MD

University of Louisville: University of Louisville, Nortons Hospital, Kosair Childrens Hospital. Principal Investigator: Charles C. Barr, MD; Co-investigators: David Adamkin, MD; Craig H.Douglas, MD; Peggy H. Fishman, MD; Nan Hamlyn-Forti, BSN; Tony Hilbert, John Roberts, MD; Greg Whittington, PsyS;. Judy Wright, BSN

Brown University. Principal Investigator: William Oh, MD; Co-investigators: Nancy Adams, RN; Dawn Andrews, RN; Arthur I. Geltzer, MD; Angelita Hensman, RN; Sue Philo-Heroux, RN; Robert W. Rothstein, MD; Lori Snady-McCoy, MD

Emory University: Crawford Long Hospital, Grady Memorial Hospital. Principal Investigator: Barbara Stoll, MD; Co-investigators: Antonio Capone, MD; Ann D. Critz, MD; Arlene V. Drack, MD; Cathy H. Goulding, RN; Daniel F. Martin, MD; Timothy W. Olsen, MD; Paul Sternberg, MD; Mary Beth White, RN

---

Hello Everyone

We got some new FiO2 data that I had asked Marie to run – somewhat of a gamble – but I think it paid off – The 85-89% infants have an absolute 10% increase (36% vs 26%) in room air during the first 14 days compared to the 91-95% group. I have also decided that we should lower the high alarm 1% to 94% as this will force the 85-89% infants more into the range. For the 91-95% infants, once their oximeter is more than 92 reading they are at 95% and if we want to reduce their time > 95% this would work. Plus I think we want an iron-clad response to the DSMC and thus should do everything possible to convince them to allow this study to proceed.

Please review this and let me know if you are OK with the current letter and response.

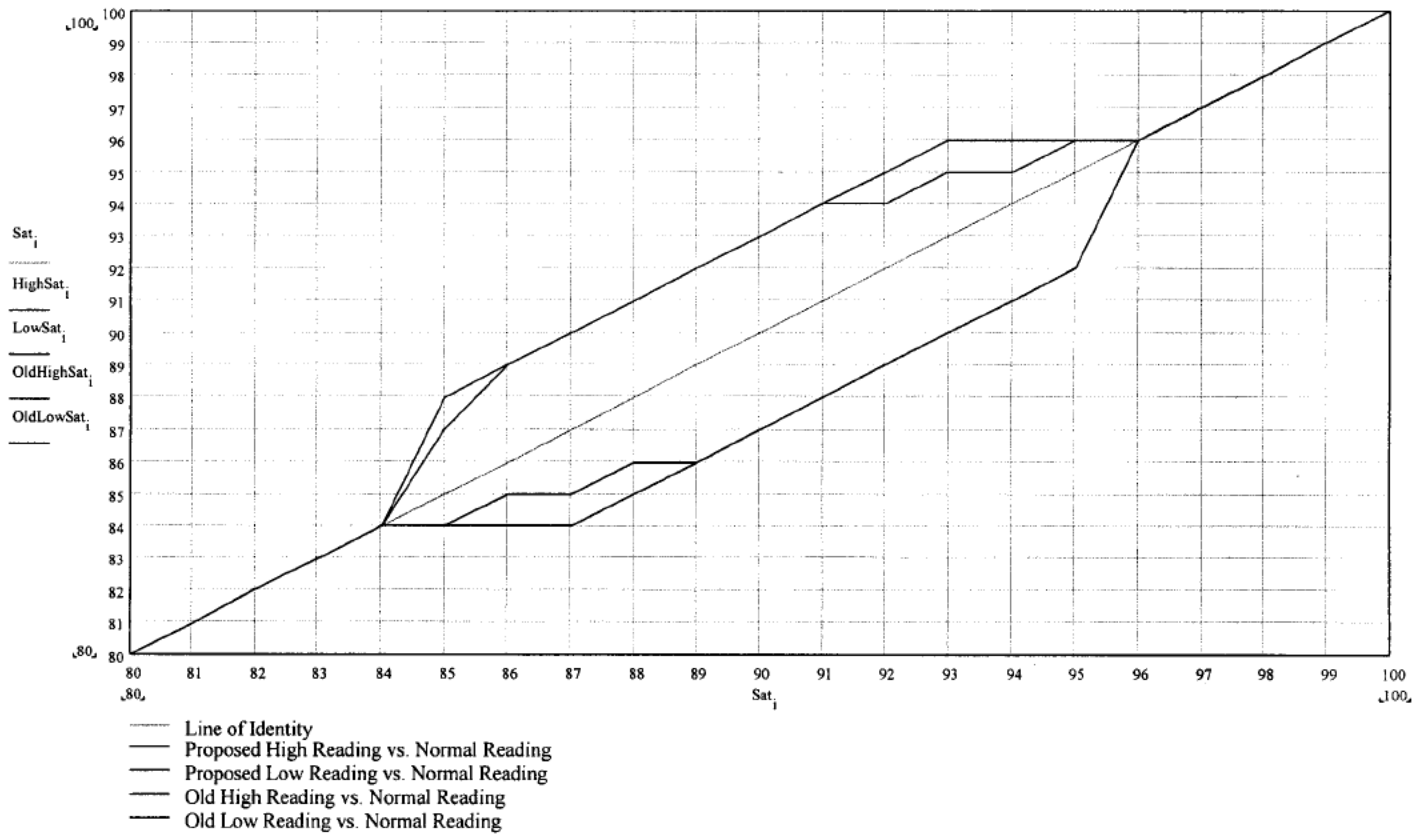
I would like to allow Betty to send all this to the DSMC tomorrow morning.

Thanks for taking the time to consider these issues.

Neil

Converting Actual Readings to Low and High Readings

Actual Reading	To Low Reading	To High Reading
	85% -89%	91%-95%
100	100	100
99	99	99
98	98	98
97	97	97
96	96	96
95	92	96
94	91	96
93	90	96
92	89	95
91	88	94
90	87	93
89	86	92
88	85	91
87	84	90
86	84	89
85	84	88
84	84	84
83	83	83
82	82	82
81	81	81
80	80	80
etc	etc	etc



The Low, Actual & High Reading oximeters synchronize for values greater than or equal to 96 % and less than or equal to 84 %.

In the Actual range of 87 % to 95 %, the Low Reading Oximeter displays a value 3 points below actual.

In the Actual range of 85 % to 93 %, the High Reading Oximeter displays a value 3 points above actual.

Converting Low Readings to Normal Readings

91% - 95%

Low Reading	To Normal Reading
100	100
99	99
98	98
97	97
96	96
95	95.75

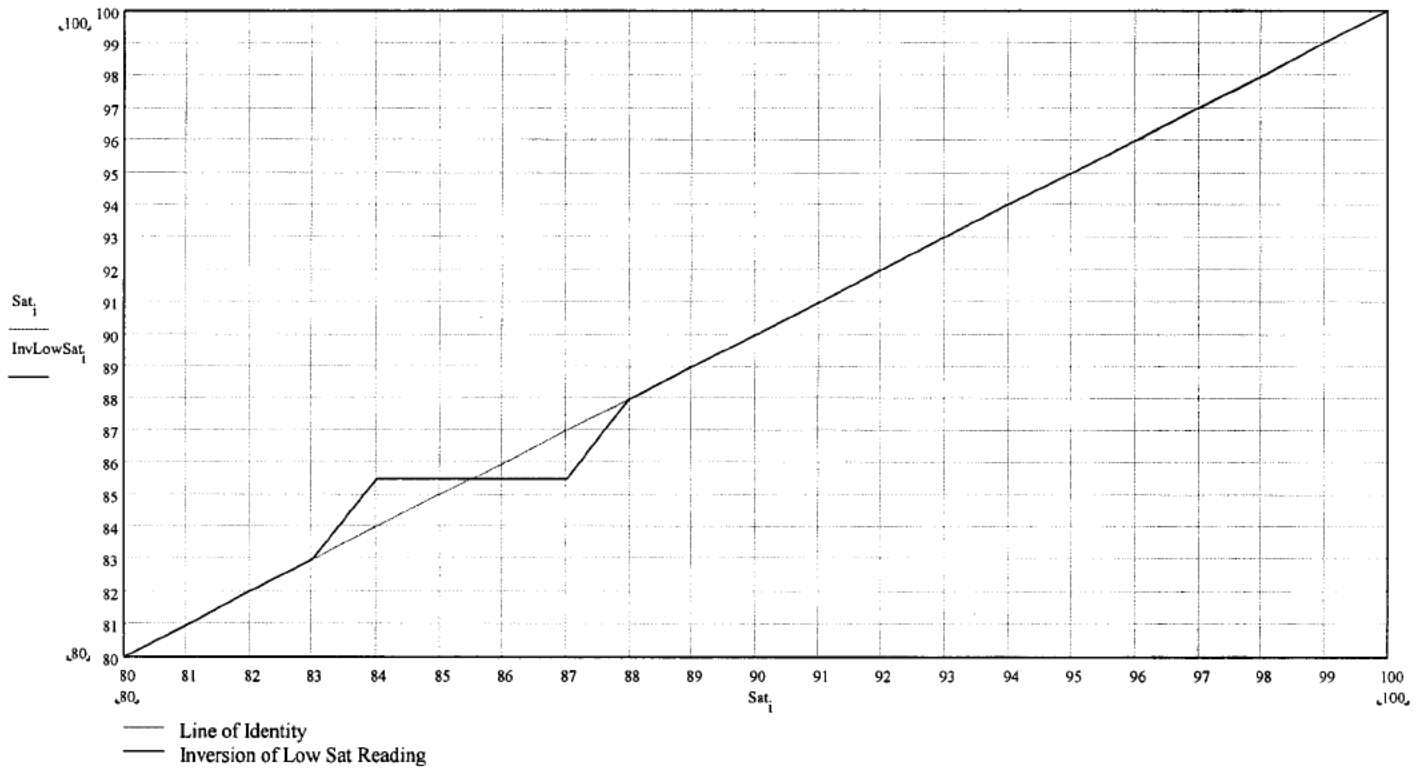
86	89
85	88
84	85.5
83	83
82	82
81	81
80	80
etc	etc

Applying the above inversion yields the following performance:



The inversion has no error above and below an actual reading of 88 % and 83 %, respectively. In between these limits, the inversion error does not exceed 1.5 %. Subjects are typically kept in the region of 91 % (88 % + 3 %) to 95 % (92 % + 3 %).

Converting High Readings to Actual Readings

85% - 89%

High Reading	To Actual Reading
100	100

In response to the comments and concerns of the DSMC, the SUPPORT committee held a conference call Monday Nov 28th at 10:00 to 1130AM to prepare a response. This issue and the preparation of a response was then discussed by the entire NICHD Neonatal Research Network Steering Committee in a conference call held Wednesday. Nov 30th at 9:30 – 11:00 AM. This response has been reviewed by the SUPPORT Subcommittee, and subsequently by the Steering Committee, and reflects the input of all NICHD Principal Investigators.

- The DSMC made the following 2 comments in their letter regarding the SUPPORT trial. This was generated after they reviewed the oximeter data, which was corrected back to actual SpO2 values from the altered values displayed at the bedside:

1. There is a significant safety and exposure issue for the infants in the high saturation treatment group because an unacceptably high proportion of time was spent by these study subjects in the >95% range

2. There is a futility concern for this arm of the trial in that there does not appear to be substantial separation between the two high and low saturation treatment groups, and the babies are not being kept in the target range the appropriate amount of time in order to meaningfully test the oxygen saturation intervention as originally designed.

Based on these two issues, the consensus of the Committee was to recommend stopping the oxygen saturation arms of the SUPPORT trial due to safety and futility concerns.

We have responded to each of these concerns and our responses are detailed below

Response to Issue Number 1

We appreciate the concern expressed by the DSMC regarding a potential safety issue secondary to durations of SpO2 values greater than 95%.

1. Review of existing evidence and practice regarding durations of higher SpO2 values:

To date there are no prospective data which define the SpO2s experienced by the ELBW infant from birth as part of usual clinical care. Because no published studies have evaluated the effects of different target SpO2 ranges from birth on important outcomes, this was one of the principle reasons for the design and conduct of the SUPPORT trial.

A number of studies have evaluated different alarm limits, but have not reported the actual durations of SpO2 in the various ranges. Nghiem et al in a PAS abstract this year reported that nurses caring for ELBW infants believe that an acceptable oxygen saturation range should include higher upper limits than

specified by current policy (Nghiem et al, Nursing Opinions and Practices of Oxygenation in Prematures: The NOPOP Study PAS #3415, 2005). The study by Hagadorn reported as a late breaker at the PAS last year (Hagadorn et al, Actual vs Intended Pulse Oxygen Saturation (SpO2) in Infants <28 Weeks Gestation. PAS 2004, Attached) did report on the experience of monitoring the actual SpO2 for 72 hours in the first 4 weeks of life in 78 ELBW infants. They reported that the "lower limits of intended ranges at study centers varied between 83-92%, upper limits 92-98%. Infants were monitored for a median of 70 hours (25th-75th percentiles 67-71 hr) during each of the first 24 weeks. Overall median SpO2 for infants on supplemental O2 during the first 4 weeks was 95% (25th-75th percentiles 91-97%; range of study center medians 91-96%. Centers ranged between 16-71% compliance with their individual intended SpO2 range. Most noncompliance was above intended range." In comparing the SUPPORT data evaluated to date by the DSMC, it is of interest that the mean SpO2 in the 2 Oximeter arms is 90% and 92%, with medians of 92% and 94%, all of which are below that reported by Hagadorn et al (median=95).

The 2 other relevant trials, STOP-ROP and BOOST, both enrolled infants of > 32 weeks postmenstrual age (PMA), and maintained 2 levels of SpO2, 89% to 94% and 91-94% versus 95% to 98% and 96% to 99%, by administration of oxygen. These studies achieved reasonable separation, but did demonstrate substantial overlap of the intended ranges (estimated to be 50% or greater, D Phelps, PI for STOP-ROP). It is important to note that these studies were testing two ranges both of which were higher than the lower range of the SUPPORT trial (85% to 89%) and were treating infants who, for the most part, had recovered from their acute disease. In the BOOST trial 70% of the enrolled infants were < 28 weeks of age at birth (all of SUPPORT is < 28 weeks), 32 weeks PMA, and required oxygen at enrollment (Askie et al, New England Journal of Medicine. 2003; 349(10):959-967). The STOP-ROP trial enrolled infants with pre-threshold ROP at a PMA of 35.4 + 2.5 weeks of age (Phelps et al, Pediatrics. 2000; 105(2):295-310). These trials then gave the higher SpO2 range infants additional oxygen to increase their SpO2 to the desired range. STOP-ROP reported that the infants in the high range had an SpO2 > 95% for > 97% of the monitored time. These studies found an overall increase in pulmonary morbidity in the higher SpO2 range infants.

Examination of oximeter data from one of the NRN sites (Case Western, Walsh et al) obtained for an ongoing study evaluating infants similar to those enrolled in SUPPORT, and managed with conventional oximeters, revealed that for the 9 infants for whom results were available that the percentage of time with and SpO2 > 95% was > 50%.

2. Impact of SUPPORT oximeters algorithm on sat values:

The oximetry algorithm that was designed for the SUPPORT trial is such that re-conversion of the altered oximeter values does not result in a discrete SpO2 number for every displayed value. SpO2 values, of 93%, 94% 95% and 96% will all be reconverted to a single value. As an example, when the actual percent of time at each individual SpO2 point was calculated for this review, in

the 91% to 95% group, there was 5.76% of the time spent at an actual SpO2 of 96% and 8.38% of the time spent at values that represented conversion from readings of 93% to 95%. In the 85% to 89% arm, values of 84%, 85%, 86% and 87% will be reconverted to a single value of 84%. This is a result of having the displayed values return to non-skewed SpO2 values at < 84% and > 96%, a safety design felt to be important by all involved in this trial (See Attached file USCD1). Thus the percentages reported to the DSMC for some of the ranges that include these values were not an accurate representation of the true values. However all values > 96% and < 84% are actual and do not require any conversion.

Percent of time of spent at SpO2 < 84% and > 96%
(RTI, Dec 2, 2005)

Range **Assigned**	High target (91-95)	Low target (85-89)
< 84%	8.30	14.05
> 96%	21.45	15.47

In the current SUPPORT study, an initial analyses utilizing only unaltered SpO2 values as shown above , ie those below 84% and above 96%, have shown that one arm had an SpO2 > 96% for 15.47% versus 21.45% of the time for the comparison arm, and the duration of an SpO2 < 84% was also different at 14.05% versus 8.30%. The values for SpO2s > 96% using unaltered data suggests that the SUPPORT trial to date has, if anything, reduced the duration of higher oxygen saturations.

In addition, analyses using only actual SpO2 demonstrate that the infants in this trial who are receiving supplemental oxygen are spending approximately 70% of the time with a true SpO2 value between 84% and 96%. We believe that this is information is very encouraging.

3. Impact of inclusion of data from periods in room air on saturation distributions:

As part of the SUPPORT trial, we collect information about inhaled oxygen concentration 3 times a day for the first 14 days and daily thereafter. We believe that an improved documentation of the times when infants are on room air will allow us to determine the saturations during actual oxygen exposure. At the present an infant is considered to be receiving supplemental oxygen if he/she requires oxygen for greater than 2 hours. This results in infants being categorized as receiving supplemental oxygen for significant periods when they are actually in room air. This would result in durations of SpO2 greater than 95% that were felt to be modifiable and reported as such when in fact there is no effective treatment for such elevated SpO2s. In addition, we do not know if such SpO2s on room air are associated with any morbidity. From the SUPPORT study data analyses to date we know that infants in room air have SpO2s > 95% for 46% to 69% of the time. By using only information for actual SpO2 values of

96%, we have determined that the infants in the 91%-95% group had a duration at an SpO2 of 96% of 6.68%, and a total duration of 96% or greater of 28.13%.

In view of this design, we would suggest that all future interval analyses for safety examine the ranges of <84% and >96% and consider those ranges for review of low and high durations of SpO2.

We believe that the SUPPORT trial will actually define the periods of time that ELBW infants spend with different ranges of SpO2, and that it is essential to collect this information. In addition, as our findings indicate a lower true percent of the time at SpO2 values >95%, and lower median SpO2 values than has previously been reported, we are in fact, reducing the time with high SpO2 values compared to usual care. The SUPPORT trial carefully evaluates risks, and we will be evaluating group differences for all important short and long term outcomes.

The SUPPORT trial methodology actively encourages all caretakers to keep SpO2 < 96% by having alarm limits set at 85% and 95%. These limits were utilized because it was felt that these represented current practice, and there are no studies which have provided information regarding durations of SpO2 below 85% and subsequent outcomes. While we have had substantial discussion about decreasing the lower alarm limit to below 84%, we are reluctant to make such a recommendation in view of the likely resultant increases in durations of SpO2 below 84%. It is difficult to lower the current high alarm limit of 95% as the 91%-95% group would be alarming when still in target range. The oximetry algorithms were designed to keep infants in the narrower target range of 88% to 92% with the realization that setting alarm limits at these values would severely increase the frequency of the alarms sounding. Nevertheless, our results to date suggest that we have decreased the expected percent of time > 95%, and in one group the value of 14% may be as low as is achievable in an actual clinical environment given the evidence provided by Hagadorn et al and Nghiem et al. In addition a preliminary analysis of the FiO2 exposure of the 2 oximeter groups has demonstrated that the 85% - 89% group have a substantially decreased exposure to oxygen compared to the 91% - 95% group. (See below)

We believe the SUPPORT study will define the distribution and durations of pulse oximetry values among premature infants in highly staffed, dedicated academic centers, and among infants randomized to two different target ranges. For this reason alone, the SUPPORT trial will be very valuable. All of the procedures outlined below in response to your second concern will also allow us to further increase the percentage of time that the infants are in the maximally altered SpO2 ranges which we believe will further increase separation of these groups.

Response to Issue Number 2

There is concern that we have not achieved adequate separation by the current oximeters and study personnel.

1. As described above, the results of additional analyses performed in response to the concerns of the DSMC show differences in the durations of low and high SpO2s between the 2 oximeter groups, but lesser differences in the narrower target ranges. A careful analysis of the most recent converted values demonstrates that the cumulative time spent with an SpO2 of 90% or less is 24.0% (91% - 95%) versus 39.5% (85% - 89%). In addition, the 91% -95% group spend 40% of the time in that narrow range which may represent the achievable target duration for the narrow target range. The 85% - 89% oximeter group spends 18% of the time in their narrow target. One obvious reason for this difference is that when the 91%-95% group exceeds the high end of the range, the oximeter alarms, whereas this does not occur for the high end of the lower range infants.

We have now had an opportunity to review the actual FiO2 exposure of the 2 oximeter groups and that analysis is attached (Daily FiO2 for first 14 days). This analysis has shown that the infants in 85% - 89% group spend approximately 10% more time in room air in the first 14 days than infants in the 91% - 95% group (35.5% vs 26.6%). We do not at the present time have any comparative data for similar populations of ELBW infants, and the actual significance of these differences will only become apparent when the trial is completed.

2. We do acknowledge that it would be desirable to increase the percentage of time in the narrower target range and towards this end would propose the following changes to SUPPORT:

A. We will **change the high alarm to 94% to further assist in keeping the 85%- 89% group more in target and reduce the durations of SpO2 > 95% in the 91% - 95% group**. This change should improve our time in the narrow target ranges and further separate our 2 oximeter groups. For the 91%-95% group, at present when the study oximeter reads greater than 92%, the actual SpO2 is at 95%. This will result in more frequent high alarms for this group, the result of which will be to reduce the durations of higher SpO2s.

B. We will require **documentation that the oximeters alarm limits are set and functional as per protocol every 4-6 hours**. We have found that in some units the high alarms are being turned off, and thus believe that such documentation will greatly assist in decreasing the actual time that the SpO2 is > 96%. This task will be assigned to the most appropriate personnel in each unit, which may include bedside or research nurses or respiratory therapists, and this procedure is already being done in many NRN units.

C. We will immediately initiate a **change in our data collection for FiO2 to ensure that subsequent interval reports more accurately reflect saturations measured while on oxygen therapy and exclude saturations of infants in room air.** We will change the data form to indicate that the infant was either in oxygen for the entire 24 hours, and if not, will provide a more accurate estimate of the true time in oxygen, and we will continue with this form of data collection for the entire time that the infant is receiving oxygen. In the current protocol we

collect such information 3 times a day for the first 14 days only and then daily thereafter. We believe that more frequent and extended documentation will allow us to determine more accurately the actual time that an infant is in room air. At the present the infant is considered to have spent a day in oxygen if he/she requires oxygen for greater than 2 hours. This results in infants being categorized in oxygen for significant periods when they are in room air. While in room air, we cannot manipulate the SpO2, and thus knowledge of the true time in oxygen will produce a more accurate representation of oximetry results that are subject to care interventions.

D. We will initiate **further training and in-service, and a change to the protocol to stress the importance of keeping the SpO2 alarms functional and at the limits of 85% and 94%**. In the past these were guidelines, and we will now change the study manual and protocol to indicate these limits are now set by protocol and that violations will be documented. We will encourage all caretakers to aim for an SpO2 value of 90% and make every effort to educate caretakers to make smaller adjustments in FiO2 and ensure that the infant is maintained between the 87% to 93%, the range with the maximal separation of the study oximeters. We will further facilitate the use of the 2 hour and 12 hour histograms showing the infants' actual ranges to provide feedback to the caretakers regarding the percentage of time in the target ranges.

E. We will develop **guidelines for managing desaturations such that the increase in oxygen is proportional to the desaturation**. More modulated increases in oxygen during these desaturation events will minimize overshoot and the potential of high SpO2 values. We would hope that such changes – ie increasing the FiO2 in steps of 5% as opposed to much larger increases will decrease the resultant overshoots creating the high SpO2 values. This will be included in the revised manual of operations.

F. **We will place bedside cards to indicate the desired target range**.

G. We will **initiate compliance monitoring visits coordinated by RTI to visit random sites**. These visits had been planned, but had not yet been initiated. The teams will consist of a member of RTI and a study coordinator, and they will review the adherence to the protocol and any other relevant issues.

H. We would recommend that at a minimum, **the unblinded oximetry data be reviewed again after an additional 100 to 150 infants have been enrolled in this trial.**

We thank the DSMC for their thoughtful concerns. We trust that our plans to move forward with the SUPPORT trial are acceptable to the DSMC. We are anxious to initiate the above changes, seek IRB approvals and re-activate this trial.

Gordon Avery, M.D.
Chairman of the Data Safety Monitoring Committee
NICHD Neonatal Research Network

Dear Dr. Avery,

The SUPPORT Trial Subcommittee and the NICHD Network Steering Committee have reviewed in detail the concerns of the Data Safety Monitoring Committee. We are appreciative of the diligence and thoughtfulness that went into these concerns and we have carefully considered the comments made by the Data Safety Monitoring Committee with respect to both the issue of patient safety and the question of futility relative to the separation of the infants in the two oximetry arms of the trial.

We are very mindful of the need to protect patient safety and toward this end have reviewed the current experience relative to exposure of current ELBW infants to saturations above 95%. There is little information regarding this issue in the literature. We have quoted what we believe to be the relevant recent experiences, including the Network experience with exposures to higher SpO2 ranges. In addition we had asked RTI to provide us with unaltered oximetry data which allows us to look at information for oxygen saturations of 97% or greater and less than 84%, as these values were not altered by the algorithm in place for the study. We also compared the mean and median values of the SpO2 seen in the SUPPORT trial to date with those reported by Hagadorn et al, the only other report that contains such information. This information suggests that our current SpO2 exposures, especially to SpO2 values of 97% and above, for infants within the SUPPORT trial are probably less than is currently being experience outside of the trial, both from the Network experience and in the general practice of neonatology for the ELBW infant. In addition our median SpO2 values for both of our oximetry groups are lower than those reported by Hagadorn et al. An initial evaluation of the FiO2 data does demonstrate that the 85%-89% group requires oxygen for 10% less overall duration than the 91%-95% group, further indicating that these groups are being separated in their clinical management.

We agree that we should aim for greater separation between the oximetry groups, and are pleased that we are seeing some differences on SpO2 and FiO2 exposures between the groups. There is less separation in the target ranges than we desired, and I have detailed our responses to each of the DSMC's concerns in the attached review. We believe that with these changes to the Protocol and Manual of operations and additional in-service at the sites coupled with intermittent site visits, that we will attain an even greater SpO2 separation in all ranges, and differential oxygen exposure for our 2

study groups. We would also like to recommend a re-evaluation of this data after an additional 100-150 infants have been enrolled.

We thank you and your committee for your careful review and suggestions. We hope that our responses are appropriate and that we may be allowed to continue this important trial

Sincerely,

Neil N. Finer, M.D.
Principal Investigator on behalf of the SUPPORT Subcommittee

Hi Rose
I received this email today. I will not discuss the trial with anyone outside the study until we have a final decision about moving ahead.
Any thoughts?
Neil

Dear Neil,
I realize am not up on the progress of SUPPORT.
The comment from Augusta (in the email below) is very important.
If you do not mind sharing, and if Augusta's comment is true, I would like to learn what issues put SUPPORT on hold, and if the issues are relevant to US POST, BOOST, etc.
I am in Wash DC.
Email you have.
Cell: 617-529(b) (6).
I hope you are well.
Look forward to speaking with you.

- Cindy

Hi Rose
I received this email today. I will not discuss the trial with anyone outside the study until we have a final decision about moving ahead.
Any thoughts?
Neil

Importance: High

Dear Neil,
I realize am not up on the progress of SUPPORT.
The comment from Augusta (in the email below) is very important.
If you do not mind sharing, and if Augusta's comment is true, I would like to learn what issues put SUPPORT on hold, and if the issues are relevant to US POST, BOOST, etc.
I am in Wash DC.
Email you have.
Cell: 617-529(b) (6)
I hope you are well.
Look forward to speaking with you.
- Cindy

Attachments:	SUPPORT Trial DSMC Response.ppt Response to DSMC Steering Final2 Dec4.doc

Hi Rose and Everyone

I have asked Marie to do some analyses for FiO2. I think that our response as written in the attached revision - - Dec 4 – is the one that should go forward to the DSMC

I prepared a PowerPoint presentation. Once we see the FiO2 data, we can decide how or if to use them. I would like your opinions as to whether I should use this with the DSMC during the phone call by circulating it to them in advance.

I will be on service this week but will keep close to the email and phone.

Be well

Neil

SUPPORT Trial
Response to the DSMC

December 3 2005

Report of the DSMC Nov 2005

The DSMC expressed 2 concerns:

1. **There is a significant safety and exposure issue for the infants in the high saturation treatment group because an unacceptably high proportion of time was spent by these study subjects in the >95% range**

Report of the DSMC Nov 2005

2. There is a futility concern for this arm of the trial in that there does not appear to be substantial separation between the two high and low saturation treatment groups, and the babies are not being kept in the target range the appropriate amount of time in order to meaningfully test the oxygen saturation intervention as originally designed.

Response to DSMC

Safety Issue of SpO2>95%

Concern regarding safety issue of duration of SpO2 > 95%

- ✓ **The current best data from Hagadorn et al evaluated 78 ELBW infants for 70 hours per week for the first 4 weeks of life**
- ✓ **Lower and upper limits were 83% -92% and 92%-98%**
- ✓ **Median SpO2 = 95%**
- ✓ **Medians from SUPPORT Oximeter groups – 92% and 94%**

Response to DSMC:
Safety Issue of SpO2>95%

- STOP-ROP high treatment infants spent 97% of time > 95%
- Case Western a current NRN Center – Current data from SUPPORT type ELBW infants – SpO2 > 95% for > 50% time
- SUPPPORT Infants on room air – SpO2 > 95% from 46% to 69% of time

Response to DSMC: Safety Issue of SpO2>95%

- **The actual algorithm for conversion of displayed versus actual values results in inability to create a whole value for each displayed value.**
- **We calculated the time that infants were > 96%**

  and < 84%
- **These values may be the first such data for a large group of ELBW infants that has been reported.**
- **These values appear lower than any previous reports**

Response to DSMC: Safety Issue of SpO2>95%

Percent of time of spent at SpO2 < 84% and > 96% (RTI, Dec 2, 2005)

Range Assigned	High target (91-95)	Low target (85-89)
< 84%	8.30%	14.05%
> 96%	21.45%	15.47%

Response to DSMC: Safety Issue of SpO2>95%

- **We believe that neither oximeter group in the SUPPORT trial is being exposed to excessive durations of SpO2 > 95% based on all currently available information and the actual SUPPORT Trial Data analyzed to date.**
- **Current analyses demonstrate that the highest duration of SpO2 > 95% was 28.13%, the lowest value that we believe has been reported for any group of preterm infants.**

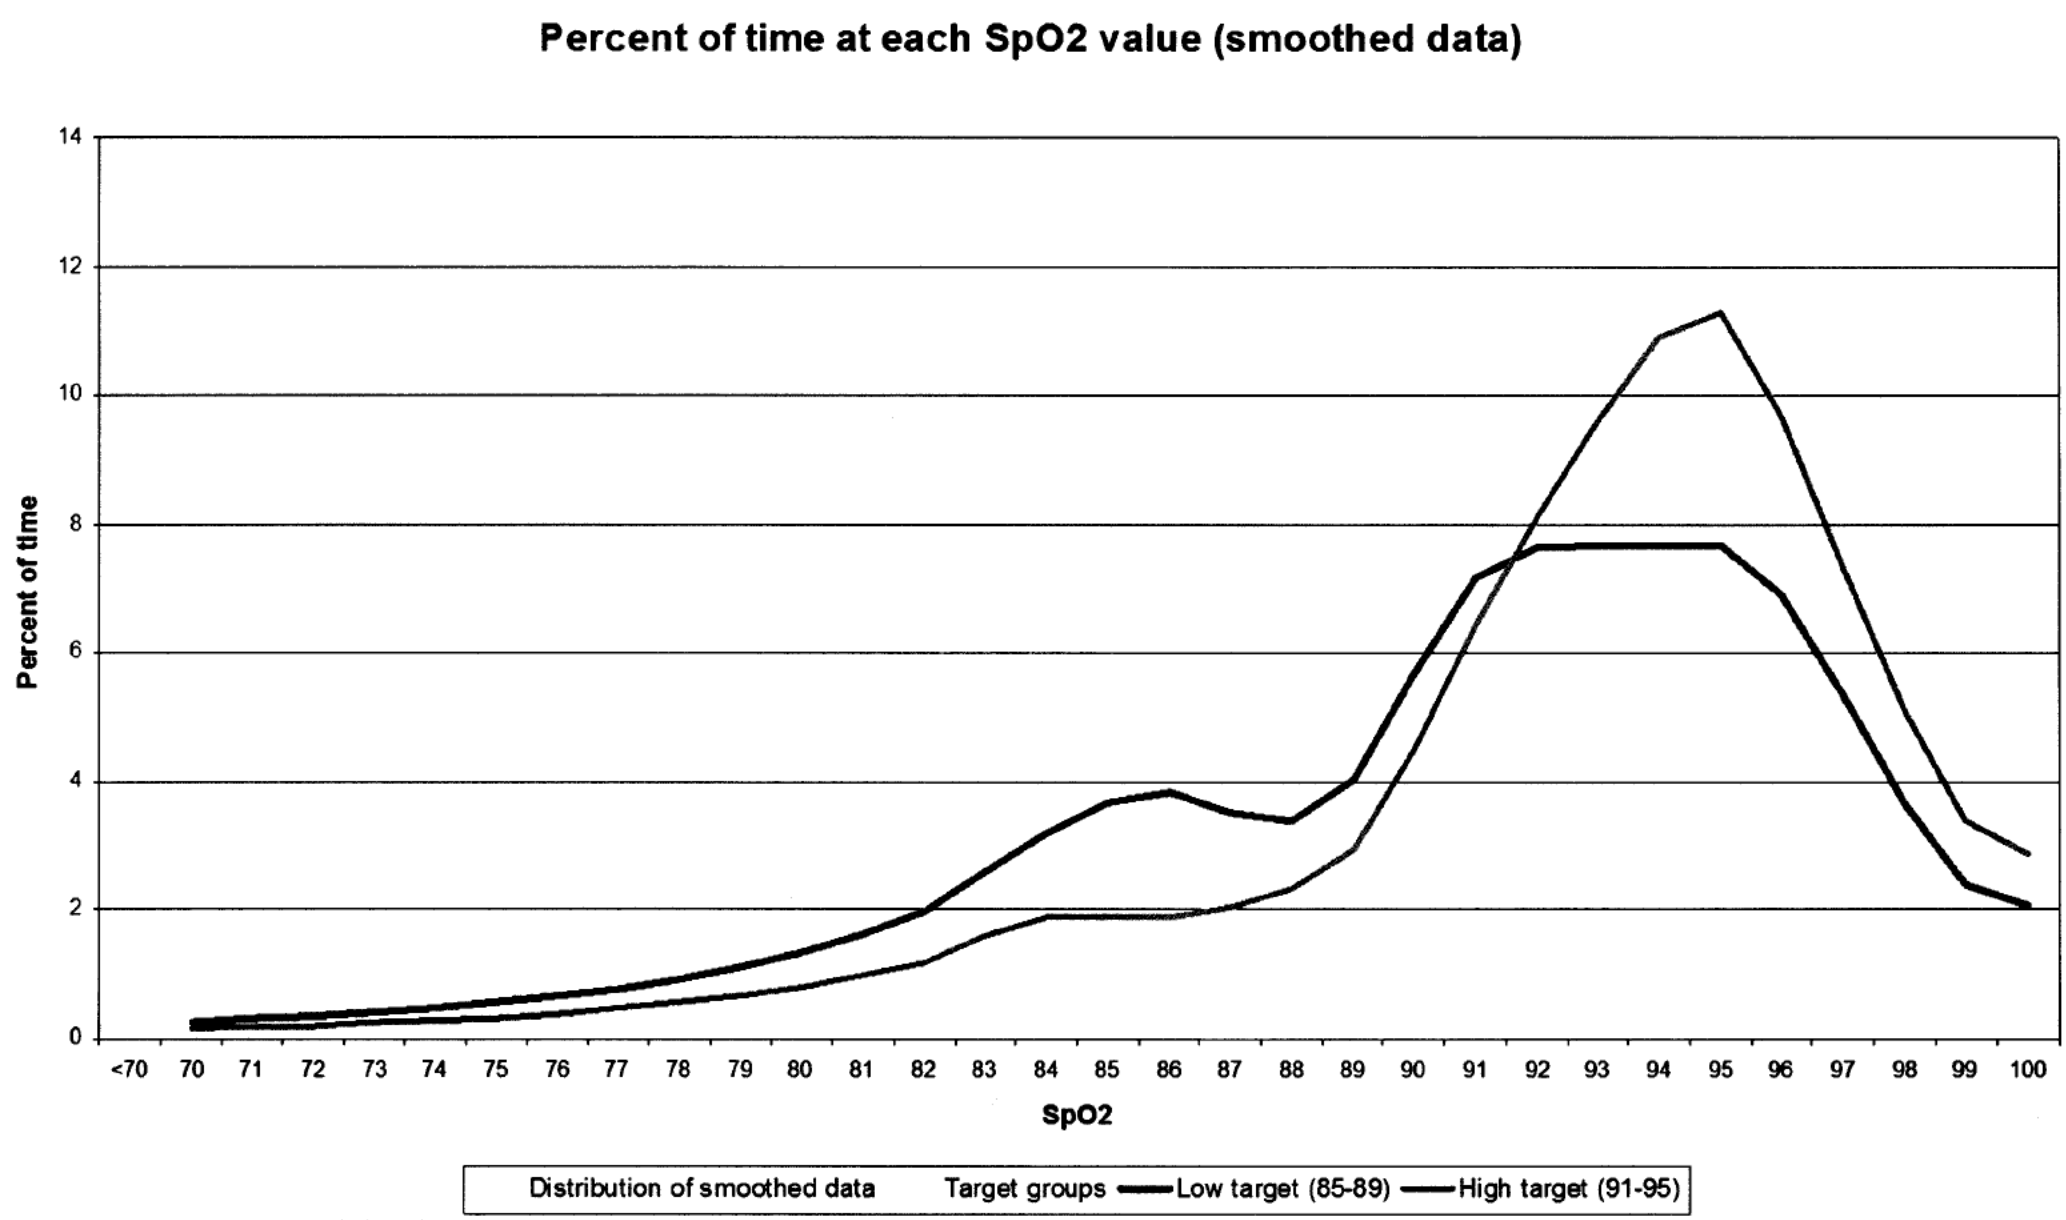
Response to DSMC:
Futility regarding Separation of Oximeter Groups

- **An evaluation of the oximeter group data has revealed that there is a difference in the mean - 90% vs 92% and median values for the 2 groups – 92% vs 94%**
- **In additional analyses have demonstrated that the cumulative time spent with an SpO2 of 90% or less is 24.0% (91% - 95%) versus 39.5% (85% - 89%) for a > 15% difference between the groups**

Response to DSMC:
Futility regarding Separation of Oximeter Groups

- **Further evaluation of the data analyzed in response to the concerns of the DSMC have shown the previously described differences for SpO2 values of < 84% and > 97% for the 2 oximeter groups**

Range Assigned	High target (91-95)	Low target (85-89)
< 84%	8.30%	14.05%
> 96%	21.45%	15.47%



Response to DSMC:
Futility regarding Separation of Oximeter Groups

- **It is uncertain what duration of differences will be associated with different short and long term outcomes, but we are achieving some separation to the present.**
- **We believe that greater separation is possible and have made a number of recommendations to ensure that this will occur**

Response to DSMC:

Suggestions for Increasing Separation of Oximeter Groups

1. **Require documentation that the oximeters alarm limits are set and functional as per protocol every 4-6 hours**
2. **Change our data collection for FiO2 to ensure that subsequent interval reports more accurately reflect saturations measured while on oxygen therapy and exclude saturations of infants in room air**

Response to DSMC:

Suggestions for Increasing Separation of Oximeter Groups

3. Further training and in-service at all the sites to stress the importance of keeping the SpO2 alarms functional and at the limits of 85% and 95%.
4. Develop guidelines for managing desaturations such that the increase in oxygen is proportional to the desaturation
5. Place bedside cards to indicate the desired target range

Response to DSMC:

Suggestions for Increasing Separation of Oximeter Groups

6. **Initiate compliance monitoring visits coordinated by RTI to visit random sites**
7. **Reanalyze group differences after an additional 100-150 infants have been enrolled.**

In response to the comments and concerns of the DSMC, the SUPPORT committee held a conference call Monday Nov 28th at 10:00 to 1130AM to prepare a response. This issue and the preparation of a response was then discussed by the entire NICHD Neonatal Research Network Steering Committee in a conference call held Wednesday. Nov 30th at 9:30 – 11:00 AM. This response has been reviewed by the SUPPORT Subcommittee, and subsequently by the Steering Committee, and reflects the input of all NICHD Principal Investigators.

- The DSMC made the following 2 comments in their letter regarding the SUPPORT trial. This was generated after they reviewed the oximeter data, which was corrected back to actual SpO2 values from the altered values displayed at the bedside:

1. There is a significant safety and exposure issue for the infants in the high saturation treatment group because an unacceptably high proportion of time was spent by these study subjects in the >95% range

2. There is a futility concern for this arm of the trial in that there does not appear to be substantial separation between the two high and low saturation treatment groups, and the babies are not being kept in the target range the appropriate amount of time in order to meaningfully test the oxygen saturation intervention as originally designed.

Based on these two issues, the consensus of the Committee was to recommend stopping the oxygen saturation arms of the SUPPORT trial due to safety and futility concerns.

We have responded to each of these concerns and our responses are detailed below

Response to Issue Number 1

We appreciate the concern expressed by the DSMC regarding a potential safety issue secondary to durations of SpO2 values greater than 95%.

1. Review of existing evidence and practice regarding durations of higher SpO2 values:

To date there are no prospective data which define the SpO2s experienced by the ELBW infant from birth as part of usual clinical care. Because no published studies have evaluated the effects of different target SpO2 ranges from birth on important outcomes, this was one of the principle reasons for the design and conduct of the SUPPORT trial.

A number of studies have evaluated different alarm limits, but have not reported the actual durations of SpO2 in the various ranges. Nghiem et al in a PAS abstract this year reported that nurses caring for ELBW infants believe that an acceptable oxygen saturation range should include higher upper limits than

specified by current policy (Nghiem et al, Nursing Opinions and Practices of Oxygenation in Prematures: The NOPOP Study PAS #3415, 2005). The study by Hagadorn reported as a late breaker at the PAS last year (Hagadorn et al, Actual vs Intended Pulse Oxygen Saturation (SpO2) in Infants <28 Weeks Gestation. PAS 2004, Attached) did report on the experience of monitoring the actual SpO2 for 72 hours in the first 4 weeks of life in 78 ELBW infants. They reported that the "lower limits of intended ranges at study centers varied between 83-92%, upper limits 92-98%. Infants were monitored for a median of 70 hours (25th-75th percentiles 67-71 hr) during each of the first 24 weeks. Overall median SpO2 for infants on supplemental O2 during the first 4 weeks was 95% (25th-75th percentiles 91-97%; range of study center medians 91-96%. Centers ranged between 16-71% compliance with their individual intended SpO2 range. Most noncompliance was above intended range." In comparing the SUPPORT data evaluated to date by the DSMC, it is of interest that the mean SpO2 in the 2 Oximeter arms is 90% and 92%, with medians of 92% and 94%, all of which are below that reported by Hagadorn et al (median=95).

The 2 other relevant trials, STOP-ROP and BOOST, both enrolled infants of > 32 weeks postmenstrual age (PMA), and maintained 2 levels of SpO2, 89% to 94% and 91-94% versus 95% to 98% and 96% to 99%, by administration of oxygen. These studies achieved reasonable separation, but did demonstrate substantial overlap of the intended ranges (estimated to be 50% or greater, D Phelps, PI for STOP-ROP). It is important to note that these studies were testing two ranges both of which were higher than the lower range of the SUPPORT trial (85% to 89%) and were treating infants who, for the most part, had recovered from their acute disease. In the BOOST trial 70% of the enrolled infants were < 28 weeks of age at birth (all of SUPPORT is < 28 weeks), 32 weeks PMA, and required oxygen at enrollment (Askie et al, New England Journal of Medicine. 2003; 349(10):959-967). The STOP-ROP trial enrolled infants with pre-threshold ROP at a PMA of 35.4 + 2.5 weeks of age (Phelps et al, Pediatrics. 2000; 105(2):295-310). These trials then gave the higher SpO2 range infants additional oxygen to increase their SpO2 to the desired range. STOP-ROP reported that the infants in the high range had an SpO2 > 95% for > 97% of the monitored time. These studies found an overall increase in pulmonary morbidity in the higher SpO2 range infants.

Examination of oximeter data from one of the NRN sites (Case Western, Walsh et al) obtained for an ongoing study evaluating infants similar to those enrolled in SUPPORT, and managed with conventional oximeters, revealed that for the 9 infants for whom results were available that the percentage of time with and SpO2 > 95% was > 50%.

2. Impact of SUPPORT oximeters algorithm on sat values:

The oximetry algorithm that was designed for the SUPPORT trial is such that re-conversion of the altered oximeter values does not result in a discrete SpO2 number for every displayed value. SpO2 values, of 93%, 94% 95% and 96% will all be reconverted to a single value. As an example, when the actual percent of time at each individual SpO2 point was calculated for this review, in

the 91% to 95% group, there was 5.76% of the time spent at an actual SpO2 of 96% and 8.38% of the time spent at values that represented conversion from readings of 93% to 95%. In the 85% to 89% arm, values of 84%, 85%, 86% and 87% will be reconverted to a single value of 84%. This is a result of having the displayed values return to non-skewed SpO2 values at < 84% and > 96%, a safety design felt to be important by all involved in this trial (See Attached file USCD1). Thus the percentages reported to the DSMC for some of the ranges that include these values were not an accurate representation of the true values. However all values > 96% and < 84% are actual and do not require any conversion.

Percent of time of spent at SpO2 < 84% and > 96%
(RTI, Dec 2, 2005)

Range **Assigned**	High target (91-95)	Low target (85-89)
< 84%	8.30	14.05
> 96%	21.45	15.47

In the current SUPPORT study, an initial analyses utilizing only unaltered SpO2 values as shown above , ie those below 84% and above 96%, have shown that one arm had an SpO2 > 96% for 15.47% versus 21.45% of the time for the comparison arm, and the duration of an SpO2 < 84% was also different at 14.05% versus 8.30%. The values for SpO2s > 96% using unaltered data suggests that the SUPPORT trial to date has, if anything, reduced the duration of higher oxygen saturations.

In addition, analyses using only actual SpO2 demonstrate that the infants in this trial who are receiving supplemental oxygen are spending approximately 70% of the time with a true SpO2 value between 84% and 96%. We believe that this is information is very encouraging.

3. Impact of inclusion of data from periods in room air on saturation distributions:

As part of the SUPPORT trial, we collect information about inhaled oxygen concentration 3 times a day for the first 14 days and daily thereafter. We believe that an improved documentation of the times when infants are on room air will allow us to determine the saturations during actual oxygen exposure. At the present an infant is considered to be receiving supplemental oxygen if he/she requires oxygen for greater than 2 hours. This results in infants being categorized as receiving supplemental oxygen for significant periods when they are actually in room air. This would result in durations of SpO2 greater than 95% that were felt to be modifiable and reported as such when in fact there is no effective treatment for such elevated SpO2s. In addition, we do not know if such SpO2s on room air are associated with any morbidity. From the SUPPORT study data analyses to date we know that infants in room air have SpO2s > 95% for 46% to 69% of the time. By using only information for actual SpO2 values of

96%, we have determined that the infants in the 91%-95% group had a duration at an SpO2 of 96% of 6.68%, and a total duration of 96% or greater of 28.13%.

In view of this design, we would suggest that all future interval analyses for safety examine the ranges of <84% and >96% and consider those ranges for review of low and high durations of SpO2..

We believe that the SUPPORT trial will actually define the periods of time that ELBW infants spend with different ranges of SpO2, and that it is essential to collect this information. In addition, as our findings indicate a lower true percent of the time at SpO2 values >95%, and lower median SpO2 values than has previously been reported, we are in fact, reducing the time with high SpO2 values compared to usual care. The SUPPORT trial carefully evaluates risks, and we will be evaluating group differences for all important short and long term outcomes.

The SUPPORT trial methodology actively encourages all caretakers to keep SpO2 < 96% by having alarm limits set at 85% and 95%. These limits were utilized because it was felt that these represented current practice. The oximetry algorithms were designed to keep infants in the narrower target range of 88% to 92% with the realization that setting alarm limits at these values would severely increase the frequency of the alarms sounding. Nevertheless, our results to date suggest that we have decreased the expected percent of time > 95%, and in one group the value of 14% may be as low as is achievable in an actual clinical environment given the evidence provided by Hagadorn et al and Nghiem et al.

We believe the SUPPORT study will define the distribution and durations of pulse oximetry values among premature infants in highly staffed, dedicated academic centers, and among infants randomized to two different target ranges. For this reason alone, the SUPPORT trial will be very valuable. All of the procedures outlined below in response to your second concern will also allow us to further increase the percentage of time that the infants are in the maximally altered SpO2 ranges which we believe will further increase separation of these groups.

Response to Issue Number 2

There is concern that we have not achieved adequate separation by the current oximeters and study personnel.

1. As described above, the results of additional analyses performed in response to the concerns of the DSMC show differences in the durations of low and high SpO2s between the 2 oximeter groups. A careful analysis of the most recent converted values demonstrates that the cumulative time spent with an SpO2 of 90% or less is 24.0% (91% - 95%) versus 39.5% (85% - 89%), for the 2 oximeter groups, supporting the ability of the altered oximeters to produce differential SpO2 exposures.

2. We do acknowledge that it would be desirable to increase the percentage of time in the narrower target range and towards this end would propose the following changes to SUPPORT:

A. We will require **documentation that the oximeters alarm limits are set and functional as per protocol every 4-6 hours**. We have found that in some units the high alarms are being turned off, and thus believe that such documentation will greatly assist in decreasing the actual time that the SpO2 is > 96%. This task will be assigned to the most appropriate personnel in each unit, which may include bedside or research nurses or respiratory therapists, and this procedure is already being done in many NRN units.

B. We will immediately initiate a **change in our data collection for FiO2 to ensure that subsequent interval reports more accurately reflect saturations measured while on oxygen therapy and exclude saturations of infants in room air.** We will change the data form to indicate that the infant was either in oxygen for the entire 24 hours, and if not, will provide a more accurate estimate of the true time in oxygen, and we will continue with this form of data collection for the entire time that the infant is receiving oxygen. In the current protocol we collect such information 3 times a day for the first 14 days only and then daily thereafter. We believe that more frequent and extended documentation will allow us to determine more accurately the actual time that an infant is in room air. At the present the infant is considered to have spent a day in oxygen if he/she requires oxygen for greater than 2 hours. This results in infants being categorized in oxygen for significant periods when they are in room air. While in room air, we cannot manipulate the SpO2, and thus knowledge of the true time in oxygen will produce a more accurate representation of oximetry results that are subject to care interventions.

C. We will initiate **further training and in-service at all the sites to stress the importance of keeping the SpO2 alarms functional and at the limits of 85% and 95%**. In the past these were guidelines, and we will now change the study manual and protocol to indicate these limits are now set by protocol and that violations will be documented. We will encourage all caretakers to aim for an SpO2 value of 90% and make every effort to educate caretakers to make smaller adjustments in FiO2 and ensure that the infant is maintained between the 87% to 93%, the range with the maximal separation of the study oximeters. We will further facilitate the use of the 2 hour and 12 hour histograms showing the infants' actual ranges to provide feedback to the caretakers regarding the percentage of time in the target ranges.

D. We will develop **guidelines for managing desaturations such that the increase in oxygen is proportional to the desaturation**. More modulated increases in oxygen during these desaturation events will minimize overshoot and the potential of high SpO2 values. We would hope that such changes – ie increasing the FiO2 in steps of 5% as opposed to much larger increases will

decrease the resultant overshoots creating the high SpO2 values. This will be included in the revised manual of operations.

E. We will place bedside cards to indicate the desired target range.

F. We will **initiate compliance monitoring visits coordinated by RTI to visit random sites**. These visits had been planned, but had not yet been initiated. The teams will consist of a member of RTI and a study coordinator, and they will review the adherence to the protocol and any other relevant issues.

G. We would recommend that at a minimum, **the unblinded oximetry data be reviewed again after an additional 100 to 150 infants have been enrolled in this trial.**

We thank the DSMC for their thoughtful concerns. We trust that our plans to move forward with the SUPPORT trial are acceptable to the DSMC. We are anxious to initiate the above changes, seek IRB approvals and re-activate this trial.

Hi Dale
Thanks for these suggestions.
You have provided us with some very good ideas. I will be talking with RTI to see how quickly such analyses could be performed. We have demonstrated from the analyses at present that there is some separation between the 2 oximeter groups, both by the difference in median SpO2, and the durations of SpO2 > 97% and < 84%. We need to get our response to the DSMC so that they can have a reasonable time to review these.
I will prepare some additional information based in FiO2 analyses using your approach, and be prepared to present these.
I think that we have dealt with the issues that have been raised, and I fear that if we don't have adequate FiO2 differences based on 150 infants, that this may be used to stop this arm.
Marie Gantz has provided some further data looking at the time at each SpO2 value with smoothed curves and histograms which I think are useful. I think that these address some of your thoughts re STOP-ROP
I have attached these for everyone to see.
Please pass on my thanks to the entire Rochester Group.
Be well
Neil

Subject: RE: More thoughts about are the groups separated

Neil,

Our group discussed the SUPPORT suspension and the rationale for it and the responses on Friday.

On the issue of "is there any real separation of the two groups", we had two additional thoughts.

1) Direct data: a frequency histogram of saturations (during modifiable time) can be prepared with 'accurate' saturations. When the numbers looked 'too similar' to the DSMC for STOP-ROP, (lack of separation), they found the histograms to be persuasive.

a. The 'real' saturations should be available since you have the 86.5, 85.75 etc. data from the downloads. It is a matter of time and computing to do it.

b. If you want to save time for RTI, you could limit the amount of time from one infant that is analyzed by limiting it to just the first 2 weeks... or first 4 weeks?

c. You won't be able to get the really clean modifiable data until the data forms are changed. (a hitch)

2) Indirect data: Since you have a lot of kids (153), and thereare data for the first 14 days on FiO2 at three points in time on each of those first 14 days, you should be able to look at the "area under the curve" for the oxygen exposure during the first 14 days.

If the saturation targets are really resulting in a difference in bedside practice, they should have an impact on the oxygen exposure that the two groups receive.
The group assigned to the lower saturation target should be in lower FiO2.

Analysis: use the 3 FiO2 points/day to generate mean oxygen exposure each day (1st 14 days).
Examples:
Room air for 24 hours would be 0.21 x 24 = 5.04 O2-hrs
100% oxygen for 24 hrs would be 1.00x24 = 24.00 O2-hr
30% at time 1, 50% at time 2 and 29% at time 3 (let's assume times were 7, 9 and 8 hrs apart for the example).
0.30x7 + 0.50x9 + 0.29x8 = 2.10 + 4.50 + 2.32 = 8.92 O2-hrs

Then average O2-hrs for day 1 across group 1 vs group 2
Repeat for days 2,3,4...through 14

Plot: O2-hrs vs day after birth in groups 1 and 2

If the targets are resulting in different PRACTICE, the curves should reveal different oxygen exposure.

It would be supportive, indirect evidence (and maybe seen only by DSMC?). If there is no difference, we have a problem.

Codicle: if the ventilatory arm of the 2x2 design also affects the FiO2 received, it may have to be examined in four groups instead of two.

Neil and all. I agree with Neil's idea to lower the sat low alarm limit to 83% in those hospitals that want to establish that policy but it would probably be better for it to be a hospital polivy rather than a trial driven effort.

Subject: RE: DSMC SUPPORT Conference Call

Good Day Rose

We discussed whether we should lower the limit to 80% and I understood that the response was to leave our alarms at the present level. I think that we should probably change the lower end to be in keeping with true SpO2 values - ie 83%. I would not increase the hi side as we only have 4 SpO2 points to play with, and we do not want the infants at 100% - we are currently at 99% and 100% for about 6.8% of the time in the 91-95 group, versus 4.8 in the 85 -89 group. I would suggest that we move the low alarm to 83# as this is the only value that is true for all oximeters. We will probably increase the time < 85% but if we increase the spread even further, that would be great. In addition we should think about the fact that our SpO2 medians differ by 2%. I think that this is evidence of the difference in SpO2 exposure between the groups -

High target (91-95)

Low target (85-89)

Median

94

92

The question is - what difference can we expect to achieve?

Our algorithm is only active maximally between 87% and 93%, and the fact that we return to normal works against us achieving a large spread. However, we are creating a difference in the entire SpO2 range.

I am of the belief that we will only be able to get to a 3% difference between the medians. More importantly how much difference to we want at the low and high ends - we currently have about 6% greater time below 84 in the 85-89 group, and about 7% less time > 97% for this group. Thus the low group is spending more time with lower actual sats

Range

High target (91-95)

Low target (85-89)

<84

8.30

14.05

>96

21.44

15.47

In a given 24 hour period, this group will therefore have (24X.07)=1.7 more hours each day with a SpO2 < 84%. Similarly the 91-95 group will have about the same duration with SpO2 values > 97% each day. I do not have any data which would indicate what differences we should aim for , and I am certain that with the numbers of data points that we have that these differences at the edges will be very significant (I would guess p<.00001). What difference is necessary to produce differential clinical outcomes? Do we already have enough difference?

As we further tighten up the time in the narrow range, I would anticipate that we will also increase these differences. Is there a difference or time time/day that we would consider too much at either end?

I would suggest that we have no such data, and that this study will determine these values.

However, I am anticipating the question of how much difference would be desirable? I would currently suggest that a target of 3% difference in the means may be a reasonable target, but I do not want to be held to that. We may discover that we already have enough difference when all the data are in for the study.

I would appreciate everyones' thoughts on these points as we prepare for the DSMC meeting.

Thanks for considering these issues.

Be well

Neil

Neil

Are we going to bring up a low saturation alarm limit of 80?? I am fine with what is written, but this had been discussed to avoid overshoot when oxygen gets turned up.

Thanks for all the hard work and effort.

Hi Rose

Here is the reworked reply and letter with everyone's suggestions included. I have attached all the relevant files. You may want to send them Marie's last hourly analyses which we quote. Your call as to whether they would appreciate this or not.

Thanks for your help

Are you swimming yet??

Yes, I believe Neil sent them. I'll plan to send them the following:

Agenda and list of participants

List of members with their specialty, etc.

SUPPORT Protocol

Letter of Response from the Steering Committee

The two abstracts.

Anything else?

Hi Rose
The most recent data the differences between the groups persist, but is somewhat less with more numbers as suspected. This is a better representation of the study to date. – I have added these to the latest DMC response attached.
Rose, please use this version. We probably would want to send this file to the DSMC (Percent of time 12-2-05)
As always, your call
Be well
Neil

Subject: New data

Hi Neil,

Attached is another pulse ox data update. This one is based on 166 out of a total of 173 infants, so it should be very representative of what our data look like as a whole. I will send you a revision based on all of the infants on Monday.

Notice that, in addition to the graph showing the percent of time spent at each converted (actual) SpO2 value, there are two additional graphs. One is a bar graph in which the numbers have been redistributed to achieve a smoothed effect. There is a table in the document explaining how the smoothing was done. The third and final graph shows the distribution for each treatment group which has been smoothed a little bit more.

Have a good weekend.

Marie

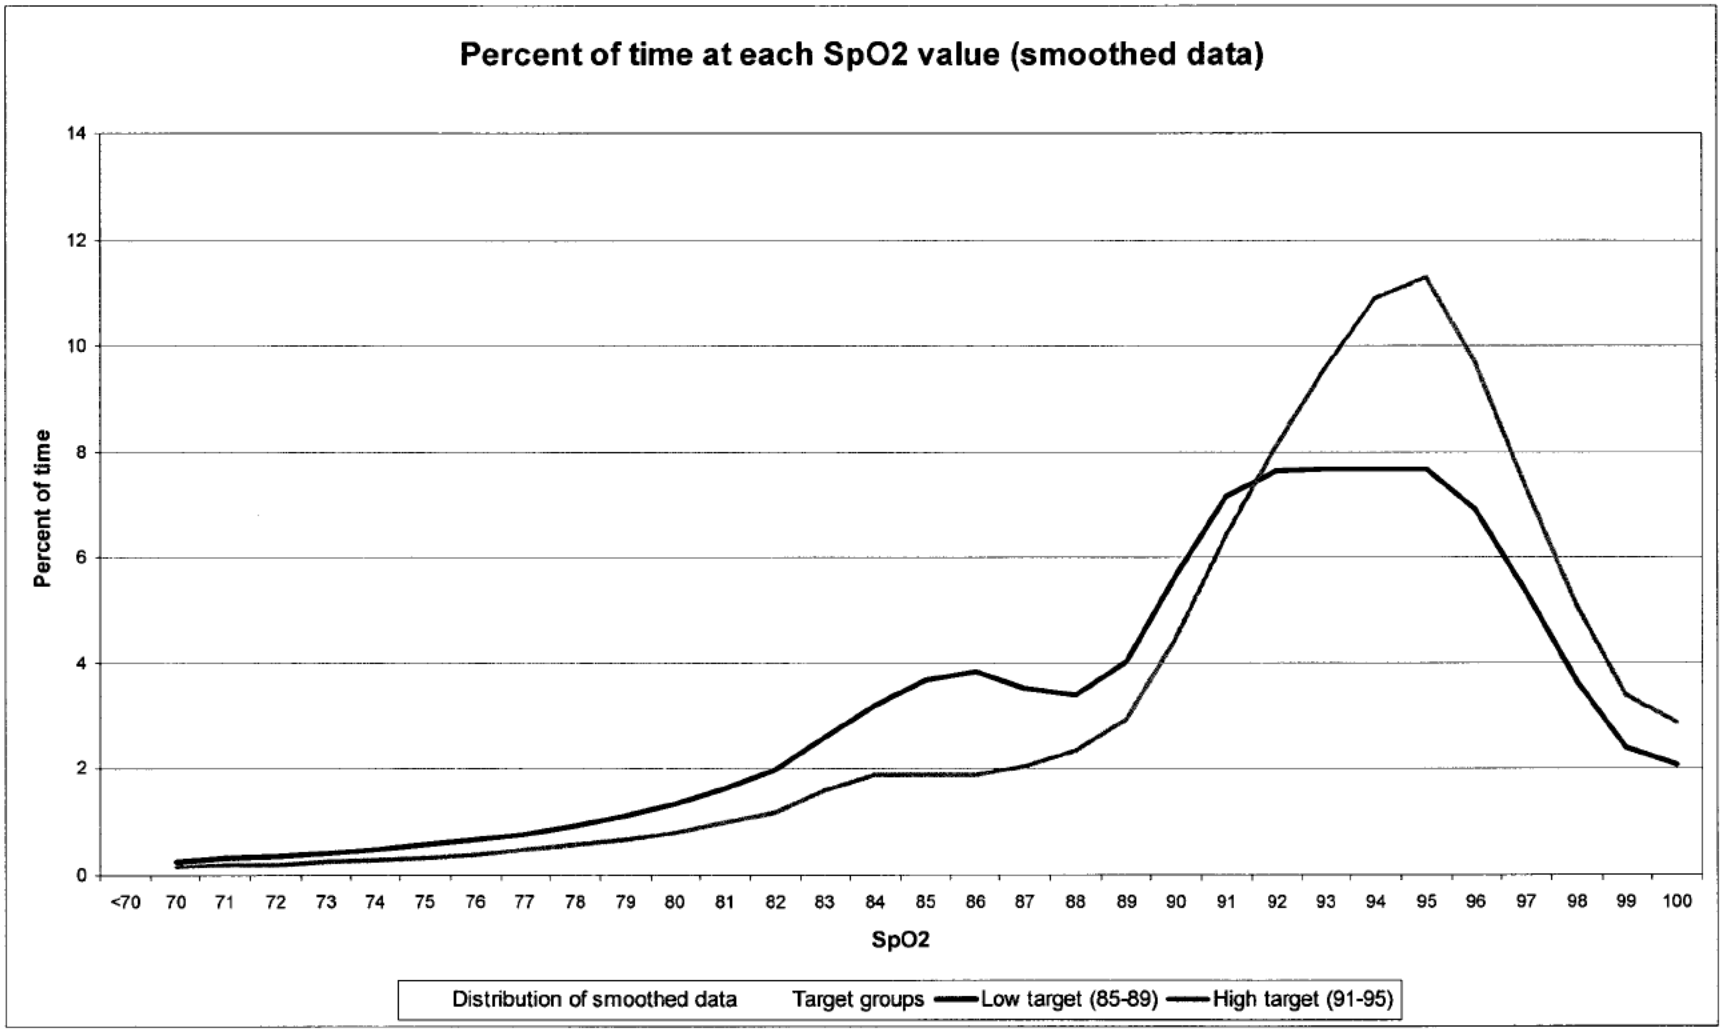
Percent of time at 85 includes converted values of 85, 84.75 and half the percent of time at 84.5	Burgundy checked



In response to the comments and concerns of the DSMC, the SUPPORT committee held a conference call Monday Nov 28th at 10:00 to 1130AM to prepare a response. This issue and the preparation of a response was then discussed by the entire NICHD Neonatal Research Network Steering Committee in a conference call held Wednesday. Nov 30th at 9:30 – 11:00 AM. This response has been reviewed by the SUPPORT Subcommittee, and subsequently by the Steering Committee, and reflects the input of all NICHD Principal Investigators.

- The DSMC made the following 2 comments in their letter regarding the SUPPORT trial. This was generated after they reviewed the oximeter data, which was corrected back to actual SpO2 values from the altered values displayed at the bedside:

1. There is a significant safety and exposure issue for the infants in the high saturation treatment group because an unacceptably high proportion of time was spent by these study subjects in the >95% range

2. There is a futility concern for this arm of the trial in that there does not appear to be substantial separation between the two high and low saturation treatment groups, and the babies are not being kept in the target range the appropriate amount of time in order to meaningfully test the oxygen saturation intervention as originally designed.

Based on these two issues, the consensus of the Committee was to recommend stopping the oxygen saturation arms of the SUPPORT trial due to safety and futility concerns.

We have responded to each of these concerns and our responses are detailed below

Response to Issue Number 1

We appreciate the concern expressed by the DSMC regarding a potential safety issue secondary to durations of SpO2 values greater than 95%.

1. Review of existing evidence and practice regarding durations of higher SpO2 values:

To date there are no prospective data which define the SpO2s experienced by the ELBW infant from birth as part of usual clinical care. Because no published studies have evaluated the effects of different target SpO2 ranges from birth on important outcomes, this was one of the principle reasons for the design and conduct of the SUPPORT trial.

A number of studies have evaluated different alarm limits, but have not reported the actual durations of SpO2 in the various ranges. Nghiem et al in a PAS abstract this year reported that nurses caring for ELBW infants believe that an acceptable oxygen saturation range should include higher upper limits than

specified by current policy (Nghiem et al, Nursing Opinions and Practices of Oxygenation in Prematures: The NOPOP Study PAS #3415, 2005). The study by Hagadorn reported as a late breaker at the PAS last year (Hagadorn et al, Actual vs Intended Pulse Oxygen Saturation (SpO2) in Infants <28 Weeks Gestation. PAS 2004, Attached) did report on the experience of monitoring the actual SpO2 for 72 hours in the first 4 weeks of life in 78 ELBW infants. They reported that the "lower limits of intended ranges at study centers varied between 83-92%, upper limits 92-98%. Infants were monitored for a median of 70 hours (25th-75th percentiles 67-71 hr) during each of the first 24 weeks. Overall median SpO2 for infants on supplemental O2 during the first 4 weeks was 95% (25th-75th percentiles 91-97%; range of study center medians 91-96%. Centers ranged between 16-71% compliance with their individual intended SpO2 range. Most noncompliance was above intended range." In comparing the SUPPORT data evaluated to date by the DSMC, it is of interest that the mean SpO2 in the 2 Oximeter arms is 90% and 92%, with medians of 92% and 94%, all of which are below that reported by Hagadorn et al (median=95).

The 2 other relevant trials, STOP-ROP and BOOST, both enrolled infants of > 32 weeks postmenstrual age (PMA), and maintained 2 levels of SpO2, 89% to 94% and 91-94% versus 95% to 98% and 96% to 99%, by administration of oxygen. These studies achieved reasonable separation, but did demonstrate substantial overlap of the intended ranges (estimated to be 50% or greater, D Phelps, PI for STOP-ROP). It is important to note that these studies were testing two ranges both of which were higher than the lower range of the SUPPORT trial (85% to 89%) and were treating infants who, for the most part, had recovered from their acute disease. In the BOOST trial 70% of the enrolled infants were < 28 weeks of age at birth (all of SUPPORT is < 28 weeks), 32 weeks PMA, and required oxygen at enrollment (Askie et al, New England Journal of Medicine. 2003; 349(10):959-967). The STOP-ROP trial enrolled infants with pre-threshold ROP at a PMA of 35.4 + 2.5 weeks of age (Phelps et al, Pediatrics. 2000; 105(2):295-310). These trials then gave the higher SpO2 range infants additional oxygen to increase their SpO2 to the desired range. STOP-ROP reported that the infants in the high range had an SpO2 > 95% for > 97% of the monitored time. These studies found an overall increase in pulmonary morbidity in the higher SpO2 range infants.

Examination of oximeter data from one of the NRN sites (Case Western, Walsh et al) obtained for an ongoing study evaluating infants similar to those enrolled in SUPPORT, and managed with conventional oximeters, revealed that for the 9 infants for whom results were available that the percentage of time with and SpO2 > 95% was > 50%.

2. Impact of SUPPORT oximeters algorithm on sat values:

The oximetry algorithm that was designed for the SUPPORT trial is such that re-conversion of the altered oximeter values does not result in a discrete SpO2 number for every displayed value. SpO2 values, of 93%, 94% 95% and 96% will all be reconverted to a single value. As an example, when the actual percent of time at each individual SpO2 point was calculated for this review, in

the 91% to 95% group, there was 5.76% of the time spent at an actual SpO2 of 96% and 8.38% of the time spent at values that represented conversion from readings of 93% to 95%. In the 85% to 89% arm, values of 84%, 85%, 86% and 87% will be reconverted to a single value of 84%. This is a result of having the displayed values return to non-skewed SpO2 values at < 84% and > 96%, a safety design felt to be important by all involved in this trial (See Attached file USCD1). Thus the percentages reported to the DSMC for some of the ranges that include these values were not an accurate representation of the true values. However all values > 96% and < 84% are actual and do not require any conversion.

Percent of time of spent at SpO2 < 84% and > 96%
(RTI, Dec 2, 2005)

Range **Assigned**	High target (91-95)	Low target (85-89)
< 84%	8.30	14.05
> 96%	21.45	15.47

In the current SUPPORT study, an initial analyses utilizing only unaltered SpO2 values as shown above , ie those below 84% and above 96%, have shown that one arm had an SpO2 > 96% for 15.47% versus 21.45% of the time for the comparison arm, and the duration of an SpO2 < 84% was also different at 14.05% versus 8.30%. The values for SpO2s > 96% using unaltered data suggests that the SUPPORT trial to date has, if anything, reduced the duration of higher oxygen saturations.

In addition, analyses using only actual SpO2 demonstrate that the infants in this trial who are receiving supplemental oxygen are spending approximately 70% of the time with a true SpO2 value between 84% and 96%. We believe that this is information is very encouraging.

3. Impact of inclusion of data from periods in room air on saturation distributions:

As part of the SUPPORT trial, we collect information about inhaled oxygen concentration 3 times a day for the first 14 days and daily thereafter. We believe that an improved documentation of the times when infants are on room air will allow us to determine the saturations during actual oxygen exposure. At the present an infant is considered to be receiving supplemental oxygen if he/she requires oxygen for greater than 2 hours. This results in infants being categorized as receiving supplemental oxygen for significant periods when they are actually in room air. This would result in durations of SpO2 greater than 95% that were felt to be modifiable and reported as such when in fact there is no effective treatment for such elevated SpO2s. In addition, we do not know if such SpO2s on room air are associated with any morbidity. From the SUPPORT study data analyses to date we know that infants in room air have SpO2s > 95% for 46% to 69% of the time.

In view of this design, we would suggest that all future interval analyses for safety examine the ranges of <84% and >96% as those ranges that are considered to be low and high.

We believe that the SUPPORT trial will actually define the periods of time that ELBW infants spend with different ranges of SpO2, and that it is essential to collect this information. In addition, as our findings indicate a lower true percent of the time at SpO2 values >95%, and lower median SpO2 values than has previously been reported, we are in fact, reducing the time with high SpO2 values compared to usual care. The SUPPORT trial carefully evaluates risks, and we will be evaluating group differences for all important short and long term outcomes.

The SUPPORT trial methodology actively encourages all caretakers to keep SpO2 < 96% by having alarm limits set at 85% and 95%. These limits were utilized because it was felt that these represented current practice. The oximetry algorithms were designed to keep infants in the narrower target range of 88% to 92% with the realization that setting alarm limits at these values would severely increase the frequency of the alarms sounding. Nevertheless, our results to date suggest that we have decreased the expected percent of time > 95%, and in one group the value of 14% may be as low as is achievable in an actual clinical environment given the evidence provided by Hagadorn et al and Nghiem et al.

We believe the SUPPORT study will define the distribution and durations of pulse oximetry values among premature infants in highly staffed, dedicated academic centers, and among infants randomized to two different target ranges. For this reason alone, the SUPPORT trial will be very valuable. All of the procedures outlined below in response to your second concern will also allow us to further increase the percentage of time that the infants are in the maximally altered SpO2 ranges which we believe will further increase separation of these groups.

Response to Issue Number 2

There is concern that we have not achieved adequate separation by the current oximeters and study personnel.

1. As described above, the results of additional analyses performed in response to the concerns of the DSMC show differences in the durations of low and high SpO2s between the 2 oximeter groups. A careful analysis of the most recent converted values demonstrates that the cumulative time spent with an SpO2 of 90% or less is 24.0% (91% - 95%) versus 39.5% (85% - 89%), for the 2 oximeter groups, supporting the ability of the altered oximeters to produce differential SpO2 exposures.

2. We do acknowledge that it would be desirable to increase the percentage of time in the narrower target range and towards this end would propose the following changes to SUPPORT:

A. We will require **documentation that the alarm limits are set and functional as per protocol every 4-6 hours**. We have found that in some units the high alarms are being turned off, and thus believe that such documentation will greatly assist in decreasing the actual time that the SpO2 is > 96%. This task will be assigned to the most appropriate personnel in each unit, which may include bedside or research nurses or respiratory therapists, and this procedure is already being done in many NRN units.

B. We will immediately initiate a **change in our data collection for FiO2 to ensure that subsequent interval reports more accurately reflect saturations measured while on oxygen therapy and exclude saturations of infants in room air.** We will change the data form to indicate that the infant was either in oxygen for the entire 24 hours, and if not, will provide a more accurate estimate of the true time in oxygen, and we will continue with this form of data collection for the entire time that the infant is receiving oxygen. In the current protocol we collect such information 3 times a day for the first 14 days only and then daily thereafter. We believe that more frequent and extended documentation will allow us to determine more accurately the actual time that an infant is in room air. At the present the infant is considered to have spent a day in oxygen if he/she requires oxygen for greater than 2 hours. This results in infants being categorized in oxygen for significant periods when they are in room air. While in room air, we cannot manipulate the SpO2, and thus knowledge of the true time in oxygen will produce a more accurate representation of oximetry results that are subject to care interventions.

C. We will initiate **further training and in-service at all the sites to stress the importance of keeping the SpO2 alarms functional and at the limits of 85% and 95%**. In the past these were guidelines, and we will now change the study manual and protocol to indicate these limits are now set by protocol and that violations will be documented. We will encourage all caretakers to aim for an SpO2 value of 90% and make every effort to educate caretakers to make smaller adjustments in FiO2 and ensure that the infant is maintained between the 87% to 93%, the range with the maximal separation of the study oximeters. We will further facilitate the use of the 2 hour and 12 hour histograms showing the infants' actual ranges to provide feedback to the caretakers regarding the percentage of time in the target ranges.

D. We will develop **guidelines for managing desaturations such that the increase in oxygen is proportional to the desaturation**. More modulated increases in oxygen during these desaturation events will minimize overshoot and the potential of high SpO2 values. We would hope that such changes – ie increasing the FiO2 in steps of 5% as opposed to much larger increases will decrease the resultant overshoots creating the high SpO2 values. This will be included in the revised manual of operations.

E. **We will place bedside cards to indicate the target range**.

F. We will **initiate compliance monitoring visits coordinated by RTI to visit random sites**. These visits had been planned, but had not yet been initiated. The teams will consist of a member of RTI and a study coordinator, and they will review the adherence to the protocol and any other relevant issues.

G. We would recommend that at a minimum, the unblinded oximetry data be reviewed again after an additional 100 to 150 infants have been enrolled in this trial.

We thank the DSMC for their thoughtful concerns. We trust that our plans to move forward with the SUPPORT trial are acceptable to the DSMC. We are anxious to initiate the above changes, seek IRB approvals and re-activate this trial.

Hi Jon
I agree with concerns that we do not collect excessive data. Our current thought is that we indicate whether a child was on oxygen for an entire day of not. If not, we then ask the coordinator to review that day and assign the infants to either room air or oxygen based on which mode was the more prevalent during the day – that will be better than current but not result in excessive data. We also agree that we need site visits, and will include this monitoring as one the of the purposes of that visit.
Thanks for your comments

Jon:

In answer to your question for me, in our reported analyses we have only included days on which we know the infant received supplemental oxygen. Thus, if the SUPP05 and SUPP11 have not been submitted for the infant, he or she is not included.

Regarding your suggestion about FiO2 data collection, as Neil knows, I am all for limited data collection, and would support whatever reasonable approach that can achieve it! (Our data processing resources are stretched as is with the volume of pulse ox data that we are having to deal with!) But, I thought that the purpose of collecting more FiO2 data was to allow us to identify when the infants were on supplemental oxygen during the course of the day. If this is the case, then the random audit approach may not be very useful, though I definitely hear your point about the accuracy and credibility of any data we collect on this score.

Thanks

Abhik

> Neil, I was out of town and unable to be on the conference call. It seems to me that the proposal is to spend an enormous amount of time to collect data that still may not be very interpretable. Even if we had saturation and FiO2 for every baby for every hour as taken off the nursing flow sheets, it would be a big stretch to believe that these were necessarily accurate or that FiO2 and oxygen saturation were recorded at the same time (or even with several minutes of each other). If there is to be greater scrutiny of the flow sheets and nursing compliance using the flow sheet, it may well be that nurses—like other people---would be less likely to values that would prompt criticism. It is quite plausible that they would instead wait to a later moment to record data at a time when the values would be considered to be appropriate.

Would you consider instead a random audit in which the respiratory therapists (at any time) and/or research nurses (during the day) would at randomly selected times and babies (which could be selected by RTI), walk up to the bedside and record the FiO2 and saturation at that moment. With 16 centers, it wouldn't take very many observations to get a reasonably precise estimate of the proportion of time that the FiO2 was inappropriate. This could be done on a continuous basis or intermittently as desired and would require much less data recording, analytic effort, and total cost and be much more likely to be accurate and unbiased. It would also give information about inappropriately low FiO2.

Abhik

Georgia and I want to be sure that the saturation analyses were really limited to those infants for whom the clinical data had been submitted that would allow the analyst to have some chance to relate the saturation data to whether the infants were receiving oxygen for part of the day. In our site, oximeter download had been submitted for approximately 14 infants before 11/7. However, supp 05 and supp 11 (both needed to assess FiO2 at the ages when the oximeter downloads were obtained) had been submitted for only 7 infants) Can you sort your data quickly and determine whether there were others infants included in the analysis of oxygen saturation? If so, then there may be other babies who were inadvertently included in the analysis from other centers.

Subject: RE: DSMC SUPPORT Conference Call

Do you know when the letter will be ready to send out to the DSMC?

In response to the comments and concerns of the DSMC, the SUPPORT committee held a conference call Monday Nov 28th at 10:00 to 1130AM to prepare a response. This issue and the preparation of a response was then discussed by the entire NICHD Neonatal Research Network Steering Committee in a conference call held Wednesday. Nov 30th at 9:30 – 11:00 AM. This response has been reviewed by the SUPPORT Subcommittee, and subsequently by the Steering Committee, and reflects the input of all NICHD Principal Investigators.

- The DSMC made the following 2 comments in their letter regarding the SUPPORT trial. This was generated after they reviewed the oximeter data, which was corrected back to actual SpO2 values from the altered values displayed at the bedside:

1. There is a significant safety and exposure issue for the infants in the high saturation treatment group because an unacceptably high proportion of time was spent by these study subjects in the >95% range

2. There is a futility concern for this arm of the trial in that there does not appear to be substantial separation between the two high and low saturation treatment groups, and the babies are not being kept in the target range the appropriate amount of time in order to meaningfully test the oxygen saturation intervention as originally designed.

Based on these two issues, the consensus of the Committee was to recommend stopping the oxygen saturation arms of the SUPPORT trial due to safety and futility concerns.

We have responded to each of these concerns and our responses are detailed below

Response to Issue Number 1

We appreciate the concern expressed by the DSMC regarding a potential safety issue secondary to durations of SpO2 values greater than 95%.

1. Review of existing evidence and practice regarding durations of higher SpO2 values:

To date there are no prospective data which define the SpO2s experienced by the ELBW infant from birth as part of usual clinical care. Because no published studies have evaluated the effects of different target SpO2 ranges from birth on important outcomes, this was one of the principle reasons for the design and conduct of the SUPPORT trial.

A number of studies have evaluated different alarm limits, but have not reported the actual durations of SpO2 in the various ranges. Nghiem et al in a PAS abstract this year reported that nurses caring for ELBW infants believe that an acceptable oxygen saturation range should include higher upper limits than

specified by current policy (Nghiem et al, Nursing Opinions and Practices of Oxygenation in Prematures: The NOPOP Study PAS #3415, 2005). The study by Hagadorn reported as a late breaker at the PAS last year (Hagadorn et al, Actual vs Intended Pulse Oxygen Saturation (SpO2) in Infants <28 Weeks Gestation. PAS 2004, Attached) did report on the experience of monitoring the actual SpO2 for 72 hours in the first 4 weeks of life in 78 ELBW infants. They reported that the "lower limits of intended ranges at study centers varied between 83-92%, upper limits 92-98%. Infants were monitored for a median of 70 hours (25th-75th percentiles 67-71 hr) during each of the first 24 weeks. Overall median SpO2 for infants on supplemental O2 during the first 4 weeks was 95% (25th-75th percentiles 91-97%; range of study center medians 91-96%. Centers ranged between 16-71% compliance with their individual intended SpO2 range. Most noncompliance was above intended range." In comparing the SUPPORT data evaluated to date by the DSMC, it is of interest that the mean SpO2 in the 2 Oximeter arms is 90% and 92%, with medians of 92% and 94%, all of which are below that reported by Hagadorn et al (median=95).

The 2 other relevant trials, STOP-ROP and BOOST, both enrolled infants of > 32 weeks postmenstrual age (PMA), and maintained 2 levels of SpO2, 89% to 94% and 91-94% versus 95% to 98% and 96% to 99%, by administration of oxygen. These studies achieved reasonable separation, but did demonstrate substantial overlap of the intended ranges (estimated to be 50% or greater, D Phelps, PI for STOP-ROP). It is important to note that these studies were testing two ranges both of which were higher than the lower range of the SUPPORT trial (85% to 89%) and were treating infants who, for the most part, had recovered from their acute disease. In the BOOST trial 70% of the enrolled infants were < 28 weeks of age at birth (all of SUPPORT is < 28 weeks), 32 weeks PMA, and required oxygen at enrollment (Askie et al, New England Journal of Medicine. 2003; 349(10):959-967). The STOP-ROP trial enrolled infants with pre-threshold ROP at a PMA of 35.4 + 2.5 weeks of age (Phelps et al, Pediatrics. 2000; 105(2):295-310). These trials then gave the higher SpO2 range infants additional oxygen to increase their SpO2 to the desired range. STOP-ROP reported that the infants in the high range had an SpO2 > 95% for > 97% of the monitored time. These studies found an overall increase in pulmonary morbidity in the higher SpO2 range infants.

Examination of oximeter data from one of the NRN sites (Case Western, Walsh et al) obtained for an ongoing study evaluating infants similar to those enrolled in SUPPORT, and managed with conventional oximeters, revealed that for the 9 infants for whom results were available that the percentage of time with and SpO2 > 95% was > 50%.

2. Impact of SUPPORT oximeters algorithm on sat values:

The oximetry algorithm that was designed for the SUPPORT trial is such that re-conversion of the altered oximeter values does not result in a discrete SpO2 number for every displayed value. SpO2 values, of 93%, 94% 95% and 96% will all be reconverted to a single value. As an example, when the actual percent of time at each individual SpO2 point was calculated for this review, in

the 91% to 95% group, there was 5.76% of the time spent at an actual SpO2 of 96% and 8.38% of the time spent at values that represented conversion from readings of 93% to 95%. In the 85% to 89% arm, values of 84%, 85%, 86% and 87% will be reconverted to a single value of 84%. This is a result of having the displayed values return to non-skewed SpO2 values at < 84% and > 96%, a safety design felt to be important by all involved in this trial (See Attached file USCD1). Thus the percentages reported to the DSMC for some of the ranges that include these values were not an accurate representation of the true values. However all values > 96% and < 84% are actual and do not require any conversion.

Percent of time of spent at SpO2 < 84% and > 96%
(RTI, Nov 29, 2005, 14:00 Hrs)

Range **Assigned**	High target (91-95)	Low target (85-89)
< 84%	8.51	16.62
> 96%	22.69	13.60

In the current SUPPORT study, an initial analyses utilizing only unaltered SpO2 values as shown above , ie those below 84% and above 96%, have shown that one arm had an SpO2 > 96% for 13.6% versus 22.69% of the time for the comparison arm, and the duration of an SpO2 < 84% was also different at 16.62% versus 8.51%. The values for SpO2s > 96% using unaltered data suggests that the SUPPORT trial to date has, if anything, reduced the duration of higher oxygen saturations.

In addition, analyses using only actual SpO2 demonstrate that the infants in this trial who are receiving supplemental oxygen are spending approximately 70% of the time with a true SpO2 value between 84% and 96%. We believe that this is information is very encouraging.

3. Impact of inclusion of data from periods in room air on saturation distributions:

As part of the SUPPORT trial, we collect information about inhaled oxygen concentration 3 times a day for the first 14 days and daily thereafter. We believe that an improved documentation of the times when infants are on room air will allow us to determine the saturations during actual oxygen exposure. At the present an infant is considered to be receiving supplemental oxygen if he/she requires oxygen for greater than 2 hours. This results in infants being categorized as receiving supplemental oxygen for significant periods when they are actually in room air. This would result in durations of SpO2 greater than 95% that were felt to be modifiable and reported as such when in fact there is no effective treatment for such elevated SpO2s. In addition, we do not know if such SpO2s on room air are associated with any morbidity. From the SUPPORT study data analyses to date we know that infants in room air have SpO2s > 95% for 46% to 69% of the time.

In view of this design, we would suggest that all future interval analyses for safety examine the ranges of <84% and >96% as those ranges that are considered to be low and high.

We believe that the SUPPORT trial will actually define the periods of time that ELBW infants spend with different ranges of SpO2, and that it is essential to collect this information. In addition, as our findings indicate a lower true percent of the time at SpO2 values >95%, and lower median SpO2 values than has previously been reported, we are in fact, reducing the time with high SpO2 values compared to usual care. The SUPPORT trial carefully evaluates risks, and we will be evaluating group differences for all important short and long term outcomes.

The SUPPORT trial methodology actively encourages all caretakers to keep SpO2 < 96% by having alarm limits set at 85% and 95%. These limits were utilized because it was felt that these represented current practice. The oximetry algorithms were designed to keep infants in the narrower target range of 88% to 92% with the realization that setting alarm limits at these values would severely increase the frequency of the alarms sounding. Nevertheless, our results to date suggest that we have decreased the expected percent of time > 95%, and in one group the value of 14% may be as low as is achievable in an actual clinical environment given the evidence provided by Hagadorn et al and Nghiem et al.

We believe the SUPPORT study will define the distribution and durations of pulse oximetry values among premature infants in highly staffed, dedicated academic centers, and among infants randomized to two different target ranges. For this reason alone, the SUPPORT trial will be very valuable. All of the procedures outlined below in response to your second concern will also allow us to further increase the percentage of time that the infants are in the maximally altered SpO2 ranges which we believe will further increase separation of these groups.

Response to Issue Number 2

There is concern that we have not achieved adequate separation by the current oximeters and study personnel.

1. As described above, the results of additional analyses performed in response to the concerns of the DSMC show differences in the durations of low and high SpO2s between the 2 oximeter groups. A careful analysis of the most recent converted values demonstrates that the cumulative time spent with an SpO2 of 90% or less is 24.3% (91% - 95%) versus 43% (85% - 89%), for the 2 oximeter groups, supporting the ability of the altered oximeters to produce differential SpO2 exposures.

2. We do acknowledge that it would be desirable to increase the percentage of time in the narrower target range and towards this end would propose the following changes to SUPPORT:

A. We will require **documentation that the alarm limits are set and functional as per protocol every 4-6 hours**. We have found that in some units the high alarms are being turned off, and thus believe that such documentation will greatly assist in decreasing the actual time that the SpO2 is > 96%. This task will be assigned to the most appropriate personnel in each unit, which may include bedside or research nurses or respiratory therapists, and this procedure is already being done in many NRN units.

B. We will immediately initiate a **change in our data collection for FiO2 to ensure that subsequent interval reports more accurately reflect saturations measured while on oxygen therapy and exclude saturations of infants in room air.** We will change the data form to indicate that the infant was either in oxygen for the entire 24 hours, and if not, will provide a more accurate estimate of the true time in oxygen, and we will continue with this form of data collection for the entire time that the infant is receiving oxygen. In the current protocol we collect such information 3 times a day for the first 14 days only and then daily thereafter. We believe that more frequent and extended documentation will allow us to determine more accurately the actual time that an infant is in room air. At the present the infant is considered to have spent a day in oxygen if he/she requires oxygen for greater than 2 hours. This results in infants being categorized in oxygen for significant periods when they are in room air. While in room air, we cannot manipulate the SpO2, and thus knowledge of the true time in oxygen will produce a more accurate representation of oximetry results that are subject to care interventions.

C. We will initiate **further training and in-service at all the sites to stress the importance of keeping the SpO2 alarms functional and at the limits of 85% and 95%**. In the past these were guidelines, and we will now change the study manual and protocol to indicate these limits are now set by protocol and that violations will be documented. We will encourage all caretakers to aim for an SpO2 value of 90% and make every effort to educate caretakers to make smaller adjustments in FiO2 and ensure that the infant is maintained between the 87% to 93%, the range with the maximal separation of the study oximeters. We will further facilitate the use of the 2 hour and 12 hour histograms showing the infants' actual ranges to provide feedback to the caretakers regarding the percentage of time in the target ranges.

D. We will develop **guidelines for managing desaturations such that the increase in oxygen is proportional to the desaturation**. More modulated increases in oxygen during these desaturation events will minimize overshoot and the potential of high SpO2 values. We would hope that such changes – ie increasing the FiO2 in steps of 5% as opposed to much larger increases will decrease the resultant overshoots creating the high SpO2 values. This will be included in the revised manual of operations.

E. **We will place bedside cards to indicate the target range**.

F. We will **initiate compliance monitoring visits coordinated by RTI to visit random sites**. These visits had been planned, but had not yet been initiated. The teams will consist of a member of RTI and a study coordinator, and they will review the adherence to the protocol and any other relevant issues.

G. We would recommend that at a minimum, the unblinded oximetry data be reviewed again after an additional 100 to 150 infants have been enrolled in this trial.

We thank the DSMC for their thoughtful concerns. We trust that our plans to move forward with the SUPPORT trial are acceptable to the DSMC. We are anxious to initiate the above changes, seek IRB approvals and re-activate this trial.

LATE BREAKER ABSTRACT SUBMISSION FORM

Abstracts and Payment must be RECEIVED by March 1, 2004

~ Abstracts must be submitted electronically using this form.
~ Abstracts, inclusive of title, authors, institutions, and graphs/tables, must fit in a 6.5 inch x 4 inch space between the two lines (appx. 2,600 characters). Use a font no smaller than 10 pt.
~ You must complete all information and include payment ($50 US) for your abstract to be considered.

Actual vs Intended Pulse Oxygen Saturation (SpO2) in Infants <28 Weeks Gestation

J Hagadorn [1,2], A Furey [1], TH Nghiem [1], S Greene [1], E Abban [1], J Cho [1], P Shrestha [1], A Vora [1], M Landa [2], C Schmid [2], P Hibberd [2], CH Cole [1] and The AVIOx Study Group. [1]Div Newborn Med and [2]Div of Clin Care Research, Tufts-New England Med Ctr, Boston, MA.

Background: Detailed data are not available regarding the actual versus intended SpO2 in infants born <28 weeks gestation (extremely premature newborns, EPNs) in the neonatal period during routine care. **Objective:** To document actual SpO2 in EPNs in the first 4 weeks of life during routine care and compare to the level recommended by local policy/guideline. **Design/Methods:** EPNs <96 hours old were enrolled in a prospective multicenter cohort study. Oximetry data were collected every 2 seconds with masked signal-extraction oximeters for 72 hours in each of the first four weeks of life. Data were compared to SpO2 range prescribed by local institutional policy. **Results:** 14 centers from 3 countries enrolled 78 infants with mean birth weight 863 g (SD 208 g) and mean gestational age 26 wk (SD 1.4 wk). Lower limits of intended ranges at study centers varied between 83-92%, upper limits 92-98%. Infants were monitored for median of 70 hours (25^{th}-75^{th} percentiles 67-71 hr) in each week. Overall median SpO2 for infants on supplemental O2 during the first 4 weeks was 95% (25^{th}-75^{th} percentiles 91-97; range of study center medians 91-96). Centers ranged between 16-71% compliance with intended SpO2 range. Most noncompliance was above intended range. **Conclusions:** Compliance with intended SpO2 range during routine care varied substantially among participating centers, and was generally poor regardless of intended level. These data will assist quality improvement and education efforts, and will aid planning of prospective randomized trials examining level of oxygenation. **Disclosure:** Funded by the SPR Student Research Program; Fight for Sight/Prevent Blindness America; The Tufts-NEMC Research Fund; GCRC/Natl Center for Research Resources MO1-RR00054, and NEI K23 EY/HD00420. Oximeters provided by Masimo Corp.

Briefly describe the reason why the December deadline could not be met:
Study still in progress at December deadline, with only about 60% of enrollment achieved.

Gordon Avery, M.D.
Chairman of the Data Safety Monitoring Committee
NICHD Neonatal Research Network

Dear Dr. Avery,

The SUPPORT Trial Subcommittee and the NICHD Network Steering Committee have reviewed in detail the concerns of the Data Safety Monitoring Committee. We are appreciative of the diligence and thoughtfulness that went into these concerns and we have carefully considered the comments made by the Data Safety Monitoring Committee with respect to both the issue of patient safety and the question of futility relative to the separation of the infants in the two oximetry arms of the trial.

We are very mindful of the need to protect patient safety and toward this end have reviewed the current experience relative to exposure of current ELBW infants to saturations above 95%. There is little information regarding this issue in the literature. We have quoted what we believe to be the relevant recent experiences, including the Network experience with exposures to higher SpO2 ranges. In addition we had asked RTI to provide us with unaltered oximetry data which allows us to look at information for oxygen saturations of 97% or greater and less than 84%, as these values were not altered by the algorithm in place for the study. We also compared the mean and median values of the SpO2 seen in the SUPPORT trial to date with those reported by Hagadorn et al, the only other report that contains such information. This information suggests that our current SpO2 exposures, especially to SpO2 values of 97% and above, for infants within the SUPPORT trial are probably less than is currently being experience outside of the trial, both from the Network experience and in the general practice of neonatology for the ELBW infant. In addition our median SpO2 values for both of our oximetry groups are lower than those reported by Hagadorn et al.

We agree that we should aim for greater separation between the oximetry groups, and are pleased that we are seeing some differences on SpO2 exposure between the groups. I have detailed our responses to each of the DSMC's concerns in the attached review. We believe that with these changes to the Protocol and Manual of operations and additional in-service at the sites coupled with intermittent site visits, that we will attain an even greater SpO2 separation and differential oxygen exposure for our 2 study groups. We would also like to recommend a re-evaluation of this data after an additional 100-150 infants have been enrolled.

We thank you and your committee for your careful review and suggestions. We hope that our responses are appropriate and that we may be allowed to continue this important trial

Sincerely,

Neil N. Finer, M.D.
Principal Investigator on behalf of the SUPPORT Subcommittee

Date: Friday, December 02, 2005 9:23:21 AM

We will have all the analysis of the pulse ox data ready by late Monday for all kids in SUPPORT. We plan to send this to Neil at that time. He can then update his response to the DSMC with the latest numbers, which, if current trends hold, will make it stronger. So, I think we may want to hold off on sending this to the DSMC until then.

Thanks

Abhik

Yes, I believe Neil sent them. I'll plan to send them the following:
Agenda and list of participants
List of members with their specialty, etc.
SUPPORT Protocol
Letter of Response from the Steering Committee
The two abstracts.

Anything else?

I have the Dec 13 call on my calendar. Please send, ahead of time, the current roster of DSMC Committee, NIH rep, RTI major players, with e-mail and phone numbers. The DSMC members could also be characterized as to specialty. This will aid us all in being present to one another under the current practice of no meetings, all conference calls. In light of what we will be discussing, we should also have, in advance of the call, the SUPPORT protocol and the Steering Committee proposal for continuing, if there is such. We need to do reading and thinking in advance of the call. Thanks. Gordon

Attachments:	Percent of time spent at each SpO2 value.doc

Hi Abbot
We are all concerned about any more data collection and our present solution is to declare a day an oxygen or room air day based on the greater percentage of time in oxygen for that day. I also agree that while we want more FiO2 data, I think RTI already feels overloaded with the oximeter data. We did discuss changing the alarms to lower than 84% and higher than 95% but most feel that the current range is most acceptable.
In addition, we do have some separation in the SpO2 exposures of the 2 oximeter groups. More would be better and all of our efforts should help that. I do not know how much more we need. If one calculates the differences that we are currently seeing, then in a given day the infants in 1 arm of the study are spending 18% more time with an SpO2 less than 90% than the other group, that represents about 4 hours per day. The same group also spends about 9% less of the time with an SpO2 above 97%.
I know that you have an interest in this data and so I am sending you the additional data that we had run and about 60 babies. RTI could not do more babies as this tied up all their computers.
I have not shared this outside the Subcommittee so as not to get everyone possibly more confused.
We do have differences, and more is probably better, but we are creating 2 different SpO2 exposures.
Thanks for sharing your concerns Abbot
Be well
Neil

Neil
I agree with the document that you have very nicely put together but I am still concerned that the additional data to collect (issue 2, number 2) to determine whether infants are in oxygen or room air will not be sufficiently accurate. At least at Brown and Parkland the FiO2 is recorded hourly and obviously tells little about how much oxygen they are in for time intervals inbetween these documentations. I think this issue needs to be considered further since I am afraid that you will still be lumping infants in room air with infants in oxygen. Secondly I have real concerns that we can adequately keep these infants in the goal ranges desired given their lability; should there be consideration to wider goal ranges for each group? Abbot

Thanks Richard
I have made the clarifications

Corrected Hagadorn et al to 2004 and the n=78 and clarified for each of the 4 weeks. And I have stated for greater than 2 hours
In answer to your question – any oxygen more than 2 hours is a yes for oxygen after 14 days
The next query – I have clarified the actual groups and yes, these were additional data runs that we asked RTI to perform
". As described above, the results of additional analyses performed in response to the concerns of the DSMC show differences in the durations of low and high SpO2s between the 2 oximeter groups. A careful analysis of the most recent converted values demonstrates that the cumulative time spent with an SpO2 of 90% or less is 24.3% (91% - 95%) versus 43% (85% - 89%), for the 2 oximeter groups, supporting the ability of the altered oximeters to produce differential SpO2 exposures."
#4- I have changed that to read ".We have found that in some units the high alarms are being turned off, and thus believe that such documentation will greatly assist in decreasing the actual time that the SpO2 is > 96%. This task will be assigned to the most appropriate personnel in each unit, which may include bedside or research nurses or respiratory therapists, and this procedure is already being done in many NRN units"

We added "to have spent a day" as you suggested.
Many thanks to you and tour team for these suggestions
Be well
Neil

Subject: Re: Response to DSMC Steering Nov 30 05

Hi,
This is an excellent response to the DSMC. Our SUPPORT team has reviewed it and finds it acceptable. I have several minor comments/revisions to offer:
1. Hagadorn's PAS abstract is from 2004 not 2005; at least the version that was sent with the materials indicated 2004. Also in discussion about that abstract, revise the sentence to indicate that the infants were monitored for 72 hrs each week during the first 4 weeks. The current sentence is unclear. Finally, the abstract refers to 78 infants not 72 infants.
2.Response 1, paragraph 6, sentence 3: This sentence is confusing. Does this mean that supplemental oxygen for > 2 hrs on a day led to classifying that day as a day in oxygen?
3. Response 2, paragraph 1, sentence 3: I found this sentence confusing. Can you simplify it and make it clear to which groups the cumulative times are assigned? Also do these values refer to the values included in the DSMC report or to other calculations? That was not clear to me.
4. Response 2, #1: Why must that task be assigned to RTs? I suggest that you make this a little more flexible, since RTs may not be involved in setting alarm limits in some units. Research nurses at Yale have performed that task for this trial. 5.Response 2, #2, sentence 5: I suggest the following revision to this sentence;""At the present the infant is considered to

have spent a day in oxygen if....

I hope these minor comments are helpful.
Richard

> Hi Carl Dale and Rose
> Thank you for your suggestions, all of which have been incorporated in the current revision. We do have a strategy if the decision is to close this arm. Rose and I have discussed this, and I would rather be hopeful that we can convince the DSMC that we be allowed to move ahead. If the DSMC decides to recommend that we close the oximetry arm on the basis of the concerns expressed to us, and the lack of any evidence, then I would ask I and any others who wish to accompany me be allowed to have a face to face meeting with the DSMC and Dr Alexander.
> There is no safety issue, and we do have a degree of separation. More would be unequivocally better, but there is no evidence that we have reached futility. We have not even analyzed the FiO2 data to determine if the 2 groups have different oxygen exposures. The Network needs to strenuously defend our ability to complete well designed and potentially useful trials from premature closure. I was involved the stopping of NINOS, (for efficacy, I was opposed as was Richard) and participated in PINO, (stopped without unequivocal evidence).
> For me, if the decision is to stop the oximetry arm on the basis of the current findings, the continuation of SUPPORT in its entirety at this time is an issue that I am prepared to go the distance on. I realize that this may not be the view of everyone, and I will bear that responsibility alone.

Hi Neil and Rose,

I'm catching up with the East Coast morning. Reading Carl's note below, I am reminded that the DSMC has called for a STOP to this trial. I am hopeful that we'll be persuavsive, but it is not a done deal.

Do we need to be preparing to move forward with only the two ventilation arms? Should that be mentioned in the letter? I have conflicting thoughts about that -- don't bring it up at this time probably. I think we'd rather not give them an 'easy path' and therefore we still should advocate for the full 2x2 study. (with all the cautions in our 'second issue' review.

Subject: RE:

Neil,

The revised response looks good overall. I guess I'm more of a glass-half-empty person on this, but all the available data suggest to me that centers have so far been unable to comply with the protocol targets (particularly in the 85-89% group) and that the separation between groups is less than that achieved in other similar studies. I share the DSMB's concern that, without significant improvement in compliance to protocol, the oximetry comparison could be futile. As a result, the tone of the response to Issue #2 seems a bit too sunny to me, and I worry that the DSMB will view it as Pollyanna-ish. That being said, you've suggested all the appropriate steps to try to improve and monitor compliance, so I agree completely with the actions you lay out.

A couple of minor typographical things:

In Issue 2, B, I think you mean "either in or out of oxygen for the

entire 24 hours, and if not,...."

"Exposures" rather than "esxposures" in the letter.

All these comments are for your information only. Dale has the final vote from our center.

Thanks again for your work on this.

Carl

<<Response to DSMC Steering Final.doc>> <<Avery Letter.doc>>

In response to the comments and concerns of the DSMC, the SUPPORT committee held a conference call Monday Nov 28th at 10:00 to 1130AM to prepare a response.

- The DSMC made the following 2 comments in their letter regarding the SUPPORT trial. This was generated after they reviewed the oximeter data, which was corrected back to actual SpO2 values from the altered values displayed at the bedside:

1. There is a significant safety and exposure issue for the infants in the high saturation treatment group because an unacceptably high proportion of time was spent by these study subjects in the >95% range

2. There is a futility concern for this arm of the trial in that there does not appear to be substantial separation between the two high and low saturation treatment groups, and the babies are not being kept in the target range the appropriate amount of time in order to meaningfully test the oxygen saturation intervention as originally designed.

Based on these two issues, the consensus of the Committee was to recommend stopping the oxygen saturation arms of the SUPPORT trial due to safety and futility concerns.

We have responded to each of these concerns and our responses are detailed below

Response to Issue Number 1

We appreciate the concern expressed by the DSMC regarding a potential safety issue secondary to durations of SpO2 values greater than 95%.

1. Review of existing evidence and practice regarding durations of higher SpO2 values:

To date there are no prospective data which define the SpO2s experienced by the ELBW infant from birth as part of usual clinical care. Because no published studies have evaluated the effects of different target SpO2 ranges on important outcomes, this was one of the principle reasons for the design and conduct of the SUPPORT trial.

A number of studies have evaluated different alarm limits, but have not reported the actual durations of SpO2 in the various ranges. Nghiem et al in a PAS abstract this year reported that nurses caring for ELBW infants believe that an acceptable oxygen saturation range should include higher upper limits than specified by current policy (Nghiem et al, Nursing Opinions and Practices of Oxygenation in Prematures: The NOPOP Study PAS #3415, 2005). The study by Hagadorn reported as a late breaker at the PAS this year (Hagadorn et al, Actual vs Intended Pulse Oxygen Saturation (SpO2) in Infants <28 Weeks Gestation. PAS 2005, Attached) did report on the experience of monitoring the

actual SpO2 for 72 hours in the first 4 weeks of life in 72 ELBW infants. They reported that the "lower limits of intended ranges at study centers varied between 83-92%, upper limits 92-98%. Infants were monitored for a median of 70 hours (25th-75th percentiles 67-71 hr) during each week. Overall median SpO2 for infants on supplemental O2 during the first 4 weeks was 95% (25th-75th percentiles 91-97%; range of study center medians 91-96%. Centers ranged between 16-71% compliance with their individual intended SpO2 range. Most noncompliance was above intended range." In comparing the SUPPORT data evaluated to date by the DSMC, it is of interest that the mean SpO2 in the 2 Oximeter arms is 90% and 92%, with medians of 92% and 94%, all of which are below that reported by Hagadorn et al (median=95).

The 2 other relevant trials, STOP-ROP and BOOST, both enrolled infants at about 32 weeks PCA, and maintained 2 levels of SpO2, 89% to 94% and 91-94% versus 95% to 98% and 96% to 99%, by administration of oxygen. These studies achieved reasonable separation, but did demonstrate substantial overlap of the intended ranges. It is important to note that these studies were testing two ranges both of which were higher than the lower range of the SUPPORT trial (85% to 89%) and were treating infants who, for the most part, had recovered from their acute disease. In the BOOST trial 70% of the enrolled infants were < 28 weeks of age at birth (all of SUPPORT is < 28 weeks), 32 weeks postmenstrual age (PMA), and required oxygen at enrollment (Askie et al, New England Journal of Medicine. 2003; 349(10):959-967). The STOP-ROP trial enrolled infants with pre-threshold ROP at a PMA of 35.4 + 2.5 weeks of age (Phelps et al, Pediatrics. 2000; 105(2):295-310). These trials then gave the higher SpO2 range infants additional oxygen to increase their SpO2 to the desired range. STOP-ROP reported that the infants in the high range had an SpO2 > 95% for > 97% of the monitored time. These studies found an overall increase in pulmonary morbidity in the higher SpO2 range infants.
Examination of oximeter data from one of the NRN sites (Case Western, Walsh et al) obtained for an ongoing study evaluating infants similar to those enrolled in SUPPORT, and managed with conventional oximeters revealed that for the 9 infants for whom results were available that the percentage of time with an SpO2 > 95% was > 50%.

2. Impact of SUPPORT oximeters algorithm on sat values:

The oximetry algorithm that was designed for the SUPPORT trial is such that re-conversion of the altered oximeter values does not result in a discrete SpO2 number for every displayed value. SpO2 values, of 93%, 94% 95% and 96% will all be reconverted to a single value. As an example, when the actual percent of time at each individual SpO2 point was calculated for this review, in the 91% to 95% group, there was 5.76% of the time spent at an actual SpO2 of 96% and 8.38% of the time spent at values that represented conversion from readings of 93% to 95%. In the 85% to 89% arm, values of 84%, 85%, 86% and 87% will be reconverted to a single value of 84%. This is a result of having the displayed values return to non-skewed SpO2 values at < 84% and > 96%, a safety design felt to be important by all involved in this trial (See Attached file

USCD1). Thus the percentages reported to the DSMC for some of the ranges that include these values were not an accurate representation of the true values. However all values > 96% and < 84% are actual and do not require any conversion.

Percent of time of spent at SpO2 < 84% and > 96%
(RTI, Nov 29, 2005, 14:00 Hrs)

Range **Assigned**	High target (91-95)	Low target (85-89)
< 84%	8.51	16.62
> 96%	22.69	13.60

In the current SUPPORT study, an initial analyses utilizing only unaltered SpO2 values as shown above , ie those below 84% and above 96% have shown that one arm had an SpO2 > 96% for 13.6% versus 22.69% of the time for the comparison arm, and the duration of an SpO2 < 84% was also different at 16.62% versus 8.51%. The previously reported value of 36% duration of an SpO2 > 95% for one group represented an artifact of the conversion algorithm as described above. The values for SpO2s > 96% using unaltered data suggests that the SUPPORT trial to date has, if anything, reduced the duration of higher oxygen saturations.

In addition, analyses using only actual SpO2 demonstrate that the infants in this trial who are receiving supplemental oxygen are spending approximately 70% of the time with a true SpO2 value between 84% and 96%. We believe that this is information is very encouraging.

3. Impact of inclusion of data from periods in room air on saturation distributions:

As part of the SUPPORT trial, we collect information about inhaled oxygen concentration 3 times a day for the first 14 days and daily thereafter. We believe that a more frequent documentation of the times when infants are on room air will allow us to determine the saturations during actual oxygen exposure. At the present an infant is considered to be receiving supplemental oxygen if he/she requires oxygen for greater than 2 hours. This results in infants being categorized as receiving supplemental oxygen for significant periods when they are actually in room air. This would result in durations of SpO2 greater than 95% that were felt to be modifiable and reported as such when in fact there is no effective treatment for such elevated SpO2s. In addition, we do not know if such SpO2s on room air are associated with any morbidity. From the SUPPORT study data analyses to date we know that infants in room air have SpO2s > 95% for 46% to 69% of the time.

In view of this design, we would suggest that all future interval analyses examine the ranges of <84% and >96% as those ranges that are considered to be low and high.

We believe that the SUPPORT trial will actually define the periods of time that ELBW infants spend with different ranges of SpO2, and that it is essential to collect this information. In addition, as our findings indicate a lower true percent of the time at SpO2 values >95%, and lower median SpO2 values than has previously been reported, we are in fact, reducing the time with high SpO2 values compared to usual care. The SUPPORT trial carefully evaluates risks, and we will be evaluating group differences for all important short and long term outcomes.

The SUPPORT trial methodology actively encourages all caretakers to keep SpO2 < 96% by having alarm limits set at 85% and 95%. These limits were utilized because it was felt that these represented current practice. The oximetry algorithms were designed to keep infants in the narrower target range of 88% to 92% with the realization that setting alarm limits at these values would severely increase the frequency of the alarms sounding. Nevertheless, our results to date suggest that we have decreased the expected percent of time > 95%, and in one group the value of 14% may be as low as is achievable in an actual clinical environment.

We believe the SUPPORT study will define the distribution and durations of pulse oximetry values among premature infants in highly staffed, dedicated academic centers, and among infants randomized to two different target ranges. For this reason alone, the SUPPORT trial will be very valuable. All of the procedures outlined below in response to your second concern will also allow us to further increase the percentage of time that the infants are in the maximally altered SpO2 ranges which we believe will further increase separation of these groups.

Response to Issue Number 2

There is concern that we have not achieved adequate separation by the current oximeters and study personnel.

1. As described above, the newest analyses show differences in the durations of low and high SpO2s between the 2 oximeter groups. A careful analysis of the most recent converted values demonstrates that the cumulative time spent with an SpO2 of 90% or less is 24.3% versus 43%, for the 2 oximeter groups, supporting the ability of the altered oximeters to produce differential SpO2 exposures.

2. We do acknowledge that it would desirable to increase the percentage of time in the narrower target range and towards this end would propose the following changes to SUPPORT:

A. We will require **documentation that the alarm limits are set and functional as per protocol every 4-6 hours**. We have found that in some units the high alarms are being defeated, and thus believe that such documentation will greatly assist in decreasing the actual time that the SpO2 is > 96%. This task will be

assigned to the respiratory therapists, and this procedure is already being done in many NRN units.

B. We will immediately initiate a **change in our data collection for FiO2 to ensure that subsequent interval reports more accurately reflect saturations measured while on oxygen therapy and exclude saturations of infants in room air.** We will change the data form to indicate that the infant was either in oxygen for the entire 24 hours, and if not, will check off the actual hours of oxygen exposure, and we will continue with this form of data collection for the entire time that the infant is receiving oxygen. In the current protocol we collect such information 3 times a day for the first 14 days only and then daily thereafter. We believe that more frequent and extended documentation will allow us to determine the actual time that an infant is in room air. At the present the infant is considered in oxygen if he/she requires oxygen for greater than intermittent use. This results in infants being categorized in oxygen for significant periods when they are in room air. While in room air, we cannot manipulate the SpO2, and thus knowledge of the true time in oxygen will produce a more accurate representation of oximetry results that are subject to care interventions.

C. We will initiate **further training and in-service at all the sites to stress the importance of keeping the SpO2 alarm functional and at the limits of 85% and 95%**. In the past these were guidelines, and we will now change the study manual and protocol to indicate these limits are now set by protocol and that violations will be documented. We will encourage all caretakers to aim for an SpO2 value of 90% and make every effort to educate caretakers to make smaller adjustments in FiO2 and ensure that the infant is maintained between the 87% to 93%, the range with the maximal separation of the study oximeters. We will further facilitate the use of the 2 hour and 12 hour histograms showing the infants' actual ranges to provide feedback to the caretakers regarding the percentage of time in the target ranges.

D. We will develop **guidelines for managing desaturations such that the increase in oxygen is proportional to the desaturation**. More modulated increases in oxygen during these desaturation events will minimize overshoot and the potential of high SpO2 values. We would hope that such changes – ie increasing the FiO2 in steps of 5% as opposed to much larger increases will decrease the resultant overshoots creating the high SpO2 values. This will be included in the revised manual of operations.

E. **We will place bedside cards to indicate the target range**.

F. We will **initiate compliance monitoring visits coordinated by RTI to visit random sites**. These visits had been planned, but had not yet been initiated. The teams will consist of a member of RTI and a study coordinator, and they will review the adherence to the protocol and any other relevant issues.

G. We would recommend that at a minimum, the unblinded oximetry data be reviewed again after an additional 100 to 150 infants have been enrolled in this trial.

We thank the DSMC for their thoughtful concerns. We trust that our plans to move forward with the SUPPORT trial are acceptable to the DSMC. We are anxious to initiate the above changes, seek IRB approvals and re-activate this trial.

Gordon Avery, M.D.
Chairman of the Data Safety Monitoring Committee
NICHD Neonatal Research Network

Dear Dr. Avery,

The SUPPORT Trial Subcommittee and the NICHD Network Steering Committee have reviewed in detail the concerns of the Data Safety Monitoring Committee. We are appreciative of the diligence and thoughtfulness that when into these concerns and we have carefully considered the comments made by the Data Safety Monitoring Committee with respect to both the issue of patient safety and the question of futility relative to the separation of the infants in the two oximetry arms of the trial.

We are very mindful of the need to protect patient safety and toward this end have reviewed the current experience relative to exposure of current ELBW infants to saturations above 95%. As you are well aware, there is little information regarding this in the literature. We have quoted what we believe to be the relevant recent experiences, including the Network experience with exposures to higher SpO2 ranges. In addition we had asked RTI to provide us with unaltered oximetry data which allows us to look at information for oxygen saturations of 97% or greater and less than 84%, as these values were not altered by the algorithm in place for the study. We also compared the mean and median values of the SpO2 seen in the SUPPORT trial to date with those reported by Hagadorn et al, the only other report that contains such information. This information suggests that our current SpO2 exposures, especially to SpO2 values of 97% and above, for infants within the SUPPORT trial are probably less than is currently being experience outside of the trial, both from the Network experience and in the general practice of neonatology for the ELBW infant. In addition our median SpO2 values for both of our oximetry groups are lower than those reported by Hagadorn et al.

We agree that we should aim for greater separation between the oximetry groups, and are pleased that we are seeing some differences on SpO2 exposure between the groups. I have detailed our responses to each of the DSMCs concerns in the attached review. We believe that with these changes to the protocol and Manual of operations and additional in-service at the sites coupled with intermittent site visits, that we will attain an even greater SpO2 separation and differential oxygen exposure for our 2 study groups. We would also like to recommend a re-evaluation of this data after an additional 100-150 infants have been enrolled.

We thank you and your committee for your careful review and suggestions. We hope that our responses are appropriate and that we may be allowed to continue this important trial

Sincerely,

Neil N. Finer, M.D.
Principal Investigator on behalf of the SUPPORT Subcommittee

Hi Rose
Here is the current revision with the changes suggested by Dale, Carl, Shanaz, and Michele. Ron suggested a letter to the DSMC – I think this is a good idea, please review and see if I have set the correct tone.
I will respond further if I get further ideas. Thanks to everyone for their input.
Neil

In response to the comments and concerns of the DSMC, the SUPPORT committee held a conference call Monday Nov 28th at 10:00 to 1130AM to prepare a response.

- The DSMC made the following 2 comments in their letter regarding the SUPPORT trial. This was generated after they reviewed the oximeter data, which was corrected back to actual SpO2 values from the altered values displayed at the bedside:

1. There is a significant safety and exposure issue for the infants in the high saturation treatment group because an unacceptably high proportion of time was spent by these study subjects in the >95% range

2. There is a futility concern for this arm of the trial in that there does not appear to be substantial separation between the two high and low saturation treatment groups, and the babies are not being kept in the target range the appropriate amount of time in order to meaningfully test the oxygen saturation intervention as originally designed.

Based on these two issues, the consensus of the Committee was to recommend stopping the oxygen saturation arms of the SUPPORT trial due to safety and futility concerns.

We have responded to each of these concerns and our responses are detailed below

Response to Issue Number 1

We appreciate the concern expressed by the DSMC regarding a potential safety issue secondary to durations of SpO2 values greater than 95%.

1. Review of existing evidence and practice regarding durations of higher SpO2 values:

To date there are no prospective data which define the SpO2s experienced by the ELBW infant from birth as part of usual clinical care. Because no published studies have evaluated the effects of different target SpO2 ranges on important outcomes, this was one of the principle reasons for the design and conduct of the SUPPORT trial.

A number of studies have evaluated different alarm limits, but have not reported the actual durations of SpO2 in the various ranges. Nghiem et al in a PAS abstract this year reported that nurses caring for ELBW infants believe that an acceptable oxygen saturation range should include higher upper limits than specified by current policy (Nghiem et al, Nursing Opinions and Practices of Oxygenation in Prematures: The NOPOP Study PAS #3415, 2005). The study by Hagadorn reported as a late breaker at the PAS this year (Hagadorn et al, Actual vs Intended Pulse Oxygen Saturation (SpO2) in Infants <28 Weeks Gestation. PAS 2005, Attached) did report on the experience of monitoring the

actual SpO2 for 72 hours in the first 4 weeks of life in 72 ELBW infants. They reported that the "lower limits of intended ranges at study centers varied between 83-92%, upper limits 92-98%. Infants were monitored for a median of 70 hours (25th-75th percentiles 67-71 hr) during each week. Overall median SpO2 for infants on supplemental O2 during the first 4 weeks was 95% (25th-75th percentiles 91-97%; range of study center medians 91-96%. Centers ranged between 16-71% compliance with their individual intended SpO2 range. Most noncompliance was above intended range." In comparing the SUPPORT data evaluated to date by the DSMC, it is of interest that the mean SpO2 in the 2 Oximeter arms is 90% and 92%, with medians of 92% and 94%, all of which are below that reported by Hagadorn et al (median=95).

The 2 other relevant trials, STOP-ROP and BOOST, both enrolled infants at about 32 weeks PCA, and maintained 2 levels of SpO2, 89% to 94% and 91-94% versus 95% to 98% and 96% to 99%, by administration of oxygen. These studies achieved reasonable separation, but did demonstrate substantial overlap of the intended ranges. It is important to note that these studies were testing two ranges both of which were higher than the lower range of the SUPPORT trial (85% to 89%) and were treating infants who, for the most part, had recovered from their acute disease. In the BOOST trial 70% of the enrolled infants were < 28 weeks of age at birth (all of SUPPORT is < 28 weeks), 32 weeks postmenstrual age (PMA), and required oxygen at enrollment (Askie et al, New England Journal of Medicine. 2003; 349(10):959-967). The STOP-ROP trial enrolled infants with pre-threshold ROP at a PMA of 35.4 + 2.5 weeks of age (Phelps et al, Pediatrics. 2000; 105(2):295-310). These trials then gave the higher SpO2 range infants additional oxygen to increase their SpO2 to the desired range. STOP-ROP reported that the infants in the high range had an SpO2 > 95% for > 97% of the monitored time. These studies found an overall increase in pulmonary morbidity in the higher SpO2 range infants.
Examination of oximeter data from one of the NRN sites (Case Western, Walsh et al) obtained for an ongoing study evaluating infants similar to those enrolled in SUPPORT, and managed with conventional oximeters revealed that for the 9 infants for whom results were available that the percentage of time with and SpO2 > 95% was > 50%.

2. Impact of SUPPORT oximeters algorithm on sat values:

The oximetry algorithm that was designed for the SUPPORT trial is such that re-conversion of the altered oximeter values does not result in a discrete SpO2 number for every displayed value. SpO2 values, of 93%, 94% 95% and 96% will all be reconverted to a single value. As an example, when the actual percent of time at each individual SpO2 point was calculated for this review, in the 91% to 95% group, there was 5.76% of the time spent at an actual SpO2 of 96% and 8.38% of the time spent at values that represented conversion from readings of 93% to 95%. In the 85% to 89% arm, values of 84%, 85%, 86% and 87% will be reconverted to a single value of 84%. This is a result of having the displayed values return to non-skewed SpO2 values at < 84% and > 96%, a safety design felt to be important by all involved in this trial (See Attached file

USCD1). Thus the percentages reported to the DSMC for some of the ranges that include these values were not an accurate representation of the true values. However all values > 96% and < 84% are actual and do not require any conversion.

Percent of time of spent at SpO2 < 84% and > 96%
(RTI, Nov 29, 2005, 14:00 Hrs)

Range **Assigned**	High target (91-95)	Low target (85-89)
< 84%	8.51	16.62
> 96%	22.69	13.60

In the current SUPPORT study, an initial analyses utilizing only unaltered SpO2 values as shown above , ie those below 84% and above 96% have shown that one arm had an SpO2 > 96% for 13.6% versus 22.69% of the time for the comparison arm, and the duration of an SpO2 < 84% was also different at 16.62% versus 8.51%. The previously reported value of 36% duration of an SpO2 > 95% for one group represented an artifact of the conversion algorithm as described above. The values for SpO2s > 96% using unaltered data suggests that the SUPPORT trial to date has, if anything, reduced the duration of higher oxygen saturations.

In addition, analyses using only actual SpO2 demonstrate that the infants in this trial who are receiving supplemental oxygen are spending approximately 70% of the time with a true SpO2 value between 84% and 96%. We believe that this is information is very encouraging.

3. Impact of inclusion of data from periods in room air on saturation distributions:

As part of the SUPPORT trial, we collect information about inhaled oxygen concentration 3 times a day for the first 14 days and daily thereafter. We believe that a more frequent documentation of the times when infants are on room air will allow us to determine the saturations during actual oxygen exposure. At the present an infant is considered to be receiving supplemental oxygen if he/she requires oxygen for greater than 2 hours. This results in infants being categorized as receiving supplemental oxygen for significant periods when they are actually in room air. This would result in durations of SpO2 greater than 95% that were felt to be modifiable and reported as such when in fact there is no effective treatment for such elevated SpO2s. In addition, we do not know if such SpO2s on room air are associated with any morbidity. From the SUPPORT study data analyses to date we know that infants in room air have SpO2s > 95% for 46% to 69% of the time.

In view of this design, we would suggest that all future interval analyses examine the ranges of <84% and >96% as those ranges that are considered to be low and high.

We believe that the SUPPORT trial will actually define the periods of time that ELBW infants spend with different ranges of SpO2, and that it is essential to collect this information. In addition, as our findings indicate a lower true percent of the time at SpO2 values >95%, and lower median SpO2 values than has previously been reported, we are in fact, reducing the time with high SpO2 values compared to usual care. The SUPPORT trial carefully evaluates risks, and we will be evaluating group differences for all important short and long term outcomes.

The SUPPORT trial methodology actively encourages all caretakers to keep SpO2 < 96% by having alarm limits set at 85% and 95%. These limits were utilized because it was felt that these represented current practice. The oximetry algorithms were designed to keep infants in the narrower target range of 88% to 92% with the realization that setting alarm limits at these values would severely increase the frequency of the alarms sounding. Nevertheless, our results to date suggest that we have decreased the expected percent of time > 95%, and in one group the value of 14% may be as low as is achievable in an actual clinical environment.

We believe the SUPPORT study will define the distribution and durations of pulse oximetry values among premature infants in highly staffed, dedicated academic centers, and among infants randomized to two different target ranges. For this reason alone, the SUPPORT trial will be very valuable. All of the procedures outlined below in response to your second concern will also allow us to further increase the percentage of time that the infants are in the maximally altered SpO2 ranges which we believe will further increase separation of these groups.

Response to Issue Number 2

There is concern that we have not achieved adequate separation by the current oximeters and study personnel.

1. As described above, the newest analyses show differences in the durations of low and high SpO2s between the 2 oximeter groups. A careful analysis of the most recent converted values demonstrates that the cumulative time spent with an SpO2 of 90% or less is 24.3% versus 43%, for the 2 oximeter groups, supporting the ability of the altered oximeters to produce differential SpO2 exposures.

2. We do acknowledge that it would desirable to increase the percentage of time in the narrower target range and towards this end would propose the following changes to SUPPORT:

A. We will require **documentation that the alarm limits are set and functional as per protocol every 4-6 hours**. We have found that in some units the high alarms are being defeated, and thus believe that such documentation will greatly assist in decreasing the actual time that the SpO2 is > 96%. This task will be

assigned to the respiratory therapists, and this procedure is already being done in many NRN units.

B. We will immediately initiate a **change in our data collection for FiO2 to ensure that subsequent interval reports more accurately reflect saturations measured while on oxygen therapy and exclude saturations of infants in room air.** We will change the data form to indicate that the infant was either in oxygen for the entire 24 hours, and if not, will check off the actual hours of oxygen exposure, and we will continue with this form of data collection for the entire time that the infant is receiving oxygen. In the current protocol we collect such information 3 times a day for the first 14 days only and then daily thereafter. We believe that more frequent and extended documentation will allow us to determine the actual time that an infant is in room air. At the present the infant is considered in oxygen if he/she requires oxygen for greater than intermittent use. This results in infants being categorized in oxygen for significant periods when they are in room air. While in room air, we cannot manipulate the SpO2, and thus knowledge of the true time in oxygen will produce a more accurate representation of oximetry results that are subject to care interventions.

C. We will initiate **further training and in-service at all the sites to stress the importance of keeping the SpO2 alarm functional and at the limits of 85% and 95%**. In the past these were guidelines, and we will now change the study manual and protocol to indicate these limits are now set by protocol and that violations will be documented. We will encourage all caretakers to aim for an SpO2 value of 90% and make every effort to educate caretakers to make smaller adjustments in FiO2 and ensure that the infant is maintained between the 87% to 93%, the range with the maximal separation of the study oximeters. We will further facilitate the use of the 2 hour and 12 hour histograms showing the infants' actual ranges to provide feedback to the caretakers regarding the percentage of time in the target ranges.

D. We will develop **guidelines for managing desaturations such that the increase in oxygen is proportional to the desaturation**. More modulated increases in oxygen during these desaturation events will minimize overshoot and the potential of high SpO2 values. We would hope that such changes – ie increasing the FiO2 in steps of 5% as opposed to much larger increases will decrease the resultant overshoots creating the high SpO2 values. This will be included in the revised manual of operations.

E. We will place bedside cards to indicate the target range.

F. We will **initiate compliance monitoring visits coordinated by RTI to visit random sites**. These visits had been planned, but had not yet been initiated. The teams will consist of a member of RTI and a study coordinator, and they will review the adherence to the protocol and any other relevant issues.

G. We would recommend that at a minimum, the unblinded oximetry data be reviewed again after an additional 100 to 150 infants have been enrolled in this trial.

We thank the DSMC for their thoughtful concerns. We trust that our plans to move forward with the SUPPORT trial are acceptable to the DSMC. We are anxious to initiate the above changes, seek IRB approvals and re-activate this trial.

Gordon Avery, M.D.
Chairman of the Data Safety Monitoring Committee
NICHD Neonatal Research Network

Dear Dr. Avery,

The SUPPORT Trial Subcommittee and the NICHD Network Steering Committee have reviewed in detail the concerns of the Data Safety Monitoring Committee. We are appreciative of the diligence and thoughtfulness that when into these concerns and we have carefully considered the comments made by the Data Safety Monitoring Committee with respect to both the issue of patient safety and the question of futility relative to the separation of the infants in the two oximetry arms of the trial.

We are very mindful of the need to protect patient safety and toward this end have reviewed the current experience relative to exposure of current ELBW infants to saturations above 95%. As you are well aware, there is little information regarding this in the literature. We have quoted what we believe to be the relevant recent experiences, including the Network experience with esxposures to higher SpO2 ranges. In addition we had asked RTI provide us with unaltered oximetry data which allows us to look at information for oxygen saturations of 97% or greater and less than 84%, as these values were not altered by the algorithm in place for the study. We also compared the mean and median values of the SpO2 seen in the SUPPORT trial to date with those reported by Hagadorn et al, the only other report that contains such information. This information suggests that our current SpO2 exposures, especially to SpO2 values of 97% and above, for infants within the SUPPORT trial are probably less than is currently being experience outside of the trial, both from the Network experience and in the general practice of neonatology for the ELBW infant. In addition our median SpO2 values for both of our oximetry groups are lower than those reported by Hagadorn et al.

We agree that we should aim for greater separation between the oximetry groups, and are pleased that we are seeing some differences on SpO2 exposure between the groups. I have detailed our responses to each of the DSMCs concerns in the attached review. We believe that with these changes to the protocol and Manual of operations and additional in-service at the sites coupled with intermittent site visits, that we will attain an even greater SpO2 separation and differential oxygen exposure for our 2 study groups. We would also like to recommend a re-evaluation of this data after an additional 100-150 infants have been enrolled.

We thank you and your committee for your careful review and suggestions. We hope that our responses are appropriate and that we may be allowed to continue this important trial

Sincerely,

Neil N. Finer, M.D.

Hi Carl
All great ideas! I will definitely add a re-evaluation after the next 100-150 infants at a minimum. I agree with you that the curves may show less separation than we want, and I would ague that we make changes to ensure better separation than we have achieved. Wally is our guru regarding best performance with oximeters, and we asking Wally to guide us in the education process to get better compliance.
Many thanks for these thoughtful comments
Neil

Subject: RE: Response to DSMC Steering Nov 30 05

Dear Rose and Neil,

I have a few additional suggestions that I didn't have the opportunity to make before I needed to leave the call.

1. The response to "Issue #1" looks fine and addresses the issue cogently and completely.

2. The response to "Issue #2" is reassuring in that there is some separation between the groups. However, it's difficult for me to assess completely how similar or different the degree of separation is from those achieved in other studies (STOP-ROP and BOOST). From an empirical point of view, STOP-ROP appeared to have an offset of 5% of group medians (92% vs. 97%, at least for the median of the medians from Table 4 in the paper) and had a measurable physiologic effect. BOOST had an offset of 4% of group medians (93% vs. 97% in legend of Figure 1 of the paper) and had no measurable physiologic effect. Is a 2% offset (92% vs. 94%) sufficient or desirable?

Perhaps looking at the data another way may be helpful. Both STOP-ROP

(Figure 4) and BOOST (Figure 1) presented smoothed frequency distributions that showed not only clear offsets in curves, but also the modes of the two curves occurring within the target ranges. A similar set of curves using the current SUPPORT data might reassure us and the DSMB that good separation has been attained. (Or it might alarm us. I'm worried that this will be the case, as the median value for the 85-89% group falls outside the target range.) I've tried to estimate such a curve for the SUPPORT data, but couldn't do it without point-by-point values.

3. The approach of tightening the compliance to targets is obviously the way to proceed forward. The proposed methods sound fine. I'd be more comfortable if there some plan to reassess compliance relatively shortly with another analysis. A couple of suggestions that may help with compliance, both of which fall solidly into other people's baliwicks:

a. The histograms used in STOP-ROP were very powerful images that clearly and simply showed degree of compliance with targets. I couldn't find anyone who remembered specifically, but I think the nurses in our unit did not use them during STOP-ROP. I do think, however, that they would be very useful tools for the nurses to have, as you have suggested.

b. There was considerable inter-center variability in the data you sent. Benchmarking with the most successful centers might be useful.

Since I'm not sure Dale will be voting for our center, I'll cast a vote. If Dale votes, I consider myself over-ruled.

I would favor sending on the response to the DSMB, provided it included some more specific comparison to what other studies of differing saturation targets have been able to achieve. If we have been unable to get the sort of separation achieved by others, the modifications to improve compliance will be even more important. I would also favor proposing a repeat evaluation after the next N (choose your favorite N) subjects to assess any improvement in compliance.

Neil, thanks for the incredible amount of work you and the folks at RTI have done in a very short time.

Carl

<<Response to DSMC Steering Nov 30 05.doc>>

In response to the comments and concerns of the DSMC, the SUPPORT committee held a conference call Monday Nov 28th at 10:00 to 1130AM to prepare a response.

- The DSMC made the following 2 comments in their letter regarding the SUPPORT trial. This was generated after they reviewed the oximeter data, which was corrected back to actual SpO2 values from the altered values displayed at the bedside:

1. There is a significant safety and exposure issue for the infants in the high saturation treatment group because an unacceptably high proportion of time was spent by these study subjects in the >95% range

2. There is a futility concern for this arm of the trial in that there does not appear to be substantial separation between the two high and low saturation treatment groups, and the babies are not being kept in the target range the appropriate amount of time in order to meaningfully test the oxygen saturation intervention as originally designed.

Based on these two issues, the consensus of the Committee was to recommend stopping the oxygen saturation arms of the SUPPORT trial due to safety and futility concerns.

We have responded to each of these concerns and our responses are detailed below

Response to Issue Number 1

We appreciate the concern expressed by the DSMC regarding a potential safety issue secondary to durations of SpO2 values > 95%. To date there are no prospective data which define the SpO2s experienced by the ELBW infant from birth as part of usual clinical care. Because no published studies have evaluated the effects of different target SpO2 ranges on important outcomes, this was one of the principle reasons for the design and conduct of the SUPPORT trial. A number of studies have evaluated different alarm limits, but have not reported the actual durations of SpO2 in the various ranges. Nghiem et al in a PAS abstract this year reported that nurses caring for ELBW infants believe that an acceptable oxygen saturation range should include higher upper limits than specified by current policy (Nghiem et al, Nursing Opinions and Practices of Oxygenation in Prematures: The NOPOP Study PAS #3415, 2005). The study by Hagadorn reported as a late breaker at the PAS this year (Hagadorn et al, Actual vs Intended Pulse Oxygen Saturation (SpO2) in Infants <28 Weeks Gestation. PAS 2005, Attached) did report on the experience of monitoring the actual SpO2 for 72 hours in the first 4 weeks of life in 72 ELBW infants. They reported that the "lower limits of intended ranges at study centers varied between 83-92%, upper limits 92-98%. Infants were monitored for a median of 70 hours (25th-75th percentiles 67-71 hr) during each week. Overall median SpO2 for infants on supplemental O2 during the first 4 weeks was 95% (25th-75th percentiles 91-97%; range of study center medians 91-96%). Centers ranged between 16-71% compliance with their individual intended SpO2 range. Most noncompliance was above intended range." In comparing the data evaluated to date by the DSMC, it is of interest that the mean SpO2 in the 2.Oximeter arms is 90% and 92%, with

medians of 92% and 94%, all of which are below that reported by Hagadorn et al (median=95). The 2 other relevant trials, STOP-ROP and BOOST, both enrolled infants at about 32 weeks PCA, and maintained 2 levels of SpO2, 89% to 94% and 91-94% versus 95% to 98% and 96% to 99%, by administration of oxygen. These studies achieved reasonable separation, but did demonstrate substantial overlap of the intended ranges. It is important to note that these studies were testing two ranges both of which were higher than the lower range of the SUPPORT trial (85% to 89%) and were treating infants who, for the most part, had recovered from their acute disease. In the BOOST trial 70% of the enrolled infants were < 28 weeks of age at birth (all of SUPPORT is < 28 weeks), 32 weeks postmenstrual age (PMA), and required oxygen at enrollment (Askie et al, New England Journal of Medicine. 2003; 349(10):959-967). The STOP-ROP trial enrolled infants with pre-threshold ROP at a PMA of 35.4 + 2.5 weeks of age (Phelps et al, Pediatrics. 2000; 105(2):295-310). These trials then gave the higher SpO2 range infants additional oxygen to increase their SpO2 to the desired range. STOP-ROP reported that the infants in the high range had an SpO2 > 95% for > 97% of the monitored time. These studies found an overall increase in pulmonary morbidity in the higher SpO2 range infants.

Examination of oximeter data from one if the NRN sites (Case Western, Walsh et al) obtained for an ongoing study evaluating infants similar to those enrolled in SUPPORT, and managed with conventional oximeters revealed that for the 9 infants for whom results were available that the percentage of time with and SpO2 > 95% was > 50%.

The oximetry algorithm that was designed for the SUPPORT trial is such that re-conversion of the altered oximeter values does not result in a discrete SpO2 number for every displayed value. SpO2 values, of 93%, 94% 95% and 96% will all be reconverted to a single value in one arm, while 84%, 85%, 86% and 87% will be reconverted to a single value in the other arm. This is a result of having the displayed values return to non-skewed SpO2 values at < 84% and > 96%, a safety design felt to be important by all involved in this trial (See Attached file USCD1). Thus the percentages reported to the DSMC for some of the ranges that include these values were not an accurate representation of the true values. However all values > 96% and < 84% are actual and do not require any conversion.

Percent of time of spent at SpO2 < 84% and > 96%
(RTI, Nov 29, 2005, 14:00 Hrs)

Range	High target (91-95)	Low target (85-89)
< 84%	8.51	16.62
> 96%	22.69	13.60

In the current SUPPORT study, an initial analyses utilizing only unaltered SpO2 values as shown above , ie those below 84% and above 96% have shown that one arm had an SpO2 > 96% for 13.6% versus 22.69% of the time for the comparison arm, and the durations of an SpO2 < 84% was also different at

16.62% versus 8.51%. The previously reported value of 36% duration of an SpO2 > 95% for one group represented an artifact of the conversion algorithm as described above. The values for SpO2s > 96% using unaltered data suggests that the SUPPORT trial to date has, if anything, reduced the duration of hyperoxia.

In addition, using these values which represent actual SpO2 values, we can state that the infants in this trial are spending approximately 70% of the time with a true SpO2 value between 84% and 96%. We believe that this is information is very encouraging, and suggests that if we are able to further improve adherence to the target ranges that we will achieve an adequate separation between the groups.

As part of the SUPPORT trial, we collect information about inhaled oxygen concentration 3 times a day for the first 14 days and daily thereafter. We believe that a more frequent documentation of inhaled oxygen will allow us to determine the actual duration of oxygen exposure. At the present an infant is considered to be receiving supplemental oxygen if he/she requires oxygen for greater than 2 hours. This results in infants being categorized as receiving supplemental oxygen for significant periods when they are actually in room air. This would result in durations of SpO2 greater than 95% that were felt to be modifiable and reported as such when in fact there is no effective treatment for such elevated SpO2s. In addition, we do not know if such SpO2s on room air are associated with any morbidity. From the SUPPORT study data analyses to date we know that infants in room air have SpO2s > 95% for 46% to 69% of the time.

In view of this design, we would suggest that all future analyses evaluate the ranges of <84% and >96% as those ranges that are considered to be low and high.

We believe that the SUPPORT trial will actually define the periods of time that ELBW infants spend with different ranges of SpO2, and that it is essential to collect this information. In addition, as our findings indicate a lower true percent of the time at SpO2 values >95%, and lower median SpO2 values than has previously been reported, we are in fact, reducing the time with high SpO2 values compared to usual care. The SUPPORT trial carefully evaluates risks, and we will be evaluating group differences for all important short and long term outcomes.

The SUPPORT trial methodology actively encourages all caretakers to keep SpO2 < 96% by having alarm limits set at 85% to 95%. These limits were utilized because it was felt that these represented current practice. The oximetry algorithms were designed to keep infants in the narrower target range of 88% to 92% with the realization that setting alarm limits at these values would severely increase the frequency of the alarms sounding. Nevertheless, our results to date suggest that we have decreased the expected percent of time > 95%, and in one group the value of 14% may be as low as is achievable in an actual clinical environment.

We believe that the SUPPORT study will define the durations of high and low SpO2 and will be able to determine if there is a threshold duration of either value that is associated with altered outcomes, and for this reason alone, the

SUPPORT trial will be very valuable. All of the procedures outlined below in response to your second concern will also allow us to further increase the percentage of time that the infants are in the maximally altered SpO2 ranges which we believe will further increase separation of these groups.

Response to Issue Number 2

There is concern that we have not achieved adequate separation by the current oximeters and study personnel. Reviewing the newest analyses available as described above, there are differences in the durations of low and high SpO2s between the 2 oximeter groups. In addition, a careful analysis of the most recent converted values demonstrates that the cumulative time spent with an SpO2 of 90% or less is 24.3% versus 43%, for the 2 oximeter groups, supporting the ability of the altered oximeters to produce differential SpO2 exposures. We do acknowledge that it would desirable to increase the percentage of time in the narrower target range and towards this end would propose the following changes to SUPPORT:

1. We will require documentation that the alarm limits are set and functional as per protocol every 4-6 hours. We have found that in some units the high alarms are being defeated, and thus believe that such documentation will greatly assist in decreasing the actual time that the SpO2 is > 96%. This task will be assigned to the respiratory therapists, and this procedure is already being done in many NRN units.

2. We will immediately initiate a change in our data collection for FiO2. We will change the data form to indicate that the infant was either in oxygen for the entire 24 hours, and if not, will check off the actual hours of oxygen exposure, and we will continue with this from of data collection for the entire time that the infant is receiving oxygen. In the current protocol we collect such information 3 times a day for the first 14 days only and then daily thereafter. We believe that more frequent documentation will allow us to determine the actual time that an infant is in room air. At the present the infant is considered in oxygen if he/she requires oxygen for greater than intermittent use. This results in infants being categorized in oxygen for significant periods when they are in room air. While in room air, we cannot manipulate the SpO2, and thus knowledge of the true time in oxygen will produce a more accurate representation of oximetry results that are subject to care interventions.

Comment [d1]: "form"

Comment [d2]: add "and extended"

3. We will initiate further training and in-service at all the sites to stress the importance of keeping the SpO2 alarm functional and at the limits of 85% and 95%. In the past these were guidelines, and we will now change the study manual and protocol to indicate these limits are now set by protocol and that violations will be documented. We will encourage all caretakers to aim for an SpO2 value of 90% and make every effort to educate caretakers to make smaller

adjustments in FiO2 and ensure that the infant is maintained between the 87% to 93%, the range with the maximal separation of the study oximeters. We will further facilitate the use of the 2 hour and 12 hour histograms showing the infants' actual ranges to provide feedback to the caretakers regarding the percentage of time in the target ranges.

4. We will develop guidelines for managing desaturations such that the increase in oxygen is proportional to the desaturation. We would hope that such changes – ie increasing the FiO2 in steps of 5% as opposed to much larger increases will decrease the resultant overshoots creating the high SpO2 values. This will be included in the revised manual of operations.

5. We will place bedside cards to indicate the target range.

6. We will initiate compliance monitoring visits coordinated by RTI to visit random sites. These visits had been planned, but had not yet been initiated. The teams will consist of a member of RTI and a study coordinator, and they will review the adherence to the protocol and any other relevant issues.

We thank the DSMC for their thoughtful concerns. We trust that our plans to move forward with the SUPPORT trial are acceptable to the DSMC. We are anxious to initiate the above changes, seek IRB approvals and re-activate this trial.

---

Thanks for this excellent work Neil. I spent some time making editorial changes that I believe will facilitate the DSMCs review of this comprehensive and complex document.
(I guess I am still in book editor mode!) Hope this helps.
Michele

Subject: Response to DSMC Steering Nov 30 05

HI,
Attached is the final response to the DSMC as discussed on the phone this morning. Please review this and let me know by tomorrow (December 1) evening if this is acceptable to you and your site.
A special thanks to Neil and RTI (Marie and Abhik) for all the time and effort that has been put into this project!!
Rose
<<Response to DSMC Steering Nov 30 05.doc>>

In response to the comments and concerns of the DSMC, the SUPPORT committee held a conference call Monday Nov 28th at 10:00 to 1130AM to prepare a response.

- The DSMC made the following 2 comments in their letter regarding the SUPPORT trial. This was generated after they reviewed the oximeter data, which was corrected back to actual SpO2 values from the altered values displayed at the bedside:

1. There is a significant safety and exposure issue for the infants in the high saturation treatment group because an unacceptably high proportion of time was spent by these study subjects in the >95% range

2. There is a futility concern for this arm of the trial in that there does not appear to be substantial separation between the two high and low saturation treatment groups, and the babies are not being kept in the target range the appropriate amount of time in order to meaningfully test the oxygen saturation intervention as originally designed.

Based on these two issues, the consensus of the Committee was to recommend stopping the oxygen saturation arms of the SUPPORT trial due to safety and futility concerns.

We have responded to each of these concerns and our responses are detailed below

Response to Issue Number 1

We appreciate the concern expressed by the DSMC regarding a potential safety issue secondary to durations of SpO2 values > 95%.

1. To date there are no prospective data which define the SpO2s experienced by the ELBW infant from birth as part of usual clinical care. Because no published studies have evaluated the effects of different target SpO2 ranges on important outcomes, this was one of the principle reasons for the design and conduct of the SUPPORT trial.

2. A number of studies have evaluated different alarm limits, but have not reported the actual durations of SpO2 in the various ranges. Nghiem et al in a PAS abstract this year reported that nurses caring for ELBW infants believe that an acceptable oxygen saturation range should include higher upper limits than specified by current policy (Nghiem et al, Nursing Opinions and Practices of Oxygenation in Prematures: The NOPOP Study PAS #3415, 2005). The study by Hagadorn reported as a late breaker at the PAS this year (Hagadorn et al, Actual vs Intended Pulse Oxygen Saturation (SpO2) in Infants <28 Weeks Gestation. PAS 2005, Attached) did report on the experience of monitoring the actual SpO2 for 72 hours in the first 4 weeks of life in 72 ELBW infants. They reported that the "lower limits of intended ranges at study centers varied between 83-92%, upper limits 92-98%. Infants were monitored for a median of 70 hours (25th-75th percentiles 67-71 hr) during each week. Overall median SpO2 for infants on supplemental O2 during the first 4 weeks was 95% (25th-75th percentiles 91-97%; range of study center medians 91-96%). Centers ranged between 16-71% compliance with their individual intended SpO2 range. Most noncompliance was above intended range." In comparing the SUPPORT data

Formatted

Formatted

Formatted

evaluated to date by the DSMC, it is of interest that the mean SpO2 in the 2 Oximeter arms is 90% and 92%, with medians of 92% and 94%, all of which are below that reported by Hagadorn et al (median=95).

The 2 other relevant trials, STOP-ROP and BOOST, both enrolled infants at about 32 weeks PCA, and maintained 2 levels of SpO2, 89% to 94% and 91-94% versus 95% to 98% and 96% to 99%, by administration of oxygen. These studies achieved reasonable separation, but did demonstrate substantial overlap of the intended ranges. It is important to note that these studies were testing two ranges both of which were higher than the lower range of the SUPPORT trial (85% to 89%) and were treating infants who, for the most part, had recovered from their acute disease. In the BOOST trial 70% of the enrolled infants were < 28 weeks of age at birth (all of SUPPORT is < 28 weeks), 32 weeks postmenstrual age (PMA), and required oxygen at enrollment (Askie et al, New England Journal of Medicine. 2003; 349(10):959-967). The STOP-ROP trial enrolled infants with pre-threshold ROP at a PMA of 35.4 + 2.5 weeks of age (Phelps et al, Pediatrics. 2000; 105(2):295-310). These trials then gave the higher SpO2 range infants additional oxygen to increase their SpO2 to the desired range. STOP-ROP reported that the infants in the high range had an SpO2 > 95% for > 97% of the monitored time. These studies found an overall increase in pulmonary morbidity in the higher SpO2 range infants.

Examination of oximeter data from one ~~if~~ of the NRN sites (Case Western, Walsh et al) obtained for an ongoing study evaluating infants similar to those enrolled in SUPPORT, and managed with conventional oximeters revealed that for the 9 infants for whom results were available that the percentage of time with ~~and~~ SpO2 > 95% was > 50%.

3. Impact of SUPPORT oximeters algorithm on sat values:

———The oximetry algorithm that was designed for the SUPPORT trial is such that re-conversion of the altered oximeter values does not result in a discrete SpO2 number for every displayed value. SpO2 values, of 93%, 94% 95% and 96% will all be reconverted to a single value in one arm, while 84%, 85%, 86% and 87% will be reconverted to a single value in the other arm. This is a result of having the displayed values return to non-skewed SpO2 values at < 84% and > 96%, a safety design felt to be important by all involved in this trial (See Attached file USCD1). Thus the percentages reported to the DSMC for some of the ranges that include these values were not an accurate representation of the true values. However all values > 96% and < 84% are actual and do not require any conversion.

Percent of time of spent at SpO2 < 84% and > 96%
(RTI, Nov 29, 2005, 14:00 Hrs)

Range	High target (91-95)	Low target (85-89)
< 84%	8.51	16.62
> 96%	22.69	13.60

In the current SUPPORT study, an initial analyseis utilizing only unaltered SpO2 values, ~~as shown above , ie~~ those below 84% and above 96%, have shown that one arm had an SpO2 > 96% for 13.6% versus 22.69% of the time for the comparison arm, and the durations of an SpO2 < 84% was also different at 16.62% versus 8.51%. The previously reported value of 36% duration of an SpO2 > 95% for one group represented an artifact of the conversion algorithm as described above. **The values for SpO2s > 96% using ~~unaltered~~ uncorrected data suggests that the SUPPORT trial to date has, if anything, reduced the duration of hyperoxia~~.~~. compared to that experienced by comparable neonates outside the trial,**

In addition, analyses using ~~these values which represent~~ only actual SpO2 values, ~~we can state that the~~demonstrate that infants in this trial are spending approximately 70% of the time with a true SpO2 value between 84% and 96%. We believe that this is information is very encouraging, and suggests that if we are able to further improve adherence to the target ranges that we will achieve an adequate separation between the groups.

4. Impact of inclusion of data from periods in room air on saturation distributions:

As part of the SUPPORT trial, we collect information about inhaled oxygen concentration 3 times a day for the first 14 days and daily thereafter. We believe that a more frequent documentation of inhaled oxygen will allow us to determine the actual duration of oxygen exposure. At the present an infant is considered to be receiving supplemental oxygen if he/she requires oxygen for greater than 2 hours. This results in infants being categorized as receiving supplemental oxygen for significant periods when they are actually in room air. This would result in durations of SpO2 greater than 95% that were felt to be modifiable and reported as such when in fact there is no effective treatment for such elevated SpO2s. In addition, we do not know if such SpO2s on room air are associated with any morbidity. From the SUPPORT study data analyses to date we know that infants in room air have SpO2s > 95% for 46% to 69% of the time.

In view of this design, we would suggest that all future analyses for the DSMC evaluate the saturation ranges of <84% and >96% in children on oxygen therapy as those ranges that are outside the target range. ~~considered to be low and high.~~

We believe that the SUPPORT trial will actually define the periods of time that ELBW infants spend with different ranges of SpO2, and that it is essential to collect this information. In addition, as our findings indicate a lower true percent of the time at SpO2 values >95%, and lower median SpO2 values than has previously been reported, we are in fact, reducing the time with high SpO2 values compared to usual care. The SUPPORT trial carefully evaluates risks, and we will be evaluating group differences for all important short and long term outcomes.

The SUPPORT trial methodology actively encourages all caretakers to keep SpO2 < 96% by having alarm limits set at 85% to 95%. These limits were utilized because it was felt that these represented current practice. The oximetry algorithms were designed to keep infants in the narrower target range of 88% to 92% with the realization that setting alarm limits at these values would severely

increase the frequency of the alarms sounding. Nevertheless, our results to date suggest that we have decreased the expected percent of time > 95%, and in one group the value of 14% may be as low as is achievable in an actual clinical environment.

We believe that the SUPPORT study will define the durations of high and low SpO2 and will be able to determine if there is a threshold duration of either value that is associated with altered outcomes, and for this reason alone, the SUPPORT trial will be very valuable. All of the procedures outlined below in response to your second concern will also allow us to further increase the percentage of time that the infants are in the maximally altered SpO2 ranges which we believe will further increase separation of these groups.

Response to Issue Number 2

There is concern that we have not achieved adequate separation by the current oximeters and study personnel.

1. As described above, ~~Reviewing~~ the newest analyses ~~available as described above, there are~~ show differences in the durations of low and high SpO2s between the 2 oximeter groups. ~~In addition, A~~a careful analysis of the most recent converted values demonstrates that the cumulative time spent with an SpO2 of 90% or less is 24.3% versus 43%, for the 2 oximeter groups, supporting the ability of the altered oximeters to produce differential SpO2 exposures.

2. We do acknowledge that it would desirable to increase the percentage of time in the narrower target range and towards this end would propose the following changes to SUPPORT:

A~~1~~. We will require **documentation that the alarm limits are set and functional as per protocol every 4-6 hours**. We have found that in some units the high alarms are being defeated, and thus believe that such documentation will greatly assist in decreasing the actual time that the SpO2 is > 96%. This task will be assigned to the respiratory therapists, and this procedure is already being done in ~~many~~ some NRN units.

B~~2~~. We will immediately initiate a **change in our data collection for FiO2 to ensure that DSMC reports more accurately reflect saturations measured while on oxygen therapy and exclude saturations of infants in room air**. We will change the data form to indicate that the infant was either in oxygen for the entire 24 hours, and if not, will check off the actual hours of oxygen exposure, and we will continue with this from of data collection for the entire time that the infant is receiving oxygen. In the current protocol we collect such information 3 times a day for the first 14 days only and then daily thereafter. We believe that more frequent documentation will allow us to determine the actual time that an infant is in room air. At the present the infant is considered in oxygen if he/she requires oxygen for greater than intermittent use. This results in infants being

Formatted

Formatted

categorized in oxygen for significant periods when they are in room air. While in room air, we cannot manipulate the SpO2, and thus knowledge of the true time in oxygen will produce a more accurate representation of oximetry results that are subject to care interventions.

3C. We will initiate **further training and in-service at all the sites to stress the importance of keeping the SpO2 alarm functional and at the limits of 85% and 95%.** In the past these were guidelines, and we will now change the study manual and protocol to indicate these limits are now set by protocol and that violations will be documented. We will encourage all caretakers to aim for an SpO2 value of 90% and make every effort to educate caretakers to make smaller adjustments in FiO2 and ensure that the infant is maintained between the 87% to 93%, the range with the maximal separation of the study oximeters. We will further facilitate the use of the 2 hour and 12 hour histograms showing the infants' actual ranges to provide feedback to the caretakers regarding the percentage of time in the target ranges.

Formatted

D.4. We will **develop guidelines for managing desaturations such that the increase in oxygen is proportional to the severity of the desaturation**. More modulated increases in oxygen during these desaturation events will minimize overshoot and the potential of high SpO2 values. ~~We would hope that such changes – ie increasing the FiO2 in steps of 5% as opposed to much larger increases will decrease the resultant overshoots creating the high SpO2 values~~. This will be included in the revised manual of operations.

The PI's of the SUPPORT trial have developed a written response which includes additional data analyses that are likely to support resumption of the trial. I had asked RTI to get the DSMC together on a phone call – it is becoming a problem with the upcoming holidays – I am under the impression that we need approval from each and every member, correct? Let me know
Thanks

---

Hi Rose
Here is the current version with the changes from the call. I re-added Michele's data as it is current and reflects NRN practice. Your call if you feel this part should stay.
I have attached all the relevant material that we would want to send to the DSMC.
I will relook at the RTI data after the run is complete. If this results in major changes I will discuss with you.
Many thanks
Neil

Oxygen-Saturation Targets and Outcomes in Extremely Preterm Infants

Lisa Maree Askie, Ph.D., M.P.H., David John Henderson-Smart, Ph.D., M.B., B.S., Les Irwig, Ph.D., M.B., B.Ch., and Judy Margaret Simpson, Ph.D.

ABSTRACT

BACKGROUND

Physiological studies have shown that chronic hypoxemia may occur in preterm infants who require supplemental oxygen for extended periods and that this hypoxemia may contribute to poor growth and development. Anecdotal reports and uncontrolled observational studies have suggested that a higher oxygen-saturation range may be beneficial in terms of growth and development.

METHODS

We conducted a multicenter, double-blind, randomized, controlled trial involving 358 infants born at less than 30 weeks of gestation who remained dependent on supplemental oxygen at 32 weeks of postmenstrual age. They were randomly assigned to a target functional oxygen-saturation range of either 91 to 94 percent (standard-saturation group) or 95 to 98 percent (high-saturation group); this target was maintained for the duration of supplemental-oxygen therapy. The primary outcomes were growth and neurodevelopmental measures at a corrected age of 12 months.

RESULTS

There were no significant differences between the groups in weight, length, or head circumference at a corrected age of 12 months. The frequency of major developmental abnormalities also did not differ significantly between the standard-saturation group and the high-saturation group (24 percent and 23 percent, respectively, P=0.85). There were six deaths due to pulmonary causes in the high-saturation group and one such death in the standard-saturation group (P=0.12). The high-saturation group received oxygen for a longer period after randomization (median, 40 days vs. 18 days; P<0.001) and had a significantly higher rate of dependence on supplemental oxygen at 36 weeks of postmenstrual age and a significantly higher frequency of home-based oxygen therapy.

CONCLUSIONS

Targeting a higher oxygen-saturation range in extremely preterm infants who were dependent on supplemental oxygen conferred no significant benefit with respect to growth and development and resulted in an increased burden on health services.

N Engl J Med 2003;349:959-67.

Improved survival of extremely preterm infants[1] has been associated with an increase in the incidence of chronic lung disease of infancy,[2] currently defined by a continued dependence on supplemental oxygen at 36 weeks of postmenstrual age.[3,4] This increased incidence has become a major clinical challenge, since chronic lung disease has serious health consequences, including poor growth,[5,6] neurologic impairment,[5,7] and pulmonary sequelae.[5,8] These and other factors may account for the higher reported health care costs for these infants than for infants who do not have chronic lung disease.[9]

Physiological studies have shown that infants with chronic lung disease (also known as bronchopulmonary dysplasia) have higher rates of oxygen consumption than infants without chronic lung disease,[10] as well as lower base-line oxygen-saturation levels, leading to more frequent episodes of desaturation.[11,12] In addition, observational studies have suggested that preterm infants who receive greater levels of oxygen supplementation, with either a longer duration of treatment or a higher target blood oxygen level, have improvements in sleep patterns,[13,14] growth, and neurodevelopmental outcomes.[15,16] Because of the uncontrolled nature of the studies, it is not known whether these associations are causal.

A policy of routine targeting of higher oxygen-saturation levels in preterm infants might result in some substantial burdens for the health care system and for parents, by increasing the duration of oxygen therapy in the hospital and the frequency of the need for home-based oxygen therapy. Despite some potential costs and the lack of evidence of long-term benefits, such policies are increasingly being implemented in clinical practice.[17,18] Data from randomized, controlled trials are lacking,[19,20] and the question of the most appropriate oxygen-saturation levels for preterm infants who require supplemental oxygen remains controversial.[21-23]

We conducted the randomized, multicenter Benefits of Oxygen Saturation Targeting (BOOST) trial to determine whether maintaining the oxygen saturation at a level higher than the standard range in extremely preterm infants with a long-term dependence on supplemental oxygen improves growth and neurodevelopmental outcomes. Secondary aims were to determine whether the higher oxygen-saturation levels had other beneficial or adverse physical or psychosocial effects on infants or parents.

METHODS

CRITERIA FOR ELIGIBILITY

Infants born at less than 30 weeks of gestational age (determined on the basis of the first day of the mother's last menstrual period, prenatal ultrasonography, or both or, if these data were not available, postnatal clinical assessment) who remained dependent on supplemental oxygen (delivered by any method and at any level) at 32 weeks of postmenstrual age were eligible for enrollment. Dependence on supplemental oxygen at 32 weeks of postmenstrual age, rather than 36 weeks, was used as a criterion for inclusion because it was current clinical practice to choose between the standard target range for oxygen saturation and a higher target range at this point in the infant's life. Criteria for exclusion before randomization included major congenital abnormalities, major surgery or a severe intracranial disorder diagnosed before 32 weeks of postmenstrual age, and a multiple birth in which three or more infants were eligible. The protocol allowed for infants from multiple gestations resulting in two eligible infants to be assigned to the same treatment.

The institutional ethics committees of the eight tertiary perinatal enrollment centers participating in the study approved the trial protocol, and written, informed consent was obtained from a parent or guardian of each eligible infant. Infants were enrolled between September 1996 and September 2000.

INTERVENTION AND BLINDING

Infants were randomly assigned to a target oxygen-saturation range of either 91 to 94 percent (standard-saturation group) or 95 to 98 percent (high-saturation group), as measured with a pulse oximeter (model N-3000, Nellcor) whose algorithm assesses functional oxygen saturation.[24] Randomization was stratified with the use of a dynamic balancing method[25] to ensure a balance of treatment-group assignments within each stratum defined according to hospital, singleton or multiple birth, and gestational age (22 to 27 weeks or 28 to 29 weeks). Central telephone randomization ensured concealment of the treatment-group assignments.

To make sure that the treatment-group assignments were not revealed, the infants who underwent randomization were assigned a specific study oximeter, which after the calculation of the infant's

oxygen-saturation level in the usual manner, was adjusted to display a value 2 percent higher than the actual saturation in infants in the standard-saturation group or 2 percent lower than the actual saturation in infants in the high-saturation group. Staff members and parents were then asked to target the range of 93 to 96 percent for the infant's oxygen saturation, so that they remained unaware of the actual ranges being targeted. Caregivers were aware that they were using adjusted oximeters and that they were participating in a trial, but they were not aware of the offset level of the individual oximeter. Double-blind targeting of the assigned saturation range was maintained for the duration of the infant's oxygen therapy either in the hospital (in both the enrollment center and other hospitals if necessary) or at home.

Dependence on supplemental oxygen was defined by the continuing need for oxygen therapy in order to maintain the double-blind target oxygen-saturation range of 93 to 96 percent, as measured by the assigned study oximeter. The frequency of monitoring of the saturation (continuous or intermittent), the settings for limits that were to trigger alarms, and the criteria for titrating the amount of ambient oxygen delivered or for ceasing delivery were determined by the attending clinicians and were not specified by the trial protocol.

ADHERENCE TO THE PROTOCOL

Compliance with the double-blind target oxygen-saturation range of 93 to 96 percent was assessed with the use of twice-weekly downloading of each infant's oxygen-saturation data, and a report on the distribution of the double-blind saturation levels was placed in the case notes. Clinicians and parents were allowed to violate the protocol either temporarily or permanently if they believed that the infant's condition warranted high-saturation oxygen therapy — for instance, because of serious intercurrent illness, as treatment for prethreshold retinopathy of prematurity, or during surgery.

PRIMARY OUTCOMES

The primary outcomes assessed at a corrected age of one year (the chronologic age plus the number of weeks of prematurity) included growth, in terms of the mean weight, the mean length, the mean head circumference, and the proportion of infants with a weight below the 10th percentile,[26] and the presence of a major developmental abnormality, defined as blindness, cerebral palsy, or a score on the revised Griffiths Mental Developmental Scales that was more than 2 SD below the mean (general quotient, <77).[27] Blindness was defined as a visual acuity in both eyes of less than 6/60.[28] Cerebral palsy was diagnosed if the child had nonprogressive motor impairment characterized by abnormal muscle tone and a decreased range or decreased control of movements, accompanied by neurologic signs.[29]

SECONDARY OUTCOMES

The secondary outcomes included the effect of the treatment-group assignment on the duration of oxygen therapy, the duration of assisted ventilation and of the hospital stay, and the frequency of home-based oxygen therapy. Parental stress and parent–infant interaction were assessed by means of validated scales (the Edinburgh Postnatal Depression Scale,[30] the Infant Temperament Questionnaire,[31] the Toddler Temperament Scale,[32] the Parenting Stress Index, Short Form,[33] and the Impact-on-Family Scale[34]). Retinopathy of prematurity was assessed by routine ophthalmic examinations at two-week intervals from enrollment until the resolution of retinopathy, with grading according to the International Classification of Retinopathy of Prematurity.[35] Reports by the parents on the use of health services and rehospitalizations during the first year of life were obtained through quarterly telephone contact by the research nurses, and rehospitalizations were confirmed through a review of the medical records. Causes of death were classified according to the codes of the *International Classification of Diseases, Ninth Revision*,[36] and confirmed on the basis of the hospital discharge summary, a postmortem examination report, a coroner's report, or a death certificate.

STATISTICAL ANALYSIS

All data analyses were performed according to the intention-to-treat principle. For continuous data, the treatment effect was calculated by subtracting the value for the standard-saturation group from the value for the high-saturation group, with results for normally distributed data presented as means ±SD and results for non–normally distributed data presented as medians with interquartile ranges. Differences between the two groups were assessed with the use of Student's t-test or the Mann–Whitney U test and are expressed as mean or median differences, respectively, with 95 percent confidence in-

tervals. For categorical data, the chi-square test was used, and the treatment effects are expressed as relative risks in the high-saturation group as compared with the standard-saturation group, with 95 percent confidence intervals. For analyses involving small numbers of events, Fisher's exact test was used, and exact confidence intervals were calculated for odds ratios, as approximate relative risks. All P values are two-sided and have not been adjusted for multiple testing or for correlation between the outcomes in siblings, since only 25 pairs of siblings were included (a total of 50 infants), representing 14 percent of the infants, and they were distributed approximately equally between the two groups.

The required sample size was calculated to ensure detection of clinically important effects on the primary outcomes: a reduction from the base-line estimate of 47 percent to 30 percent in the proportion of infants with a weight below the 10th percentile at a corrected age of 12 months, and a reduction in the frequency of major developmental abnormalities from 23 percent to 12 percent.[37] To achieve 80 percent power with a two-sided alpha level of 0.05 and a 1:1 ratio of infants in the two groups, approximately 150 infants were required in each group.

Table 1. Base-Line Characteristics of the Infants and Mothers.*

Characteristic	Standard-Saturation Group (N=178)	High-Saturation Group (N=180)
Birth weight — g	918±229	916±231
Gestational age at birth — wk	26.6±1.7	26.5±1.6
<28 Wk of gestation at birth — no. (%)	124 (70)	132 (73)
Male sex — no. (%)	92 (52)	97 (54)
Singleton birth — no. (%)	133 (75)	129 (72)
Born in tertiary care center — no. (%)	163 (92)	172 (96)
Surfactant treatment — no. (%)	138 (78)	137 (76)
Patent ductus arteriosus — no. (%)	94 (53)	91 (51)
Total duration of parenteral nutrition — days		
Median	13.5	13.0
Interquartile range	9.0–20.0	9.0–20.0
Antenatal corticosteroids — no. (%)	148 (83)	149 (83)
Score on the Edinburgh Postnatal Depression Scale†	10.7±5.7	10.0±5.3
Maternal educational level >high school — no. (%)	60 (34)	64 (36)
Maternal occupation score‡	4.5±1.4	4.6±1.3

* Plus–minus values are means ±SD.
† Scores range from 0 to 30, with higher scores indicating greater severity of depressive symptoms.[30]
‡ Data are the scores on Daniel's occupation scale[38]; scores range from 1 to 7, with lower scores indicating higher occupational prestige.

An independent safety monitoring committee, comprising a pediatric ophthalmologist, a neonatologist, and a pediatric respiratory physician–epidemiologist, all of whom were unaware of the treatment-group assignments, assessed adverse outcomes, including death, at five prespecified time points. The stopping rules were never breached.

RESULTS

PARTICIPANTS

Of the 703 infants who were eligible during the enrollment period, 158 met the criteria for exclusion before randomization. A total of 187 of the remaining 545 eligible infants were not enrolled (consent was not obtained for 122 infants, and the parent or guardian was not approached for 65 infants). There were 333 infants who underwent individual randomization, and an additional 25 eligible multiples were assigned to the same group as their sibling, for a total of 358 individual infants receiving one of the two treatments for whom outcomes were analyzed. A total of 178 infants were assigned to the standard-saturation group (target oxygen saturation, 91 to 94 percent) and 180 to the high-saturation group (target oxygen saturation, 95 to 98 percent). The two groups were well balanced in terms of the base-line characteristics of the infants and the mothers (Table 1). The intervention continued for a median of 17.5 days (interquartile range, 7.0 to 41.0) in the standard-saturation group and 40.0 days (interquartile range, 20.5 to 73.0) in the high-saturation group ($P<0.001$).

ADHERENCE TO THE PROTOCOL

Figure 1 shows the two distributions of the actual saturation levels. The median for each group was within the desired target range. Permitted protocol violations for open targeting of the oxygen saturation occurred relatively infrequently (on 54 occasions), generally for short periods (median, 7 days; interquartile range, 3 to 17), and the occurrences were equally distributed between the two groups.

PRIMARY OUTCOMES

The rate of ascertainment of primary outcomes was 93 percent in the standard-saturation group (165 of 178 infants) and 93 percent in the high-saturation group (168 of 180 infants). The median age at the assessment of the primary outcomes did not differ between the two groups (a corrected age of 12.1 months [interquartile range, 11.8 to 12.7] in the standard-saturation group and a corrected age of

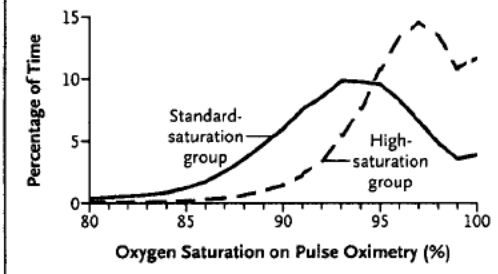

Figure 1. Smoothed Frequency Distribution of Actual Oxygen-Saturation Values on Pulse Oximetry during Oxygen Therapy after Randomization.

The saturation values were sampled every 10 seconds during intermittent downloads performed approximately twice weekly and lasting 8 to 24 hours each. The median oxygen saturation was 93 percent in the standard-saturation group (interquartile range, 90 to 96) and 97 percent in the high-saturation group (interquartile range, 94 to 98).

12.2 months [interquartile range, 11.9 to 12.9] in the high-saturation group).

There were no significant differences between the two groups in the mean weight, length, or head circumference at 38 weeks of postmenstrual age (Table 2). In addition, at a corrected age of 12 months, there were no significant differences in the measurements of weight, length, or head circumference; the proportion of infants who were small for their age; or the proportion of infants with a major developmental abnormality (Table 2). Our data also showed no significant difference between the two groups in the frequency of developmental scores that were more than 1 SD but less than 2 SD below the mean (relative risk associated with the higher oxygen-saturation target, 1.08; 95 percent confidence interval, 0.69 to 1.69; P=0.70). When the primary outcomes were examined in the subgroup of 256 infants born before 28 weeks of gestation, the differences between the two treatment groups remained nonsignificant and were similar

Table 2. Measures of Growth and Development.*

Outcome	Standard-Saturation Group	High-Saturation Group	Mean Difference (95% CI)	Relative Risk or Odds Ratio (95% CI)†	P Value
38 Wk of postmenstrual age

* Plus–minus values are means ±SD. Denominators are the numbers of infants for whom growth measures or major developmental abnormalities could be assessed at 12 months of corrected age. CI denotes confidence interval.

† The value for a head circumference below the 3rd percentile is an odds ratio; other values are relative risks.

‡ Major developmental abnormalities were blindness, cerebral palsy, or a general quotient on the revised Griffiths Mental Developmental Scales that was more than 2 SD below the mean.

in magnitude to those in the whole cohort (data not shown).

SECONDARY OUTCOMES

The proportion of infants who were still dependent on supplemental oxygen at 36 weeks of postmenstrual age was 46 percent in the standard-saturation group and 64 percent in the high-saturation group (P<0.001) (Table 3). Similarly, the proportion of infants requiring home-based oxygen therapy was significantly lower in the standard-saturation group than in the high-saturation group (17 percent vs. 30 percent, P=0.004) (Table 3). The duration of oxygen supplementation was significantly higher in the high-saturation group: the postmenstrual age at the cessation of oxygen therapy was 35.4 weeks in the standard-saturation group and 37.9 weeks in the high-saturation group (P<0.001) (Table 3). There were no significant differences between the two groups in the median total duration of assisted ven-

Table 3. Rates of Adverse Outcomes among the Infants.*

Outcome	Standard-Saturation Group (N=178)	High-Saturation Group (N=180)	Relative Risk or Odds Ratio (95% CI)†	Median Difference (95% CI)	P Value
Dependence on supplemental oxygen at 36 wk of postmenstrual age — no. (%)	82 (46)	116 (64)	1.40 (1.15 to 1.70)		<0.001

Ablative retinal surgery for severe retinopathy of prematurity — no. (%)‡	20 (11)	11 (6)	0.54 (0.27 to 1.10)		0.09
Death (after randomization) — no. (%)	5 (3)	9 (5)	1.82 (0.53 to 7.05)		0.41

* CI denotes confidence interval.
† The value for death is an odds ratio; all other values are relative risks.
‡ Data are for infants who underwent cryotherapy or laser therapy for threshold retinopathy of prematurity, usually stage 3 with dilatation of the posterior retinal vessels (referred to as "plus" disease).

tilation after randomization, the rate of use of postnatal corticosteroids or diuretics, the length of the hospital stay after randomization, the postmenstrual age at discharge, or the time before the infant was able to be fed entirely orally (Table 3).

There were no significant differences between the groups in the rates of retinopathy of prematurity of any stage or in the frequency of the need for ablative retinal surgery (in 20 of 178 infants in the standard-saturation group [11 percent] and 11 of 180 infants in the high-saturation group [6 percent], P=0.09) (Table 3). All the infants who underwent ablative retinal surgery were born before 28 weeks of gestation, and all but one of these infants retained vision in at least one eye. The rate of ablative retinal surgery among infants born before 28 weeks of gestation was 16 percent (20 of 124 infants) in the standard-saturation group and 8 percent (11 of 132 infants) in the high-saturation group (relative risk, 0.52; 95 percent confidence interval, 0.26 to 1.03; P=0.06).

There was no significant difference between the two groups in the number of infants who died: five infants in the standard-saturation group and nine in the high-saturation group (Table 3). Of these deaths, one in the standard-saturation group was due to pulmonary causes, as compared with six in the high-saturation group (P=0.12). The number of infants who were rehospitalized and the number of health service visits per infant during the first year of life did not differ significantly according to the treatment group (Table 4). There were also no significant differences between the two groups in the measures of maternal postnatal depression, infant or toddler temperament, parental stress, or effects on the family (Table 4). Follow-up rates for these tests ranged from 71 to 77 percent.

DISCUSSION

Our double-blind, randomized trial showed no evidence that the targeting of a functional oxygen-saturation range of 95 to 98 percent rather than a range of 91 to 94 percent had a beneficial effect on growth or development in preterm infants with a long-term dependence on supplemental oxygen. The targeting of higher oxygen-saturation levels resulted in a 40 percent increase in the proportion of infants who were still receiving oxygen therapy at 36 weeks of postmenstrual age and a 78 percent increase in the

Table 4. Use of Health Services in the First Year of Life and Psychosocial Measures in Parents and Infants.*

Outcome	Standard-Saturation Group	High-Saturation Group	Relative Risk (95% CI)	Difference between Groups (95% CI)†	P Value
Infant rehospitalized — no./total no. (%)	82/171 (48)	92/170 (54)	1.13 (0.92 to 1.39)		0.34
No. of health service visits/infant				3.8 (−0.8 to 8.5)	0.11
Median	27.5	31.3			
Interquartile range	25.1 to 30.4	27.3 to 34.8			
Scores on psychosocial measures‡					
Edinburgh Postnatal Depression Scale (mother)	5.9±5.1	6.5±4.8		0.6 (−0.6 to 1.8)	0.32
Infant Temperament Scale	2.3±0.7	2.4±0.7		0.1 (0.0 to 0.3)	0.06
Toddler Temperament Scale	3.2±0.6	3.1±0.6		−0.1 (−0.2 to 0.1)	0.59
Parenting Stress Index, Short Form	71.7±20.6	72.9±21.1		1.2 (−3.9 to 6.3)	0.65
Impact-on-Family Scale	40.0±11.0	39.8±11.7		−0.2 (−3.0 to 2.6)	0.89

* Plus–minus values are means ±SD. Scores on the Edinburgh Postnatal Depression Scale[30] range from 0 to 30, with higher scores indicating a greater severity of depressive symptoms. Scores on the Infant Temperament Scale[31] range from 1 to 6, with a mean (±SD) of 2.5±0.64; higher scores indicate a more difficult temperament. Scores on the Toddler Temperament Scale[32] range from 1 to 6, with a mean of 3.46±0.62; higher scores indicate a more difficult temperament. Scores on the Parenting Stress Index, Short Form,[33] range from 32 to 160, with a median of 69 (interquartile range, 61 to 79); higher scores indicate greater parental stress. Scores on the Impact-on-Family Scale[34] range from 19 to 76, with a mean of 46.2±7.6; higher scores indicate increased effects on the family. CI denotes confidence interval.

† The mean difference is shown for scores on psychosocial measures; the median difference is shown for health service visits.

‡ The score on the Infant Temperament Scale was obtained at 4 months of corrected age; scores on the other measures were obtained at 12 months of corrected age.

proportion receiving supplemental oxygen after discharge. Hence, one could expect one additional case of home-based oxygen therapy for every eight infants treated if higher target ranges for the oxygen saturation were used routinely.

The finding that oxygen therapy was required for a longer period in the high-saturation group might simply be explained by the fact that a higher target saturation had to be reached for oxygen therapy to be discontinued. However, a higher target oxygen saturation may also be associated with potential pulmonary toxicity. The unexpected finding of excess deaths from pulmonary causes among infants in the high-saturation group — albeit not statistically significant — accords with the findings of the only other trial in which preterm infants were randomly assigned to different target oxygen-saturation ranges, the Supplemental Therapeutic Oxygen for Prethreshold Retinopathy of Prematurity (STOP-ROP) trial.[39] That trial showed an increased rate of adverse pulmonary sequelae (although not an increased rate of death due to pulmonary causes) among preterm infants with prethreshold retinopathy of prematurity when a higher oxygen-saturation range was targeted.

Oxygen toxicity, particularly in preterm infants, can inhibit lung healing and contribute to ongoing lung injury.[40] In our trial, infants who were still dependent on supplemental oxygen at 36 weeks of postmenstrual age or before discharge did not routinely have oxygen-saturation data collected after a room-air breathing test, and we do not have information on the proportion of infants in the high-saturation group who would not have required oxygen had their oxygen-saturation target been lower. Thus, the cause of the greater oxygen requirement in the high-saturation group remains uncertain.

Although our trial did not have the statistical power to detect differences in secondary eye-related outcomes, the effect of different target oxygen-saturation ranges on retinopathy of prematurity is of interest, since infants were randomly assigned to the different treatments at 32 weeks of postmenstrual age, before threshold retinopathy of prematurity usually develops. The results of both the STOP-ROP trial and our trial suggest the possibility that the need for ophthalmic intervention may be reduced when a higher oxygen-saturation range is targeted in a subgroup of extremely preterm infants with more severe eye disease. However, the differences between the treatment groups were not significant at the $P<0.05$ level in our subgroup analysis, and this hypothesis requires confirmation in larger studies.

Our trial addressed only the question of the effects of two different target oxygen-saturation ranges in preterm infants who remained dependent on supplemental oxygen after 32 weeks of postmenstrual age. Hence, these results should not be extrapolated to practice recommendations for preterm infants at earlier postmenstrual ages. The question of the most appropriate oxygen-saturation range for preterm infants treated sooner after birth can be answered only in the context of further large, well-designed, randomized trials with good long-term follow-up.[21]

A possible limitation of the study is that the duration of follow-up may not have been sufficiently long to allow us to detect other clinically important outcomes, such as minor disabilities that may become manifest later in childhood. We found no significant difference in the rates of developmental scores that were more than 1 SD but less than 2 SD below the mean — an outcome that may be a surrogate for later minor disability.[41]

The results of this randomized trial contradict observational reports suggesting that there are benefits of the routine targeting of higher oxygen-saturation levels in preterm infants with a long-term dependence on supplemental oxygen.[13-16] We found no evidence of beneficial effects of higher oxygen-saturation levels on growth or neurodevelopmental outcomes in these infants, but we did find an increased burden on health services.

In response to the comments and concerns of the DSMC, the SUPPORT committee held a conference call Monday Nov 28th at 10:00 to 1130AM to prepare a response.

- The DSMC made the following 2 comments in their letter regarding the SUPPORT trial. This was generated after they reviewed the oximeter data, which was corrected back to actual SpO2 values from the altered values displayed at the bedside:

1. There is a significant safety and exposure issue for the infants in the high saturation treatment group because an unacceptably high proportion of time was spent by these study subjects in the >95% range

2. There is a futility concern for this arm of the trial in that there does not appear to be substantial separation between the two high and low saturation treatment groups, and the babies are not being kept in the target range the appropriate amount of time in order to meaningfully test the oxygen saturation intervention as originally designed.

Based on these two issues, the consensus of the Committee was to recommend stopping the oxygen saturation arms of the SUPPORT trial due to safety and futility concerns.

We have responded to each of these concerns and our responses are detailed below

Response to Issue Number 1

We appreciate the concern expressed by the DSMC regarding a potential safety issue secondary to durations of SpO2 values > 95%. To date there are no prospective data which define the SpO2s experienced by the ELBW infant from birth as part of usual clinical care. Because no published studies have evaluated the effects of different target SpO2 ranges on important outcomes, this was one of the principle reasons for the design and conduct of the SUPPORT trial. A number of studies have evaluated different alarm limits, but have not reported the actual durations of SpO2 in the various ranges. Nghiem et al in a PAS abstract this year reported that nurses caring for ELBW infants believe that an acceptable oxygen saturation range should include higher upper limits than specified by current policy (Nghiem et al, Nursing Opinions and Practices of Oxygenation in Prematures: The NOPOP Study PAS #3415, 2005). The study by Hagadorn reported as a late breaker at the PAS this year (Hagadorn et al, Actual vs Intended Pulse Oxygen Saturation (SpO2) in Infants <28 Weeks Gestation. PAS 2005, Attached) did report on the experience of monitoring the actual SpO2 for 72 hours in the first 4 weeks of life in 72 ELBW infants. They reported that the "lower limits of intended ranges at study centers varied between 83-92%, upper limits 92-98%. Infants were monitored for a median of 70 hours (25th-75th percentiles 67-71 hr) during each week. Overall median SpO2 for infants on supplemental O2 during the first 4 weeks was 95% (25th-75th percentiles 91-97%; range of study center medians 91-96%). Centers ranged between 16-71% compliance with their individual intended SpO2 range. Most noncompliance was above intended range." In comparing the data evaluated to date by the DSMC, it is of interest that the mean SpO2 in the 2 Oximeter arms is 90% and 92%, with

medians of 92% and 94%, all of which are below that reported by Hagadorn et al (median=95). The 2 other relevant trials, STOP-ROP and BOOST, both enrolled infants at about 32 weeks PCA, and maintained 2 levels of SpO2, 89% to 94% and 91-94% versus 95% to 98% and 96% to 99%, by administration of oxygen. These studies achieved reasonable separation, but did demonstrate substantial overlap of the intended ranges. It is important to note that these studies were testing two ranges both of which were higher than the lower range of the SUPPORT trial (85% to 89%) and were treating infants who, for the most part, had recovered from their acute disease. In the BOOST trial 70% of the enrolled infants were < 28 weeks of age at birth (all of SUPPORT is < 28 weeks), 32 weeks postmenstrual age (PMA), and required oxygen at enrollment (Askie et al, New England Journal of Medicine. 2003; 349(10):959-967). The STOP-ROP trial enrolled infants with pre-threshold ROP at a PMA of 35.4 + 2.5 weeks of age (Phelps et al, Pediatrics. 2000; 105(2):295-310). These trials then gave the higher SpO2 range infants additional oxygen to increase their SpO2 to the desired range. STOP-ROP reported that the infants in the high range had an SpO2 > 95% for > 97% of the monitored time. These studies found an overall increase in pulmonary morbidity in the higher SpO2 range infants.

Examination of oximeter data from one if the NRN sites (Case Western, Walsh et al) obtained for an ongoing study evaluating infants similar to those enrolled in SUPPORT, and managed with conventional oximeters revealed that for the 9 infants for whom results were available that the percentage of time with and SpO2 > 95% was > 50%.

The oximetry algorithm that was designed for the SUPPORT trial is such that re-conversion of the altered oximeter values does not result in a discrete SpO2 number for every displayed value. SpO2 values, of 93%, 94% 95% and 96% will all be reconverted to a single value in one arm, while 84%, 85%, 86% and 87% will be reconverted to a single value in the other arm. This is a result of having the displayed values return to non-skewed SpO2 values at < 84% and > 96%, a safety design felt to be important by all involved in this trial (See Attached file USCD1). Thus the percentages reported to the DSMC for some of the ranges that include these values were not an accurate representation of the true values. However all values > 96% and < 84% are actual and do not require any conversion.

Percent of time of spent at SpO2 < 84% and > 96%
(RTI, Nov 29, 2005, 14:00 Hrs)

Range	High target (91-95)	Low target (85-89)
< 84%	8.51	16.62
> 96%	22.69	13.60

In the current SUPPORT study, an initial analyses utilizing only unaltered SpO2 values as shown above , ie those below 84% and above 96% have shown that one arm had an SpO2 > 96% for 13.6% versus 22.69% of the time for the comparison arm, and the durations of an SpO2 < 84% was also different at

16.62% versus 8.51%. The previously reported value of 36% duration of an SpO2 > 95% for one group represented an artifact of the conversion algorithm as described above. The values for SpO2s > 96% using unaltered data suggests that the SUPPORT trial to date has, if anything, reduced the duration of hyperoxia.

In addition, using these values which represent actual SpO2 values, we can state that the infants in this trial are spending approximately 70% of the time with a true SpO2 value between 84% and 96%. We believe that this is information is very encouraging, and suggests that if we are able to further improve adherence to the target ranges that we will achieve an adequate separation between the groups.

As part of the SUPPORT trial, we collect information about inhaled oxygen concentration 3 times a day for the first 14 days and daily thereafter. We believe that a more frequent documentation of inhaled oxygen will allow us to determine the actual duration of oxygen exposure. At the present an infant is considered to be receiving supplemental oxygen if he/she requires oxygen for greater than 2 hours. This results in infants being categorized as receiving supplemental oxygen for significant periods when they are actually in room air. This would result in durations of SpO2 greater than 95% that were felt to be modifiable and reported as such when in fact there is no effective treatment for such elevated SpO2s. In addition, we do not know if such SpO2s on room air are associated with any morbidity. From the SUPPORT study data analyses to date we know that infants in room air have SpO2s > 95% for 46% to 69% of the time.

In view of this design, we would suggest that all future analyses evaluate the ranges of <84% and >96% as those ranges that are considered to be low and high.

We believe that the SUPPORT trial will actually define the periods of time that ELBW infants spend with different ranges of SpO2, and that it is essential to collect this information. In addition, as our findings indicate a lower true percent of the time at SpO2 values >95%, and lower median SpO2 values than has previously been reported, we are in fact, reducing the time with high SpO2 values compared to usual care. The SUPPORT trial carefully evaluates risks, and we will be evaluating group differences for all important short and long term outcomes.

The SUPPORT trial methodology actively encourages all caretakers to keep SpO2 < 96% by having alarm limits set at 85% to 95%. These limits were utilized because it was felt that these represented current practice. The oximetry algorithms were designed to keep infants in the narrower target range of 88% to 92% with the realization that setting alarm limits at these values would severely increase the frequency of the alarms sounding. Nevertheless, our results to date suggest that we have decreased the expected percent of time > 95%, and in one group the value of 14% may be as low as is achievable in an actual clinical environment.

We believe that the SUPPORT study will define the durations of high and low SpO2 and will be able to determine if there is a threshold duration of either value that is associated with altered outcomes, and for this reason alone, the

SUPPORT trial will be very valuable. All of the procedures outlined below in response to your second concern will also allow us to further increase the percentage of time that the infants are in the maximally altered SpO2 ranges which we believe will further increase separation of these groups.

Response to Issue Number 2

There is concern that we have not achieved adequate separation by the current oximeters and study personnel. Reviewing the newest analyses available as described above, there are differences in the durations of low and high SpO2s between the 2 oximeter groups. In addition, a careful analysis of the most recent converted values demonstrates that the cumulative time spent with an SpO2 of 90% or less is 24.3% versus 43%, for the 2 oximeter groups, supporting the ability of the altered oximeters to produce differential SpO2 exposures. We do acknowledge that it would desirable to increase the percentage of time in the narrower target range and towards this end would propose the following changes to SUPPORT:

1. We will require documentation that the alarm limits are set and functional as per protocol every 4-6 hours. We have found that in some units the high alarms are being defeated, and thus believe that such documentation will greatly assist in decreasing the actual time that the SpO2 is > 96%. This task will be assigned to the respiratory therapists, and this procedure is already being done in many NRN units.

2. We will immediately initiate a change in our data collection for FiO2. We will change the data form to indicate that the infant was either in oxygen for the entire 24 hours, and if not, will check off the actual hours of oxygen exposure, and we will continue with this from of data collection for the entire time that the infant is receiving oxygen. In the current protocol we collect such information 3 times a day for the first 14 days only and then daily thereafter. We believe that more frequent documentation will allow us to determine the actual time that an infant is in room air. At the present the infant is considered in oxygen if he/she requires oxygen for greater than intermittent use. This results in infants being categorized in oxygen for significant periods when they are in room air. While in room air, we cannot manipulate the SpO2, and thus knowledge of the true time in oxygen will produce a more accurate representation of oximetry results that are subject to care interventions.

3. We will initiate further training and in-service at all the sites to stress the importance of keeping the SpO2 alarm functional and at the limits of 85% and 95%. In the past these were guidelines, and we will now change the study manual and protocol to indicate these limits are now set by protocol and that violations will be documented. We will encourage all caretakers to aim for an SpO2 value of 90% and make every effort to educate caretakers to make smaller

adjustments in FiO2 and ensure that the infant is maintained between the 87% to 93%, the range with the maximal separation of the study oximeters. We will further facilitate the use of the 2 hour and 12 hour histograms showing the infants' actual ranges to provide feedback to the caretakers regarding the percentage of time in the target ranges.

4. We will develop guidelines for managing desaturations such that the increase in oxygen is proportional to the desaturation. We would hope that such changes – ie increasing the FiO2 in steps of 5% as opposed to much larger increases will decrease the resultant overshoots creating the high SpO2 values. This will be included in the revised manual of operations.

5. We will place bedside cards to indicate the target range.

6. We will initiate compliance monitoring visits coordinated by RTI to visit random sites. These visits had been planned, but had not yet been initiated. The teams will consist of a member of RTI and a study coordinator, and they will review the adherence to the protocol and any other relevant issues.

We thank the DSMC for their thoughtful concerns. We trust that our plans to move forward with the SUPPORT trial are acceptable to the DSMC. We are anxious to initiate the above changes, seek IRB approvals and re-activate this trial.

LATE BREAKER ABSTRACT SUBMISSION FORM

Abstracts and Payment must be RECEIVED by March 1, 2004

~ Abstracts must be submitted electronically using this form.
~ Abstracts, inclusive of title, authors, institutions, and graphs/tables, must fit in a 6.5 inch x 4 inch space between the two lines (appx. 2,600 characters). Use a font no smaller than 10 pt.
~ You must complete all information and include payment ($50 US) for your abstract to be considered.

Actual vs Intended Pulse Oxygen Saturation (SpO2) in Infants <28 Weeks Gestation

J Hagadorn [1,2], A Furey [1], TH Nghiem [1], S Greene [1], E Abban [1], J Cho [1], P Shrestha [1], A Vora [1], M Landa [2], C Schmid [2], P Hibberd [2], CH Cole [1] and The AVIOx Study Group. [1]Div Newborn Med and [2]Div of Clin Care Research, Tufts-New England Med Ctr, Boston, MA.

Background: Detailed data are not available regarding the actual versus intended SpO2 in infants born <28 weeks gestation (extremely premature newborns, EPNs) in the neonatal period during routine care. **Objective:** To document actual SpO2 in EPNs in the first 4 weeks of life during routine care and compare to the level recommended by local policy/guideline. **Design/Methods:** EPNs <96 hours old were enrolled in a prospective multicenter cohort study. Oximetry data were collected every 2 seconds with masked signal-extraction oximeters for 72 hours in each of the first four weeks of life. Data were compared to SpO2 range prescribed by local institutional policy. **Results:** 14 centers from 3 countries enrolled 78 infants with mean birth weight 863 g (SD 208 g) and mean gestational age 26 wk (SD 1.4 wk). Lower limits of intended ranges at study centers varied between 83-92%, upper limits 92-98%. Infants were monitored for median of 70 hours (25^{th}-75^{th} percentiles 67-71 hr) in each week. Overall median SpO2 for infants on supplemental O2 during the first 4 weeks was 95% (25^{th}-75^{th} percentiles 91-97; range of study center medians 91-96). Centers ranged between 16-71% compliance with intended SpO2 range. Most noncompliance was above intended range. **Conclusions:** Compliance with intended SpO2 range during routine care varied substantially among participating centers, and was generally poor regardless of intended level. These data will assist quality improvement and education efforts, and will aid planning of prospective randomized trials examining level of oxygenation. **Disclosure:** Funded by the SPR Student Research Program; Fight for Sight/Prevent Blindness America; The Tufts-NEMC Research Fund; GCRC/Natl Center for Research Resources MO1-RR00054, and NEI K23 EY/HD00420. Oximeters provided by Masimo Corp.

Briefly describe the reason why the December deadline could not be met:
Study still in progress at December deadline, with only about 60% of enrollment achieved.

Supplemental Therapeutic Oxygen for Prethreshold Retinopathy of Prematurity (STOP-ROP), A Randomized, Controlled Trial. I: Primary Outcomes

The STOP-ROP Multicenter Study Group*

ABSTRACT. *Objective.* To determine the efficacy and safety of supplemental therapeutic oxygen for infants with prethreshold retinopathy of prematurity (ROP) to reduce the probability of progression to threshold ROP and the need for peripheral retinal ablation.

Methods. Premature infants with confirmed prethreshold ROP in at least 1 eye and median pulse oximetry <94% saturation were randomized to a conventional oxygen arm with pulse oximetry targeted at 89% to 94% saturation or a supplemental arm with pulse oximetry targeted at 96% to 99% saturation, for at least 2 weeks, and until both eyes were at study endpoints. Certified examiners masked to treatment assignment conducted weekly eye examinations until each study eye reached ophthalmic endpoint. An adverse ophthalmic endpoint for an infant was defined as reaching threshold criteria for laser or cryotherapy in at least 1 study eye. A favorable ophthalmic endpoint was regression of the ROP into zone III for at least 2 consecutive weekly examinations or full retinal vascularization. At 3 months after the due date of the infant, ophthalmic findings, pulmonary status, growth, and interim illnesses were again recorded.

Results. Six hundred forty-nine infants (325 conventional and 324 supplemental) were enrolled from 30 centers over 5 years. Five hundred ninety-seven (92.0%) infants attained known ophthalmic endpoints, and 600 (92%) completed the ophthalmic 3-month assessment. The rate of progression to threshold in at least 1 eye was 48% in the conventional arm and 41% in the supplemental arm. After adjustment for baseline ROP severity stratum, plus disease, race, and gestational age, the odds ratio (supplemental vs conventional) for progression was .72 (95% confidence interval: .52, 1.01). Final structural status of all study eyes at 3 months of corrected age showed similar rates of severe sequelae in both treatment arms: retinal detachments or folds (4.4% conventional vs 4.1% supplemental), and macular ectopia (3.9% conventional vs 3.9% supplemental). Within the prespecified ROP severity strata, ROP progression rates were lower with supplemental oxygen than with conventional oxygen, but the differences were not statistically significant. A post hoc subgroup analysis of plus disease (dilated and tortuous vessels in at least 2 quadrants of the posterior pole) suggested that infants without plus disease may be more responsive to supplemental therapy (46% progression in the conventional arm vs 32% in the supplemental arm) than infants with plus disease (52% progression in conventional vs 57% in supplemental).

Pneumonia and/or exacerbations of chronic lung disease occurred in more infants in the supplemental arm (8.5% conventional vs 13.2% supplemental). Also, at 50 weeks of postmenstrual age, fewer conventional than supplemental infants remained hospitalized (6.8% vs 12.7%), on oxygen (37.0% vs 46.8%), and on diuretics (24.4% vs 35.8%). Growth and developmental milestones did not differ between the 2 arms.

Conclusions. Use of supplemental oxygen at pulse oximetry saturations of 96% to 99% did not cause additional progression of prethreshold ROP but also did not significantly reduce the number of infants requiring peripheral ablative surgery. A subgroup analysis suggested a benefit of supplemental oxygen among infants who have prethreshold ROP without plus disease, but this finding requires additional study. Supplemental oxygen increased the risk of adverse pulmonary events including pneumonia and/or exacerbations of chronic lung disease and the need for oxygen, diuretics, and hospitalization at 3 months of corrected age. Although the relative risk/benefit of supplemental oxygen for each infant must be individually considered, clinicians need no longer be concerned that supplemental oxygen, as used in this study, will exacerbate active prethreshold ROP. *Pediatrics* 2000;105:295–310; *retinopathy of prematurity, oxygen therapy, visual loss, oxygen toxicity, prematurity, neonatal outcomes, bronchopulmonary dysplasia.*

ABBREVIATIONS. ROP, retinopathy of prematurity; CRYO-ROP,

cryotherapy for ROP; STOP-ROP, Supplemental Therapeutic Oxygen for Prethreshold ROP; PMA, postmenstrual age; SES, socioeconomic status; CLD, chronic lung disease; CPAP, continuous positive airway pressure; OR, odds ratio; CI, confidence interval.

Retinopathy of prematurity (ROP) is a neovascular retinal disorder that develops in 84% of premature survivors born at <28 weeks' gestation. Fortunately, ROP resolves in most cases (80%) without visual loss from retinal detachments or scars.[1,2] The multicenter study of cryotherapy for ROP (CRYO-ROP) study showed that, when the disorder progresses, ablation of the avascular peripheral retina with cryotherapy reduced the incidence of retinal detachment from 51% to 31%.[3] Peripheral retinal ablation, now usually by laser therapy, has become standard treatment for advanced ROP.[4–7] However, this therapy is not always successful in halting the progression of ROP, and the long-term complications of extensive ablation of the developing peripheral retina beyond 5 years of age[7] are as yet unknown.

In 1948, Michaelson[8] proposed that a gradually increasing oxygen deficit of the oxygen-consuming retina during normal differentiation causes release of an angiogenic growth factor. Based on this supposition, therapeutic administration of supplemental oxygen to relieve the putative hypoxic stimulus for retinal neovascularization has been considered. In the 1950s, Szewczyk[9] and Bedrossian et al[10,11] first reported the use of supplemental oxygen to treat the neovascularization in ROP. This approach was abandoned after the 1956 Cooperative Study of Retrolental Fibroplasia demonstrated that prolonged (4 weeks) administration of 50% oxygen caused increased rates of ROP and vision loss.[12] But the concept of an hypoxic stimulus for retinal neovascularization remained biologically plausible and eventually regained scientific interest and attention.

Case–control studies revealed that infants who develop severe ROP, compared with infants of similar gestation and birth weight who do not have ROP, have hospital courses characterized by more complex medical problems, prolonged oxygen requirements, lower overall arterial oxygenation levels, and more episodes of fluctuating blood oxygen levels.[13–15] In contrast to healthy neonates breathing room air, whose arterial oxygen levels are similar to those of adults (95–100 mm Hg [13 pKa]), the recommended arterial concentrations for premature infants receiving oxygen are 50 to 80 mm Hg (6.6–10.6 kPa).[16] This relative hypoxia in premature infants raised the possibility that supplemental oxygen might be used to improve retinal oxygenation and down-regulate retinal neovascularization. Tests of the effects of such oxygen supplementation in animal models of ROP supported this hypothesis,[17,18] and a reported benefit of supplemental oxygen in a clinical case series[19] provided additional support for systematically testing the hypothesis in premature infants with ROP. We report the primary results from the Supplemental Therapeutic Oxygen for Prethreshold ROP (STOP-ROP) study, which was designed to test the hypothesis that supplemental oxygen, given to attain a pulse oximetry range of 96% to 99% saturation, would reduce by one third the proportion of infants with at least 1 eye progressing from moderate ROP (prethreshold) to threshold ROP requiring peripheral ablative surgery, without unacceptable side effects.[20]

METHODS

Study Design

The study design was a randomized trial comparing the effects of 2 oxygenation strategies on the progression of ROP: conventional oxygenation at a pulse oximetry target of 89% to 94% versus supplemental oxygen to achieve a pulse oximetry target range of 96% to 99%.[21] From February 1994 to March 1999, eligible patients from 30 centers were typically enrolled by telephone call to the central coordinating center (64%) after confirmation of eligibility and signed informed consent by parents or legal guardians. Random assignments were generated by the coordinating center using the Wei-Lachin Urn Scheme[22] and were stratified by center and by 2 levels of baseline ROP severity. When the coordinating center was not available, study centers used sequentially numbered, sealed envelopes provided in advance by the coordinating center to obtain treatment assignments, and submitted appropriate documentation to the coordinating center. An infant was assigned to the severe ROP stratum A whenever either study eye had 1 or more clock hours of any stage ROP in zone I, or when the fellow eye was already at threshold or worse ROP (see Table 1), thereby eliminating that eye as a study eye. The remaining infants fell in the less severe ROP stratum B with zone II prethreshold ROP in both eyes or in the second eye at less than prethreshold ROP. Family, bedside nurses, and attending neonatologists knew the treatment assignment, but the study-certified ophthalmologists who assessed eligibility, progression of the ROP, and study end-

TABLE 1. Definitions of ROP Severity Categories for STOP-ROP

Threshold ROP*	
Zone II	Presence of posterior pole dilation/tortuosity in at least 2 posterior pole quadrants (plus disease), and stage 3 ROP for at least 5 contiguous clock h or 8 composite clock h
Zone I	ROP (any stage) with posterior pole dilation/tortuosity in at least 2 posterior pole quadrants (plus disease), or stage 3 ROP, with or without plus disease
Beyond threshold	Stage 4 ROP, stage 5 ROP, or massive vitreal hemorrhage obscuring the view of the fundus
Prethreshold ROP	
Zone II	Any number of clock hours of stage 3 ROP, less than threshold severity, or any stage 2 ROP with at least 2 quadrants of posterior pole dilation/tortuosity disease (plus disease)
Zone I	Any ROP less than threshold severity

Stages and zones based on the international classification of ROP.[24]

* The definition of threshold ROP differs somewhat from that used in the CRYO-ROP study[4] in 2 ways: 1) In the CRYO-ROP study, "plus disease" was a global assessment of the posterior pole and was not determined according to number of quadrants involved, and 2) in the CRYO-ROP study, the definition of threshold was the same for both zone I and zone II and is the same as stated for zone II above (except for the number of quadrants of posterior pole dilation/tortuosity, as described in note 1). In STOP-ROP, a less stringent definition of threshold in zone I was used to accommodate the clinical judgment of a majority of the participating ophthalmologists that earlier treatment was needed to improve the poor outcomes of zone I threshold ROP.

points remained masked to treatment assignment throughout the study.

The primary endpoint of this study of systemic oxygen therapy was based on the infant, ie, progression of at least 1 study eye of an infant to threshold ROP (Table 1). Infants had only 1 study eye if the fellow eye was already at threshold or worse than threshold ROP at enrollment. Otherwise, they had 2 study eyes; even a fellow eye at less than prethreshold severity was considered a study eye, because it was going to be exposed to the assigned treatment and could progress to threshold ROP. Secondary endpoints included ophthalmic status at 3 months after due date, infant growth rates, developmental screening, and adverse medical events. The protocol was reviewed and approved by the institutional review board at each participating site before initiation of recruitment at that site.

Eligibility Criteria

Premature infants were screened for ROP, according to local guidelines consistent with the 1992 recommendations of the American Academy of Pediatrics,[16] at 71 hospitals affiliated with 30 certified participating centers throughout the United States. Infants with prethreshold ROP in at least 1 eye (Table 1) were registered as potentially eligible for the study and monitored for a minimum of 4 hours with continuous pulse oximetry. Registered candidates were excluded as ineligible whenever their median pulse oximetry was greater than 94% saturation while breathing room air or they had lethal anomalies or congenital anomalies of the eye. The family or guardian of eligible infants was approached for consent if the attending neonatologist agreed that randomization to either oxygen saturation target range could be achieved and would be medically safe, and that the infant's caretaker would be able to comply with the follow-up appointments. The diagnosis of prethreshold ROP in at least 1 eye then had to be confirmed independently by a second examiner to qualify for randomization. At least 1 of the 2 examiners had to be certified by the STOP-ROP study; usually both were.

Intervention

Although randomization and initiation of treatment within 24 hours of the diagnosis of prethreshold ROP was the goal, later enrollment was permitted as long as at least 1 eye was verified as remaining at prethreshold within the preceding 48 hours. The treatment assignment was for the infant to be placed on continuous pulse oximetry monitoring and to maintain oxygen saturation, as much as possible, in the target range of either 89% to 94% (conventional) or 96% to 99% (supplemental). Ohmeda 3740 pulse oximeters and laptop computers with software to monitor, record, and report trends in oxygen saturation were provided by the study for each infant. The Ohmeda 3740 pulse oximeter is calibrated at the factory to display a saturation lower by 1.6 saturation points, compared with other commercial oximeters, to correct for assumed carboxyhemaglobin and methemaglobin levels. Oximeters provided continuous data to a laptop computer that displayed real-time oxygen saturation summary graphs and tables updated every 20 seconds. The percent time in the assigned target range over varying time periods was displayed (Fig 1). Whenever the oxygen saturation was out of the target range for >10 of the previous 20 minutes and the saturation was currently out of range, the computer produced a unique alarm. The alarm limits on the oximeter itself were set according to the each hospital's usual policy. Using this continuous feedback, the bedside nurse or family could readily make necessary adjustments to the oxygen environment to maximize the time spent in the assigned target range. Pulse oximetry values were recorded to a computer disk every 40 seconds during the weeks the infant was on study equipment.

Study saturation targets continued for a minimum of 2 weeks, even if ophthalmic endpoints were reached in both eyes sooner. After those 2 weeks, treatment assignment and equipment were stopped after both eyes reached ophthalmic endpoints. Brief periods off equipment were allowed for procedures or baths. Occasionally an infant was ready for discharge home before reaching study endpoint in both eyes. The parents or guardians were then trained to use the study oximeter and computer to permit the assigned treatment to be continued, recorded, and completed at home.

Outcome Variables

Study-certified ophthalmologists and study center coordinators examined enrolled infants weekly until both eyes reached oph-

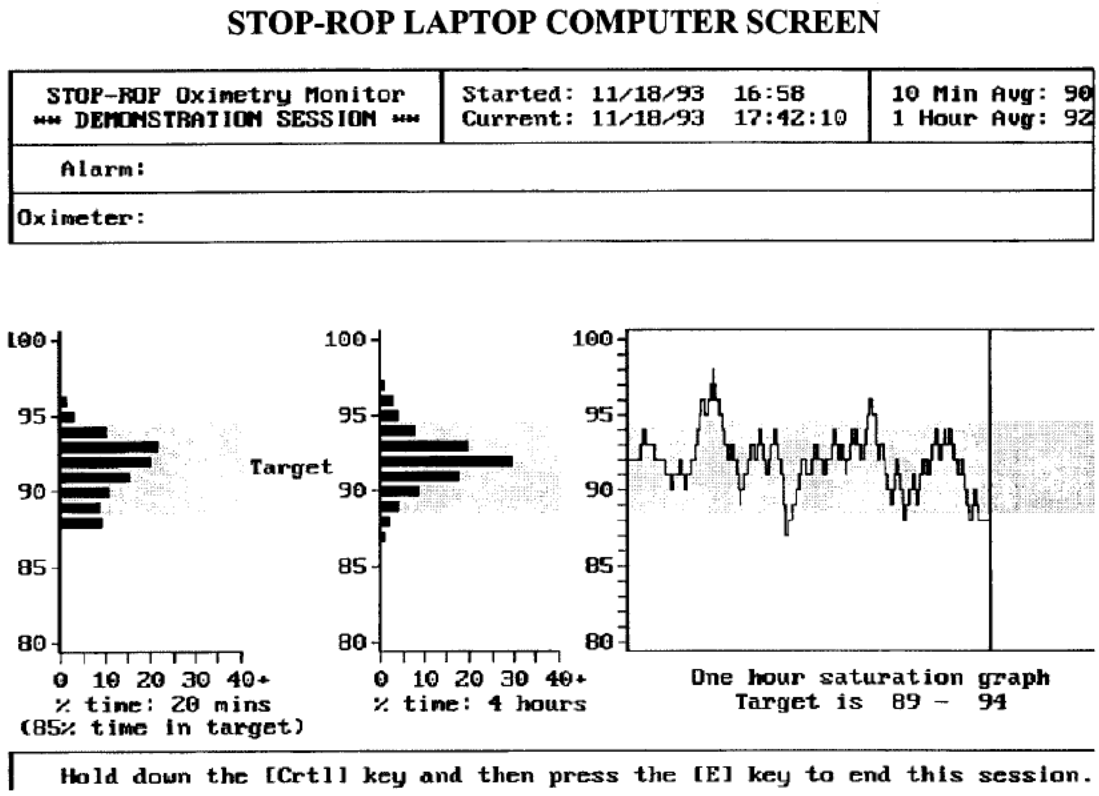

Fig 1. Computer screen format. Frequency distributions and oximetry strip chart information provided continuously at the bedside for nursing management of the pulse oximetry study targets. In this sample, the infant is assigned to the conventional arm (89%–94% saturation), the area highlighted in gray.

thalmic endpoints and again at 3 months' corrected age (that is, 3 months past the term due date of 40 weeks' postmenstrual age [PMA]). The computers and oximeters were covered during examinations to maintain masking of the ophthalmologists. To standardize diagnoses, all ophthalmologists were certified in the completion of study data forms. If they had not been previously certified during the acute phase of the CRYO-ROP or Light Reduction-ROP studies,[23] their use of the international classification of ROP[24] was certified by study headquarters through a series of dual examinations of infants with ROP. Standard fundus photographs of degrees of severity of posterior pole dilation/tortuosity were provided to each center for use at the bedside to promote uniformity of the diagnosis (Fig 2). For the STOP-ROP study, plus disease was defined as "at least 2 quadrants of dilation and tortuosity of the posterior pole vessels." Study personnel completed annual recertification throughout the study.

An adverse ophthalmic endpoint was defined as progression to threshold ROP (or worse), diagnosed by 1 study-certified ophthalmologist and confirmed independently by a second study-certified ophthalmologist. Eyes confirmed to have reached threshold ROP were referred for possible cryotherapy or laser therapy. The definition of threshold ROP (Table 1) in zone II was the same as that used by the CRYO-ROP study; however, in zone I, the definition was modified to permit a diagnosis of threshold at slightly less severity of ROP than required by the CRYO-ROP study because zone I threshold ROP, as defined in CRYO-ROP, progressed to poor retinal outcomes in 78% of eyes even with cryotherapy.[3]

A favorable ophthalmic endpoint was defined as regressing ROP in zone III for at least 2 successive weekly examinations, or full retinal vascularization. Ophthalmic outcomes at 3 months' corrected age were classified as: 1) unfavorable when there were findings of total or partial retinal detachment or when the visual axis was otherwise obstructed, 2) indeterminate when there was macular ectopia, or 3) favorable when there were only minor peripheral findings, laser or cryotherapy scars, or active ROP in zone II or III. The uncommon finding of continued active ROP at 3 months' corrected age was followed whenever possible with a repeat examination at 6 months' corrected age, although this situation had not been anticipated when the STOP-ROP protocol was developed. Whenever missed examinations or death caused incomplete endpoint dating or diagnosis of an eye's endpoint, all available eye data were provided to an ophthalmic endpoints committee of 3 ophthalmologists masked to the treatment assignment. The committee reached consensus on the outcome of each eye according to the following categories: 1) almost certainly reached adverse ophthalmic endpoint, 2) may have reached adverse ophthalmic endpoint, 3) indeterminate, 4) may have reached favorable ophthalmic endpoint, or 5) almost certainly reached favorable ophthalmic endpoint. Only consensus votes of 1 or 5 were used in any subsequent secondary analyses, and the committee was unaware of this analysis decision when they met (votes 2, 3, or 4 were treated as unknown).

Pediatric data were recorded at the time of randomization, at weekly intervals throughout the intervention period, and again at 3 months' corrected age. These data included duration of oxygen use and hospitalization after randomization; weight, length, and head circumference; use of diuretics, methylxanthines, or steroids; a checklist of specified adverse events; and episodes of rehospitalization. The age for achieving full nipple feeds was determined as the first day of 3 consecutive days of taking all enteral feedings by mouth. The questions for the Hollingshead classification of socioeconomic status (SES) were asked at discharge.[25] Adverse events, rehospitalizations, and deaths before 3 months' corrected age were reported as they occurred. The Revised Parental Denver Questionnaire was administered at 3 months' corrected age.[26]

All deaths and rehospitalizations were reviewed by 3 neonatologists masked to treatment assignment to determine whether pulmonary disease was the primary cause of death or rehospital-

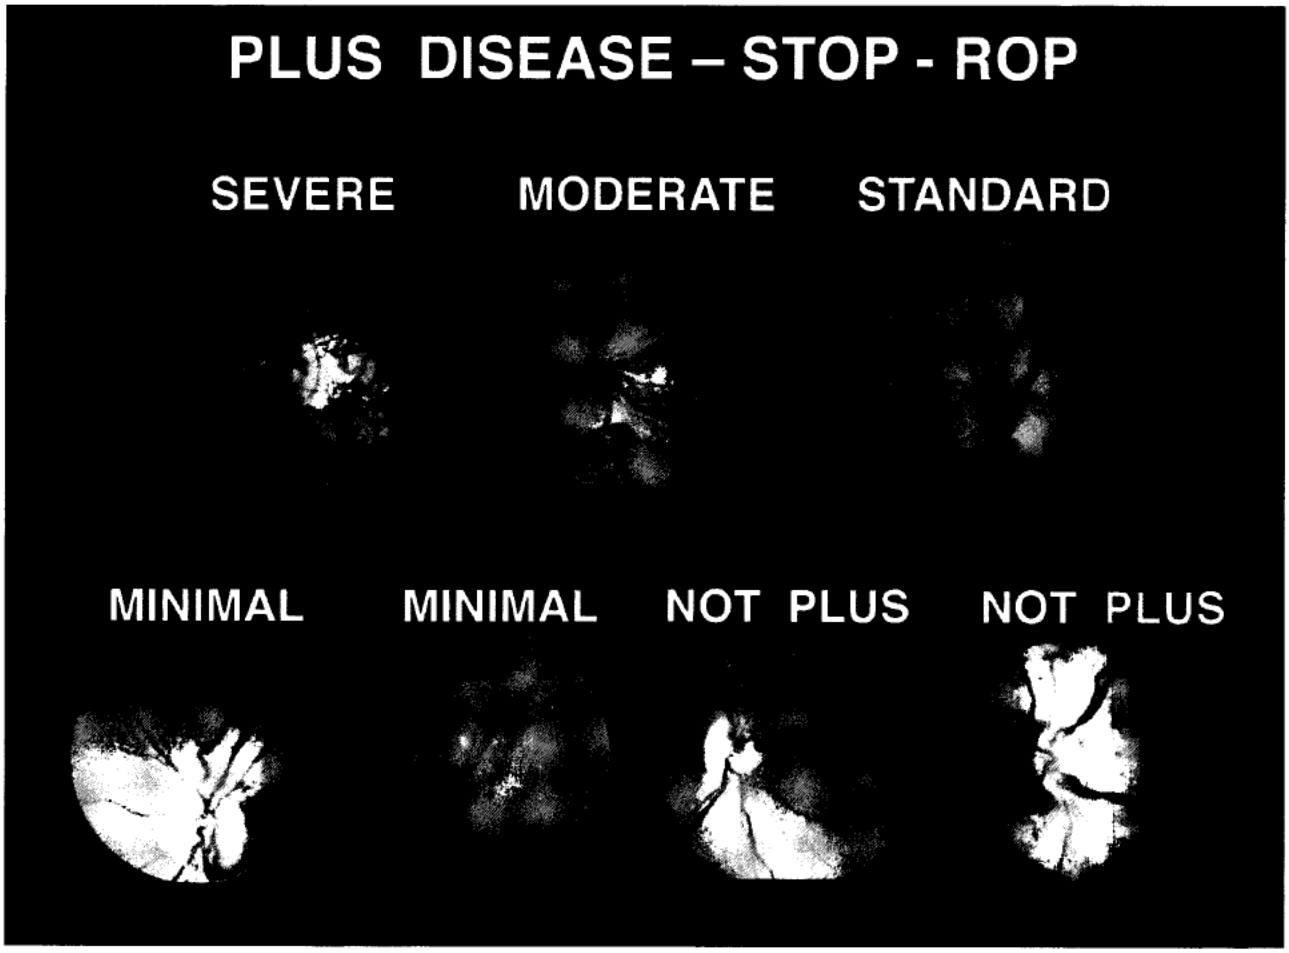

Fig 2. Standard photographs for the STOP-ROP study: fundus photographs of the posterior pole (visible with a direct ophthalmoscope), showing examples of mild to moderate posterior pole dilation/tortuosity and samples of retinas without this finding.

ization. Pneumonia/chronic lung disease (CLD) events were defined as probable or definite pneumonia, an acute exacerbation of CLD, or some combination of these 2 such that the study neonatologist could not distinguish between them.

Pulmonary Score

A composite pulmonary score was developed to describe the pulmonary status of each infant at baseline. The pulmonary score was calculated as:

$$\text{Pulmonary score} = (F_{IO_2})\,(\text{support}) + (\text{medications})$$

where F_{IO_2} is expressed as a fraction (room air = .21); support = 2.5 if on ventilator, 1.5 if on nasal or endotracheal continuous positive airway pressure (CPAP), and 1.0 if on nasal cannula, hood oxygen or off oxygen; and medications = .05 each for methylxanthines or intermittent diuretics, .10 for daily diuretics, .10 for inhaled steroids, and .20 for systemic steroids for CLD. Therefore, the pulmonary score could have a range of values between .21 (no pulmonary support, oxygen, or medications) and 2.85 (assuming that an infant would not be on both inhaled and systemic steroids). The baseline pulmonary score correlated well with pulmonary rehospitalizations, pulmonary deaths, and markers of CLD severity, such as duration of oxygen therapy (data not shown).

Sample Size and Data Monitoring

The progression rate to threshold was monitored by the Data and Safety Monitoring Committee at annual meetings. An early stopping guideline was constructed for ophthalmic benefit at an overall α-value of .025, and a stopping guideline for ophthalmic harm at an overall α-value of .10, allowing for repeated interim analyses[27] using the software of Reboussin (Madison, WI, University of Wisconsin, Department of Statistics). A sample size of 880 infants (to achieve 816 cases with final outcome data) was calculated as necessary to provide 90% power with an overall type I error rate of .025 to detect a one third reduction in progression to threshold disease or a 10% absolute reduction based on a predicted rate of progression of 30% in the conventional arm.[1] Adverse events were reviewed biweekly, and deaths were reviewed immediately by a neonatologist on the Data and Safety Monitoring Committee. All adverse events were reviewed at each meeting of the full Committee.

In 1997, the Data and Safety Monitoring Committee, after the enrollment of 449 children over 3.3 years, expressed concern about the ability of the study group to enroll the target number of 880 infants within 5 years, given consistent enrollment rates averaging 11.2 infants per month. Furthermore, new reports of nonrandomized case series in human infants suggesting a strong beneficial effect of supplemental oxygen,[28,29] as well as publication of additional animal model data,[30–35] supported the hypothesis of the STOP-ROP study, which might adversely affect enrollment. Calculations at that time showed that an enrollment of 633 infants completing the study would provide 83% power to detect a fall in the progression rate from 30% to 20%. The Committee members, who were not masked to study ophthalmic outcomes (although masked to treatment assignment) at the time of the review, recommended that recruitment continue through March 1999 with a revised enrollment goal of at least 633 infants. The final number of 649 enrollees, with ophthalmic endpoints available for 597, resulted in a power of ~80% against the designed alternative.

Statistical Analyses

Primary analyses were performed on all enrollees according to the assigned treatment arm (intention-to-treat) using the group-sequential method of Kim and DeMets.[27] Secondary categorical characteristics of the patients in the 2 arms were compared by χ^2 test, and group differences of continuous factors were compared with Student's t test and Wilcoxon rank-sum test. Logistic regression was used for the adjustment of progression rates for covariates. All P values presented are 2-sided and are unadjusted for the 5 interim examinations of the data, ie, are nominal P values, unless otherwise specified. Analyses were conducted with SAS software (SAS Institute, Cary, NC).[36]

RESULTS

Patients

Comparability of Enrolled and Registry Infants

From February 9, 1994, through March 31, 1999, 1847 infants with prethreshold ROP in at least 1 eye were registered at the participating centers. Of these, 634 (34%) were ineligible because either their pulse oximetry was greater than 94% in room air, or they had fatal or congenital eye anomalies (Fig 3). Of 1213 clinically eligible infants, 649 (54%) were enrolled. Reasons for nonenrollment were refusals of the family/guardians or the neonatologist (368), nonconfirmed prethreshold ROP (41), enrollment in conflicting studies (9), judgment that the infant was too ill to attempt randomization to the supplemental arm (28), inability of the family to comply with follow-up visits (41), imminent transfer to another hospital (8), and others. Of the ineligible infants, 99% had pulse oximetry greater than 94% in room air. Nonenrolled infants, including both those ineligible and those eligible but not enrolled (1198), weighed more at birth than enrolled infants (787 ± 287 vs 726 ± 160 g; $P < .001$) and had a slightly higher gestation at birth (25.7 ± 1.8 vs 25.4 ± 1.5 weeks; $P < .01$).

Comparability of Treatment Arms

Of the enrolled infants, 325 were randomized to the conventional arm, 324 to the supplemental arm, and their study completion rates are shown in Fig 3. The primary ophthalmic endpoint was available for 597 (92%) and was not recorded for 52 infants because of death (2), parental withdrawals from the study treatment (18), treatment with cryotherapy/laser before reaching ophthalmic endpoints (5), and missed eye examinations (27). Ophthalmic evaluations at 3 months' corrected age were completed for 600 infants and were unavailable for 49 because of death (16), withdrawal (31), and loss to follow-up (2). (Three additional infants in the supplemental arm not shown in the figure returned for just the neonatal portion of the 3-month evaluation). Rates of noncompletion were similar for both treatment arms (Fig 3).

Baseline demographic and pediatric characteristics are shown in Table 2, and ophthalmic baseline characteristics in Table 3. Randomization resulted in similar groups. Enrollment and randomization occurred at a PMA (PMA = gestational age at birth plus chronological age) of 35.4 ± 2.5 weeks (range: 30–48 weeks). The baseline pulmonary severity score and the mode of oxygen support were similar between the 2 arms. Many infants were on diuretics (54%) and methylxanthines (70%), and 29% had received steroids for CLD in the week before enrollment.

The ophthalmic baseline characteristics shown in Table 3 were also similar between the conventional and supplemental arms. There were no significant differences between the treatment arms in the number of infants enrolled in each ROP severity stratum or substratum. For the more severe forms of ROP represented in stratum A, 4.3% of enrollees had 1 eye at or beyond threshold (therefore, only 1 study eye), and 23.4% had 1 or both eyes with at least 1 clock hour of ROP in zone I. In stratum B, infants with

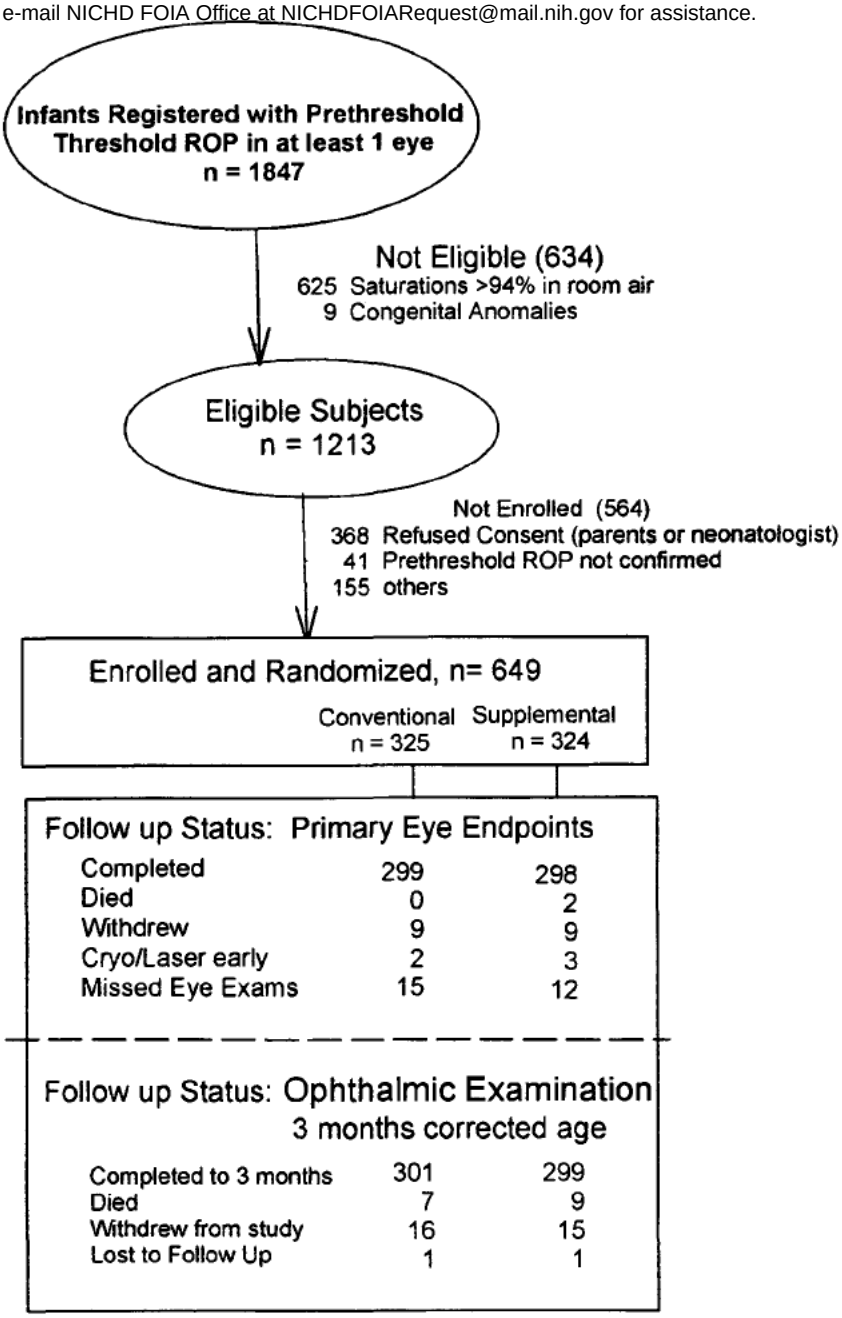

Fig 3. Patient enrollment flow diagram. There were several subjects without primary ophthalmic endpoints who nonetheless continued with follow-up examinations; therefore, there are more completed 3-month examinations than primary ophthalmic endpoints. Three additional supplemental infants completed the 3-month neonatal outcome examination, although they failed to complete the ophthalmic 3-month examination (not shown in figure).

zone II ROP in both eyes comprised 51% of all enrollees, and the remaining 21% entered the trial with the prethreshold eye's fellow eye at less than prethreshold ROP. There were no significant differences between the 2 arms in the number randomized within the first 24 hours after observing prethreshold ROP and in the numbers randomized after a longer period (Table 3). The elapsed time from the first diagnosis of prethreshold ROP to randomization was <24 hours in 33% of infants and >48 hours in 27% of infants.

Adherence to the Protocol

Oxygen requirements increased significantly for the infants randomized to the supplemental range. The average oxygen concentration increased from 36% ± 14% pretreatment to 46% ± 20%, 24 hours after randomization for those infants on a ventilator, CPAP, or hood oxygen; the average increase was 9.5% ± 16.5%. For infants on nasal cannula, the interactions between flow, infant size, and the oxygen concentration administered by cannula made estimation of the change in oxygen concentration more complex. Using the conversion formula of Benaron and Benitz,[37] average transformed oxygen concentration for infants on nasal cannula rose from 26% ± 6% before, to 31% ± 11% 24 hours after randomization to the supplemental arm; the average increase was 5% ± 9%. During the same 24-hour period, infants assigned to the conventional arm experienced a change from 36% ± 17% to 32% ± 15% in the infants on a ventilator, CPAP, or hood oxygen, and from 28% ± 10% to 26% ± 11% in the nasal cannula infants. (The 53 conventional and 25 supplemental

* PT indicates prethreshold retinopathy of prematurity.
† Note that in stratum A, infants with bilateral zone I ROP and 1 eye already at threshold or beyond, are categorized as "fellow eye worse than prethreshold."
‡ Plus disease is defined as present when there is posterior pole vascular dilation and tortuosity in at least 2 quadrants. An infant is a plus disease infant if at least 1 study eye has plus disease at baseline. Similarly, an infant is a zone I infant if at least 1 study eye has zone I ROP.
§ "First PT diagnosis" is the date/time of the first examination that showed prethreshold ROP in at least 1 eye that was subsequently confirmed on a second examination.

infants who changed mode of support in 1 direction or the other between nasal cannula and ventilator/CPAP/hood during the first 24 hours after randomization are not included in these calculations.)

Table 4 demonstrates that the distributions of median saturations achieved over the first 2 weeks after randomization were different for the 2 treatment arms. During the first 2 weeks, only 8.0% of median saturations for infants assigned to the conventional arm were in the supplemental range or higher, and

The | symbols indicate the targeted range of saturation values for each arm of the study.
* Each study arm column gives the percentage of all subjects in that column whose median pulse oximetry over the first 2 weeks on study was at the level shown in the left hand column.

only 1.8% of median saturations of infants assigned to supplemental therapy were in the conventional range or lower. Pulse oximetry was recorded from all enrollees for these first 2 weeks of study participation, but beyond this period, as the eyes reached study endpoints, fewer infants remained on equipment to contribute to the accumulating oximetry data. In addition, as some infants in the conventional arm had resolution of their CLD, their saturations became greater than 95% while breathing room air. Figure 4 shows the smoothed overall frequency distribution of the saturation values (1 reading every 40 seconds) for the full period until ophthalmic endpoints for all infants enrolled. These data also include the 81 conventional and 85 supplemental infants who continued to use study equipment at home. Refusal of the parents or guardians to take the study equipment home on the day of discharge was a primary cause of premature cessation of pulse oximetry and study assigned oxygenation, occurring in 26 conventional and 24 supplemental subjects. Many of these families/guardians were willing to continue returning for weekly follow-up examinations, and therefore, were not withdrawn from the study. Comparison of the SES of families who refused equipment, with those that accepted it at home, showed no relationship between SES and refusal of this major home challenge, nor success in remaining in the target zones at home (data not shown).

Ophthalmic Outcome Data

The primary outcome, the proportion of infants with at least 1 eye progressing to confirmed threshold ROP, is shown by treatment arm in Table 5 for all infants and for subgroups of infants defined by baseline ophthalmic characteristics. Overall, 48.5% (145/299) of infants with study endpoints and assigned to the conventional arm progressed to confirmed threshold ROP in at least 1 eye, compared with 40.9%

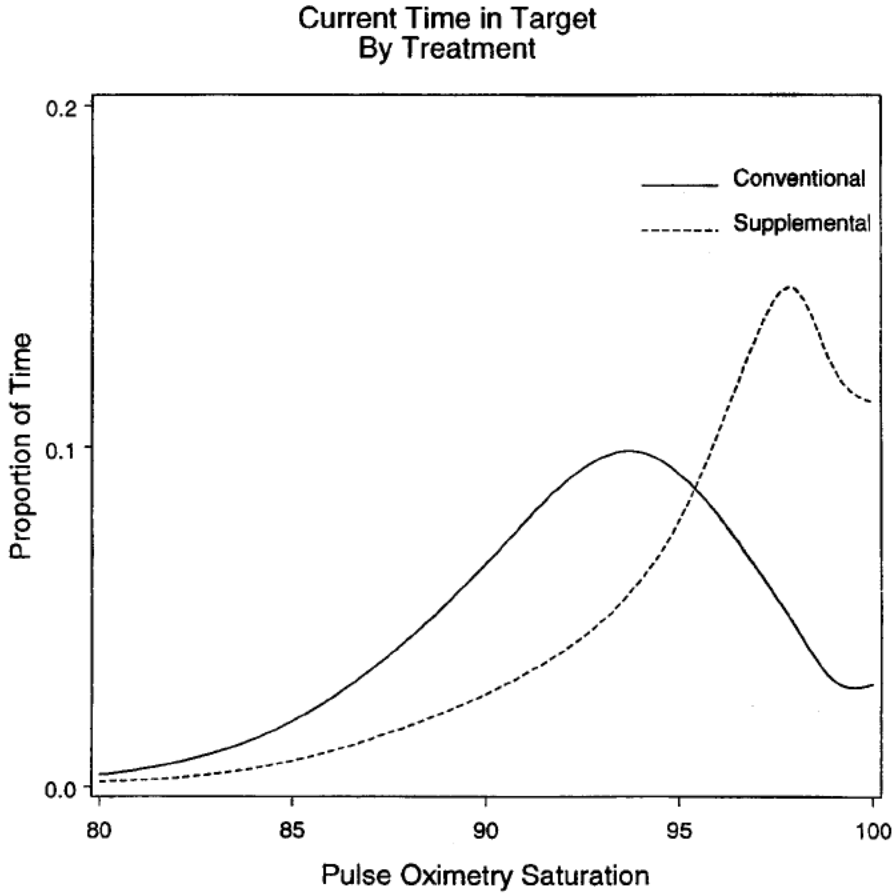

Fig 4. Smoothed frequency distribution of pulse oximetry saturation values for the conventional and supplemental oxygen arms throughout the duration of time on study equipment. Pulse oximetry saturation values were recorded to disk for later analysis once every 40 seconds throughout the time an infant remained on study equipment (range: 2–25 weeks).

* Infant ophthalmic outcomes based on progression of at least 1 study eye to threshold ROP. If an infant entered the study with 1 eye already at threshold or worse, that eye was not a study eye, and the infant's outcome is based on only the study eye.
† "Eye endpoints" means that for that infant, the primary endpoint of either 1) at least 1 eye progressing to threshold, or 2) all study eyes not progressing to threshold is known.
‡ PT indicates prethreshold ROP.
§ "Plus disease infants" are those who have at least 2 quadrants of posterior pole dilation/tortuosity in at least 1 study eye, whereas "non-plus disease infants" have all study eyes with 0 or 1 quadrant of posterior pole dilation/tortuosity.
‖ Mean ± standard deviation.

(122/298) in the supplemental arm. The difference between treatment arms was not significant at the designed 1-tailed α-level of .025, as adjusted for sequential testing. However, the difference was still suggestive, with a 1-tailed P value adjusted for repeated interim analyses of .032.[38] When eyes whose outcomes could be assigned by the Ophthalmic Endpoints Committee were included (31 infants: 15 conventional and 16 supplemental), the progression rates remained similar: 46.2% (145/314) and 39.5% (124/314) for the conventional and supplemental arms, respectively (data not shown).

Analysis by stratum or zone of baseline ROP yielded similar results. The high severity ROP stratum A infants progressed to threshold more frequently than the lower risk stratum B infants (50% vs 43% overall). Higher rates of progression in the conventional arm than in the supplemental arm were observed for both ROP severity strata (55%–46% in stratum A and from 46%–39% in stratum B). When severity was alternatively examined by zone of prethreshold ROP, progression rates also were lower in the supplemental arm (56% vs 49% for zone I and 46% vs 37% for zone II; conventional vs supplemental, respectively); however, none of these differences were statistically significant. In contrast, when progression rates were examined in relation to plus disease, the subgroup analysis revealed a difference. Infants without plus disease in either study eye progressed to threshold 46% versus 32% of the time in the conventional and supplemental arms, respectively (P = .004). When at least 2 quadrants of posterior pole dilation/tortuosity were present in either study eye at baseline, 52% of conventional versus 57% of supplemental infants had at least 1 eye progress to threshold (P = .484).

Adverse outcomes occurred soon after randomization in both groups as shown in Fig 5A, and the elapsed time from study entry to adverse ophthalmic endpoints was slightly longer in the supplemental arm compared with the conventional arm. Mean progression time to threshold disease was 2.4 weeks for eyes in the conventional arm and 2.7 weeks for eyes in the supplemental arm. Eyes with plus disease at study entry progressed to threshold disease most rapidly, at a mean of 1.6 and 2.2 weeks in the conventional arm and supplemental arm, respectively. Eyes without plus disease took somewhat longer (mean of 2.3 weeks and 2.7 weeks, respectively; Table 5). Achieving a favorable outcome took longer (Fig 5B), and the time to full vascularization or zone III vessels on 2 consecutive examinations in eyes

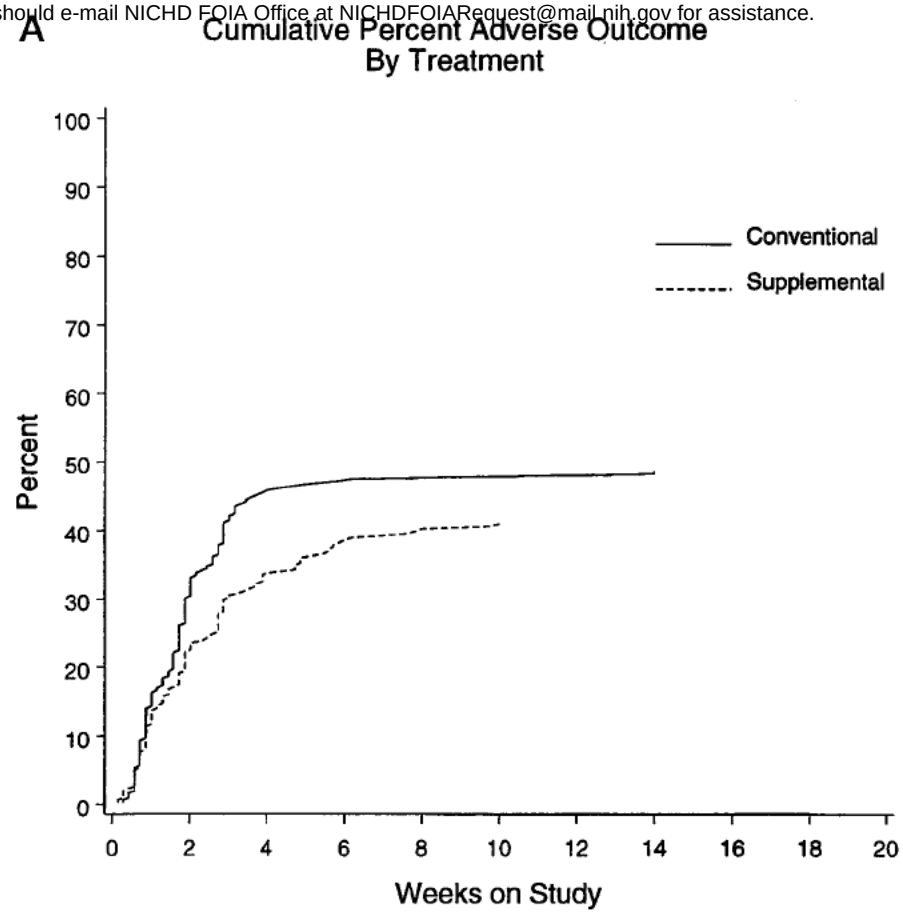

Fig 5. Cumulative rate curves demonstrating the differences in both the proportion and timing of adverse (A) and favorable (B) ophthalmic outcomes by study arm.

without progression to threshold disease occurred in the conventional arm at a mean of 9.0 weeks and in the supplemental arm at a mean of 9.5 weeks. Threshold ROP, when it occurred, was diagnosed at an average PMA of 36.8 weeks (range: 31.6–50.9 weeks) in the conventional arm, and an average of 37.3 weeks' PMA (range: 32.3–45.1 weeks) in the supplemental arm (data not shown in table).

Multiple regression analysis was conducted to adjust for minor variations in baseline characteristics with both simple and complex models. The complex model included treatment assignment, ROP stratum, race, gender, gestational age, small for gestational age status, the baseline pulmonary severity score, plus disease, late versus on-time enrollment, degree of compliance with assigned saturations, interactions of these variables with treatment assignment, and study center. The analysis did not alter the conclusions, but did confirm that both black race (odds ratio [OR]: .44; 95% confidence interval [CI]: .20,.94) and higher gestational age (OR: .80 per week; 95% CI: .66,.98) provide important significant protective effects in reducing the chance of progression of prethreshold ROP to threshold ROP, regardless of treatment arm, while having 2 or more quadrants of posterior pole dilation/tortuosity (plus disease) increased the risk of progression to threshold (OR: 1.71; 95% CI: .95,3.10). In the simplified model, the OR for the supplemental arm after adjustment for ROP risk stratum, plus disease, race, and gestational age was .72 (95% CI: .52,1.01).

Peripheral ablation utilized laser therapy in 93% of treated eyes (73% diode and 20% Argon) and cryotherapy alone in 7%. Four percent of treated eyes received both laser and cryotherapy. Final ophthalmic outcomes based on all study eyes at 3 months' corrected age (or 6 months for 12 conventional and 18 supplemental eyes) revealed adverse outcomes (partial or total retinal detachment, retinal folds, or obstruction of the visual axis) in 4.4% of the study eyes in the conventional and 4.1% in the supplemental arms, and macular ectopia in an additional 3.9% of the study eyes of the conventional arm and 3.9% of the study eyes of the supplemental arm. Among just those eyes that developed threshold ROP and were treated with peripheral surgical ablation, 9.2% in the conventional arm and 13.2% in the supplemental arm had adverse ophthalmic outcomes at 3 to 6 months (excludes macular ectopia that occurred in 6.3% of conventional and 7.7% of supplemental laser/cyro-treated eyes).

Pediatric Outcomes

We hypothesized that infants in the supplemental arm would grow and gain weight faster than infants in the conventional arm, but there were no differences between their growth rates during the initial first 2 weeks, later during the hospitalization period (data not shown), or at 3 months' corrected age (Table 6).

However, markers of CLD severity both during hospitalization and remaining at 3 months' corrected age (50 weeks' PMA) suggest a somewhat worse pulmonary status in the supplemental arm after randomization, although there were no differences in the baseline status measures (Table 2). As shown in Table 6, the conventional arm had fewer infants with 1 or more episodes of pneumonia or CLD exacerbation than did the supplemental arm, 25 (8.5%) versus 38 (13.2%; $P = .066$), and there were also fewer total episodes in the conventional arm (29 vs 51). Using the baseline pulmonary scores to further examine this, infants were divided into higher and lower pulmonary risks at the overall median pulmonary score of .430. The difference in pneumonia/CLD events was confined to the infants with the higher half of the pulmonary scores (10.6% in the conventional arm vs 18.7% in the supplemental arm; $P = .051$) and did not differ among the infants with the lower half of the pulmonary scores (6.5% in the conventional arm vs 6.8% in the supplemental arm; $P = .93$; data not in table). Rehospitalization rates for pulmonary causes (excluding for apnea alone), and death rates from pulmonary causes were similar in the 2 arms (Table 6). However, at the 3-month examination (50 weeks' PMA), more infants in the supplemental arm remained hospitalized (12.7% vs 6.8%; $P = .012$), on oxygen (46.8% vs 37.0%; $P = .020$), and on diuretics (35.8% vs 24.4%; $P = .002$). The proportion of infants who experienced any 1 or more of these adverse pulmonary events by 3 months' corrected age as defined by remaining hospitalized, remaining on study equipment, oxygen, steroids, methylxanthines, or diuretics was significantly higher in the supplemental arm than in the conventional arm (57% vs 46%, respectively; $P = .005$). Regression analysis adjusting for the important baseline covariates of race, ROP severity, gestational age, and pulmonary status did not change the significance of these findings.

Adverse events from sepsis without pneumonia did not differ between the 2 arms, and survival through the 3-month examination was similar (97.8% conventional vs 97.2% supplemental). Mean PMA at discharge for those infants going home was the same in both arms at 41 ± 3 weeks (range: 35–56), and infants in both arms were able to take oral feeds without a gastric tube at the mean PMA of 39 weeks. At the 3-month follow-up examination, developmental levels as assessed by the Revised Parental Denver Questionnaire were similar (equivalent ages = 3.5 ± 1.4 months in the conventional arm vs 3.4 ± 1.4 months in the supplemental arm).

DISCUSSION

These findings demonstrate that supplemental oxygen, as used in this study for prethreshold ROP, did not significantly decrease the proportion of infants who have at least 1 eye progress to threshold ROP, although the differences were close to nominal statistical significance. Using the observed conventional progression rate of 48%, the study has a power of 70% against a 10-percentage point absolute difference, and a power of 98% against a one third reduction, adjusting for the use of repeated interim analyses as described above. The resultant power is lower than expected because the adverse ophthalmic outcome rate in the conventional group was higher than expected.

TABLE 6. Pediatric Outcomes Between Randomization and Three Months' Corrected Age*

	Conventional n = 325	Supplemental n = 324
Event occurring after randomization		
Weight gain over the first 2 wk (g; mean ± standard deviation)	291 ± 137	278 ± 143

* Corrected age indicates months after the date an infant should have been born at full term (3 months' corrected = 52 weeks' PMA).
† Limited to infants who were discharged to home (ie, excludes deaths, loss to follow-up, and those remaining hospitalized at the 3-month examination).
‡ Excludes 16 conventional and 33 supplemental infants who were not yet feeding by mouth by 50 weeks' PMA, 2 conventional and 7 supplemental infants who died before oral feeds, and 6 conventional and 7 supplemental infants with incomplete data. Oral feeds means that the infant was taking all enteral feedings by nipple (bottle or breast).
§ Excludes 30 conventional and 36 supplemental infants recruited early in the trial for whom these data were not collected.
‖ The 3-month corrected age window was a target of 12 ± 2 weeks after due date, or 50 to 54 weeks' PMA. Outcomes are reported as of 50 weeks' PMA to permit comparisons as some infants were examined late in the window or outside this window.
¶ Values exclude 31 infants with missing data at 50 weeks' PMA attributable to loss to follow-up (14 conventional and 17 supplemental).
# Number of infants, and percent of all enrollees represented by any 1 or more of the 3-month events.
** R-PDQ indicates the Revised Parental Denver Questionnaire.[26]

In STOP-ROP, the observed rate of progression from prethreshold to threshold (48%) in the conventional arm is higher than reported in the CRYO-ROP study (33%) for a number of reasons that can be identified. The eligibility criteria for STOP-ROP excluded nearly half of the infants who would have been included in the CRYO-ROP study, and these were the ones that did not require oxygen and had less severe lung disease at the time of prethreshold ROP. The STOP-ROP enrollees had lower birth weights than the CRYO-ROP infants (726 g in STOP-ROP vs ~850 g for CRYO-ROP prethreshold).[1] During the CRYO-ROP study, borderline threshold cases were judged as not threshold, to avoid treating eyes with an unproven intervention. Because peripheral ablation has been demonstrated to be effective for threshold ROP, this is no longer true, and as in clinical practice, the STOP-ROP study judged in favor of the diagnosis of threshold disease in borderline cases. Finally, the differences in the STOP-ROP definition of threshold ROP in zone I (see Table 1) would result in more infants being diagnosed with threshold ROP during the STOP-ROP trial.

The STOP-ROP results differ from the 2 smaller case series in the literature in which supplemental oxygen for infants with prethreshold ROP was associated with a high regression rate of prethreshold ROP without the need for ablative retinal surgery.[28,29] Some of the possible explanations are differences in patient selection, level of oxygen administration, timing of the intervention, and use of historical controls in the case series. Infants in these case series may have had milder ROP than those enrolled in STOP-ROP, and the effect of that would be higher progression rates in STOP-ROP. The average birth weight of the infants in that series was 814 g, heavier than the 726-g average birth weight of infants enrolled in STOP-ROP, and therefore, at lower risk for severe ROP. In the Gaynon et al[28] series, if infants were mostly detected as having pretheshold ROP before developing plus disease, the findings in that series and the subgroup of infants in STOP-ROP without plus disease would be more consistent. Large differences in reported improvements between historically controlled case series and randomized trials are well recognized and are usually attributed to changes in several aspects of medical care over time, as well as patient selection. STOP-ROP expended considerable effort to maximize the time infants were in their targeted ranges of saturation and not at saturation levels of 100%. In contrast, however, the saturation targets were "a minimum of 99%" in the Gaynon et al study,[28] and "a minimum of 98%" in the Seiberth et

al report.[38] Thus, infants in those 2 series probably had higher average saturation levels than the STOP-ROP supplemental group. To compare the target range of the supplemental arm in STOP-ROP as measured by the Ohmeda 3740 oximeter with these other 2 studies, it could be argued that 1.6 saturation points should be added to the STOP-ROP range to make the saturation monitor readings equivalent. If this is done, the STOP-ROP supplemental range becomes 97.6% to 100% saturation, even closer to the reported series and, therefore, not an explanation of differences.

Another alternative explanation may be in the timing of treatment. If immediate application of the supplemental oxygen at prethreshold diagnosis would provide maximum benefit, it could be argued that use in standard practice would result in earlier and possibly more effective treatment of eyes with prethreshold ROP. Gaynon reports (D. L. Phelps, personal communication, October 1999) that ROP screening was performed at weekly intervals in their series, which could be expected to reduce the number of infants reaching plus disease before beginning oxygen treatment. Screening examinations before prethreshold identification were usually performed every 2 weeks in the STOP-ROP centers, consistent with the AAP recommendations. In addition, the process of obtaining both an independent confirming examination and informed consent of the family or guardians resulted in delays between the first time that prethreshold ROP was observed and the start of the study intervention. In approximately one quarter of the cases, this was >48 hours.

Oxygen requirements go up by ~5 to 9 percentage points when changing to supplemental oxygen from the conventional range, emphasizing that infants truly receive more oxygen when assigned to the supplemental arm. We had not expected that pulmonary events of pneumonia and/or CLD exacerbations were going to be 1.8 times more likely to occur in the supplemental arm. The absolute increase in acute pulmonary events of 7.3% gives a number-needed-to-treat calculation of 1 more pneumonia/CLD episode for each 13.7 infants treated with supplemental oxygen. The ROP progression data give a number-needed-to-treat of 13.2 infants to prevent 1 case of progression to threshold ROP. By this analysis, one could expect ~1 episode of pneumonia/CLD exacerbation for each case of peripheral ablative surgery that might be prevented. That might be regarded as a reasonable trade-off by most neonatologists and ophthalmologists, but the condition of the infants at 3 months' corrected age must also be considered. At that time, 97% of subjects were off the study assigned treatments, and those in the supplemental arm continued to need more oxygen and diuretics, and a greater number remained hospitalized. Our data suggest that the magnitude of any benefit from supplemental oxygen in reducing the need for surgery is likely to be on the order of 7% to 14%, with no reduction in the number of retinal detachments. The potential long-term advantage of avoiding peripheral ablative surgery for ROP is unknown, but to the extent long-term side effects might occur, even a small reduction in surgery rates may be of value. The potential long-term effects, both of costs and to the families, of prolonging hospitalization from worsened lung disease also should be considered.

Our original hypothesis was not only that supplemental oxygen would prove beneficial for the eyes of infants with prethreshold ROP whose pulse oximetry in room air is <94%, but in addition, that it would be beneficial for CLD, resulting in better growth and lower pulmonary vascular resistance.[39,40] However, Supplemental oxygen at a target range of 96% to 99% saturation seemed to have deleterious effects on CLD in some infants, with no change in growth or neuromotor development. Previous reports of an improvement in weight gain and resolution of cor pulmonale with oxygen supplementation could be explained if saturation levels in the control infants of those studies were even lower than the STOP-ROP conventional range. This is certainly possible, because those reports date from periods preceding the routine availability of continuous pulse oximetry. Fortunately, others are investigating this question in a carefully controlled randomized trial in Australia. The Benefits of Oxygen Saturation Targeting Trial is currently enrolling infants in a test of the safety and efficacy of supplemental oxygen for infants with CLD. ROP is not an entry criterion in that study, but will be examined as a secondary outcome (D. Henderson-Smart, personal communication, 1999).

These results provide valuable data for the clinician. The STOP-ROP data clearly demonstrate that oxygen, at saturation levels of 96% to 99% does not increase the severity of ROP in the eyes of infants with prethreshold ROP, even in the 123 eyes with ROP of less than pretheshold severity at randomization. There are no data, however, to suggest that the higher saturation levels are safe for the early immature eye that does not yet have established ROP. The reported data apply only to infants who are well beyond the initial weeks after birth and must not be interpreted as showing safety of supplemental levels of oxygen at younger ages.

The present study does not rule out a potential small reduction in the rate of ROP progression with supplemental oxygen, and a subgroup analysis suggests that supplemental oxygen, as used in this study, may be more effective in pretheshold ROP without plus disease. However, secondary analyses, not prespecified, must be cautiously interpreted and require additional study. The predictive value of various possible definitions of prethreshold ROP have not been systematically studied and reported but could prove very important and should be investigated. The data show a modest deleterious effect of supplemental oxygen on CLD in some infants with more severe lung disease at baseline. Therefore, clinicians must consider which patients might tolerate the added pulmonary risk of supplemental oxygen as a therapeutic intervention for their ROP. If an infant requires saturations of 96% to 99% for cardiopulmonary reasons, fear about causing worse ROP is not a reason to withhold the oxygen. Results from other studies, such as the Benefits of Oxygen Satura-

tion Targeting Trial, may help further our understanding of the effects of supplemental oxygen in infants with CLD.

ACKNOWLEDGMENTS

STOP-ROP was supported by grants from the National Eye Institute, the National Institute of Child Health and Human Development, the National Institute of Nursing Research, several National Institutes of Health General Clinical Research Centers, and local funding sources at many centers. These included: in Rochester, NY, The Delta Gamma Sorority, the Rhea and Raymond White donation, and Research to Prevent Blindness; Boston, MA, support for home oxygen provided by Chartwell Home Therapy, and the New England Medical Center received support from the National Institutes of Health General Clinical Research Center Grant M01-RR00054; and Stanford University received additional support from National Institutes of Health RR 00 070 and National Institutes of Health HD 27 880.

We are indebted to the families who allowed their infants to participate in the STOP-ROP trial, and the dedicated and patient nurses in 71 newborn intensive care units who worked so hard to keep infants within the study target ranges. The Ohmeda Corporation kindly donated the pulse oximeters, and training on their use for all the study centers. We thank Velma Dobson, PhD, for her critical review of the draft manuscript, and Randy Taft of ProFox, Inc, for helping us to develop the laptop computer program that provided feedback on the oximetry.

APPENDIX: THE STOP-ROP PARTICIPATING CENTERS AND MAJOR COMMITTEES

Permanent Executive Committee

Chair: Dale L. Phelps, MD; Members: Anne Lindblad, PhD; J. David Bradford, MD; Nancy E. Wood, CCRA; Neal L. Oden, PhD; Cynthia Cole, MD; Brenda MacKinnon, RNC; Anita Yaffe, MSN, MPH; Donald F. Everett, MA; Linda Wright, MD; Cara Krulewitch, CNM, PhD; Additional Writing Committee Members: Beverly S. Brozanski, MD; Terri Young, MD; Mark Scott, MD

Data and Safety and Monitoring Committee

Chair: Barbara S. Hawkins, PhD; Members: Colin B. Begg, PhD; Edward F. Bell, MD; Edward G. Buckley, MD; William W. Hay, MD; Burton J. Kushner, MD; Linda Snouck-Hurgronje, RN, MS; Carol R. Taylor, CSFN

Data Coordinating Center

Principal Investigator: Neal L. Oden, PhD; Anne S. Lindblad, PhD; Co-investigators: Christine Bachy, BS; Stuart H. Berlin, BS; Diane Brandt, BS; Marsha Guzzey, MLT; Linda Henson; Bernadette Jolles, MA; Elaine Stine; Carol Thomas-Sharp, MS, RN; Judith Van Lare; Anita Yaffe, MSN, MPH

Boston Consortium: New England Medical Center, Boston City Hospital, Children's Hospital, Brigham and Women's Hospital, Beth Israel Deaconess Medical Center, Beverly Hospital, Salem Hospital, South Shore Hospital, Good Samaritan Hospital, Newton Wellesley Hospital, Winchester Hospital, Lowell General Hospital. Principal Investigator: Cynthia Cole, MD; Jane Stewart, MD; Co-investigators: Brenda MacKinnon, RNC; Tracey Alexander, RN; Charles Anderson, MD; Mohammed Ashrafzadeh, MD; Caroline Baumal, MD; Amita Bhatt, MD; Richard Blocker, MD; Elizabeth Brown, MD; Mario Cordova, MD; Mark P. Dacey, MD; Jay Duker, MD; Janine Eagle, MD; Eric Eichenwald, MD; Christy Faherty, RN; Alan Fujii, MD; James Gray, MD; Mary Elizabeth Hartnett, MD; Karen Harvey-Wilkes, MD; Julie Hetrick, RN; Mark Hughes, MD; Michael Ip, MD; Susan Izatt, MD; Robert Lacy, MD; Joseph Levy, MD; Thomas Margolis, MD; Karen R. McAlmon, MD; O'Ine McCabe, MD; Maryanne Moore, RN; John Niffenegger, MD; Sam Nikou, MD; Robert Petersen, MD; Kevin Petit, MD; Eric A. Pierce, MD; Bill Powers, MD; Maureen Pursley, RN; Elias Reichel, MD; Leon Remis, MD; Mark Rivellese, MD; Barbara Ann Shephard, MD; Jeffrey Sorkin, MD; Ann Stark, MD; Susan Struzik, RN; Tai Tran, MD; Deborah K. VanderVeen, MD; Patricia Vreeland, RT; Richard Wilker, MD; John Wright, MD; Vivian Kim, MD; Vinay Desai, MD; Bryan Rutledge, MD

Columbus: Columbus Childrens Hospital, Ohio State University, Grant Medical Center, Mount Carmel Medical Center. Principal Investigator: Richard E. McClead, MD; Co-investigators: Rae Fellows, MEd; Marci Biel, RNC; Don L. Bremer, MD; Rosalind Maddox, RRT; Brenda Mann, RNC, BSN; Mary Lou McGregor, MD; Christina Nye, MD; Phyllis Peterman, RT; Gary L. Rogers, MD; Ellen M. Rosenberg, MD; John Seguin, MD; Sue Stephen, RN, MS; Craig W. Anderson, MD; Leandro Cordero, MD

Philadelphia: Thomas Jefferson University, Childrens Hospital of Philadelphia, Hospital of the University of Pennsylvania, Albert Einstein Medical Center, Medical Center of Delaware. Principal Investigator: Alan R. Spitzer, MD; Co-investigators: Linda Corcoran, RN; Jim Cullen, RN; Josh Fosnot, BA; Shobhana Desai, MD; Jane Fricko, RN; Joan Giannetta, RN; Mary Catherine Harris, MD; David Hepps, BA; Richard Hertle, MD; Bill Holt, RTT, RN; Kathy Leef; J. Arch McNamara, MD; Dennis Miller, BA; Kathy Mooney, RN; Michael Naidoff, MD; Jeanette R Pleasure, MD; Rachael Porat, MD; Graham Quinn, MD; Terri Saunders, David Schaffer, MD; Michael Spear, MD; Susan Spinner, MSN; William Tasman, MD; James Franklin Vander, MD; Martin Wilson, MD; Sharon Zirin, RN

University of Arkansas: Arkansas Childrens Hospital, University of Arkansas. Principal Investigator: J. David Bradford, MD; Co-investigators: Peggy Ables, RN; Cynthia Bonner, MD; Michael Brodsky, MD; Erin Davis, RN, NNP; Kristie Frost, RN, NNP; Richard W. Hall, MD; Richard Harper, MD; Billy R. Thomas, MD

University of Louisville: University of Louisville, Nortons Hospital, Kosair Childrens Hospital. Principal Investigator: Charles C. Barr, MD; Co-investigators: David Adamkin, MD; Craig H.Douglas, MD; Peggy H. Fishman, MD; Nan Hamlyn-Forti, BSN; Tony Hilbert, John Roberts, MD; Greg Whittington, PsyS;. Judy Wright, BSN

Brown University. Principal Investigator: William Oh, MD; Co-investigators: Nancy Adams, RN; Dawn Andrews, RN; Arthur I. Geltzer, MD; Angelita Hensman, RN; Sue Philo-Heroux, RN; Robert W. Rothstein, MD; Lori Snady-McCoy, MD

Emory University: Crawford Long Hospital, Grady Memorial Hospital. Principal Investigator: Barbara Stoll, MD; Co-investigators: Antonio Capone, MD; Ann D. Critz, MD; Arlene V. Drack, MD; Cathy H. Goulding, RN; Daniel F. Martin, MD; Timothy W. Olsen, MD; Paul Sternberg, MD; Mary Beth White, RN

Indiana University: James Whitcomb Riley Hospital for Children, Wishard Memorial Hospital, Indiana University Hospital, Methodist Hospital. Principal Investigator: James A. Lemons, MD; Co-investigators: Dee Dee Appel, RN, Scott C, Denne, MD; Forest Ellis, MD; Eugene Helveston, MD; Ann McKee, RN; Daniel Neely, MD; David Plager, MD; Co-principal Investigator: Derek Sprunger, MD; Dianne Wilson, RN; Leslie Dawn Wright, RN

Stanford University: Stanford University Medical Center. Principal Investigator: David K. Stevenson, MD; Co-investigators: Deborah M. Alcorn, MD; M. Bethany Ball, BS, CCRC; Debora Bone, RN; Barry E. Fleisher, MD; Michael W. Gaynon, MD; William V. Good, MD; Dorothy Inguillo, RN

University of Cincinnati: University of Cincinnati, Childrens Hospital of Cincinnati, E. H. Crump Hospital. Principal Investigator: Edward Donovan, MD; Co-investigators: Miles Burke, MD; Susan Carden, MBBS, FRACO, FRACS; Sara Colegate, RN; William V. Good, MD; Cathy Grisby, RN; Becky Hitchcock, RT; Robert K. Hutchins, MD; Arif O. Khan, MD; Uma Kotagal, MD; Marcia Mersmann, RN; Karen Munson, RN; Rees W. Sheppard, MD; Constance West, MD

University of Tennessee: Principal Investigator: Sheldon Korones, MD; Co-investigators: Henrietta Bada, MD; Sid Borirak, MD; Beth Brewer, RN; Gail Camp, RN; Shelia Dempsey, RN; Chris Devine, MD; Alan Downie, MD; David W. Faber, MD; Sandra Grimes, RN; Richard Hairston, MD; Barbara Hensley, RN; Tina Hudson, RN, BSN; Vicki Johnson, RN; Adam Katz, MD; Laura Manejwala, RN; Joseph Schwartz, MD; Kent Zocchi, MD; Maurice Landers, MD; Brian Jewart, MD

University of Texas: University of Texas, St. Paul Hospital. Principal Investigator: Jon E. Tyson, MD; Kathleen Kennedy, MD; Co-investigators: Rajiv Anand, MD; Gay Hensley, RN; David Metrikin, MD; Rand Spencer, MD; Sherry Warner, RN; David Weakley, MD; Charles A. Wilson, MD; Jeannette Burchfield, RN

Wayne State University: Childrens Hospital of Michigan, Hutzel Hospital, Grace Hospital, St. Johns Hospital. Principal Investigator: Mary Bedard, MD; Co-investigators: John D. Baker, MD; Rebecca Bara, RN; Renato Casabar, MD; Keh-Chyang Liang, MD; William Lucas, MD; Geraldine Muran, RN; Edward O'Malley,

MD; James L. Pulkin, MD; John Roarty, MD; Seetha Shankaran, MD; Michael Trese, MD

Yale University: Childrens Hospital at Yale New Haven. Principal Investigator: Richard A. Ehrenkranz, MD; Co-investigators: Christine Bartley, RN; Patricia A. Gettner, RN; Gina Juliano, RN; Monica Konstantino, RN; Susan Moylan, RN; Steven M. Peterec, MD; Jonathan Sears, MD; Elaine Sherwonit, RN; Kathleen Stoessel, MD

Kapiolani Medical Center: Kapiolani Medical Center. Principal Investigator: David Easa, MD; John H. Drouilhet, MD; Co-investigators: Kenneth Ash, MD; Neal Atebara, MD; V. Balaraman, MBBS; Laurie Debuque, RN; John Douglas, MD; Emily Fritz, RN; Carol Hirai, MD; Lynn Iwamoto, MD; Susan Kau, RNC; Gregg Kokame, MD; Peggy Liao, MD; Sherry Loo, MD; Joan Meister, MD; Daniel Murai, MD; Kenneth T. Nakamura, MD; Mary Elaine Patrinos, MD; Sue Pelke, RN; Gail Post, RN; Sneha Sood, MD; Donald A. Sroat, MD; Larry Tinsley, MD; Byron Wong, MD; Vernon Wong, MD

Magee-Womens Hospital: Magee Womens Hospital, West Penn Hospital, Transitional Infant Care. Principal Investigator: Beverly S. Brozanski, MD; Kenneth P. Cheng, MD; Co-investigators: Robert L. Bergren, MD; Albert W. Biglan, MD; John S Davis, MD; Bernard Doft, MD; Marc E. Hoffman, DO, FACS; Judith Jones, BSN, RNC; Giovanni Laneri, MD; Louis A. Lobes, MD; Karl R. Olsen, MD; Jeffrey Rinkoff, MD; Roger L. Vazquez, MD

University of Rochester (Study Headquarters): Childrens' Hospital at Strong. Principal Investigator: Dale L. Phelps, MD; Co-investigators: Nancy Wood, CCRA; Kathleen Brown, RN; Laurie Mansfield, BS; Gary D. Markowitz, MD; Ernest Guillet, MD; Jan Morris, RN; Kathy Nicoletta, RN; Steven Rose, MD; Robert Sinkin, MD; Donald Tingley, MD; Robert Vanderlinde, MD; Scott Shutts, BA; Childrens Hospital of Buffalo; Co-principal investigator: Vivien Carrion, MD; Co-investigators: James Cummings, MD; Steven Awner, MD; Diane Marano, RN; Scott Olitsky, MD; James Reynolds, MD; Marcia Terpin, RN

Tulane University: Tulane University Medical Center, Charity Hospital. Principal Investigator: Robert Gordon, MD; Co-investigators: James G. Diamond, MD; Beverly Hasty-Voelkel, RN; Debbie Neff, LPN; Jane Reynolds, MD; Thomas G. Storch, MD

SUNY Stonybrook: University Hospital at Stonybrook, Long Island Jewish Medical Center. Principal Investigator: Pamela A. Weber, MD; Co-investigators: Michael J. Barondes, MD; Lyle Browne, MD; Adriann Combs, RNC; Fahdy Elbaba, MD; Kerry Gallagher, RN; C. Corina Gerontis, MD; Katherine King, MD; Leonard Kleinman, MD; Sylvia Kodsi, MD; Edmund LaGamma, MD; Philip Lipsitz, MD; Maury Marmor, MD; Rose Vega McGovern, RN; Barbara Wilkens, RN

Akron Childrens Hospital: Childrens Hospital Medical Center of Akron. Principal Investigator: Frank W. Kokomoor, MD; Co-investigators: Joyce E. Burton, RN; Mary K. Enlow, MD; Harriet J. Feick, MD; Clair E. Jaberg, Ann Kelley, RN; Michael J. Kisak; Anthony J. Locastro, MD; Charles A. Peter, MD; Thomas J. Tsai, MD

Chicago Consortium: University of Illinois at Chicago, Loyola University and Medical Center, Childrens Memorial Hospital, Rush-Presbyterian-St. Lukes Medical Center, Cook County Hospital, Illinois Masonic Medical Center, Christ Hospital and Medical Center, Northwestern University, Michael Reese Hospital. Principal Investigator: Michael J. Shapiro, MD; Co-principal investigator (1994–1995): Jonathan M. Holmes, MD; Co-investigators: Ismail Abbasi, MD; Sikander Adeni, MD; Otto Aldana, MD; Daniel Alter, MD; Kathryn A. Annerino, RN; Subash Arora, MD; Herbert Becker, MD; Rama Bhat, MD; Harold R. Bigger, MD; Wutthichai Bunjapamai, MD; Geetha Cattamanchi, MD; Jack A. Cohen, MD; James W. Collins, MD; Cathleen M. Cronin, MD; Mark J. Daily, MD; Cheryl L. Davis, MD; Felipe De Alba, MD; Steven A. DeKowski, MD; Ruth B. Deddish, MD; Angela Dorton, RN; Philip B. Dray, MD; Lisa A. Duffner; Linda Dusek, RN; David S. Dyer, MD; Minyuen C. Enger, MD; Joel B. Fisher, MD; Antonio Fiumara, MD; Steven Friedlander, MD; Vivek Ghai, MD; Jon P. Gieser, MD; Richard G. Gieser, MD; Mark J. Greenwald, MD; Navajeeva Ravi Gunawardene, MD; Balagi Gupta, MD; Nancy Guyer, RN; Amy M. Hennessy, RN; Gonzalo Hernandez, MD; David C. Hyde, MD; Michell Illian, RN; Renu Jain, MD; Robert D. Jansen, MD; Lawrence M. Kaufman, MD; Patricia Kling, RN; Ron M. Kurtz, MD; Catherine Lai; Mary Jo Leamy, RN; Aleyamma Lukose, RN; Alice T. Lyon, MD; Mathew MacCumber, MD; Kristine M. McCulloch, MD; James F. McDonnell, MD; Carol Menner, MD; Marilyn B. Mets, MD; Dietra D. Millard, MD; Marilyn T. Miller, MD; Michael E. Mockovak, MD; Amy Morose, RN; Meg Naber, RNC, MSN; Pamela Nitz, RN; Edward S. Ogata, MD; Khozema A. Palanpurwala, MD; Cynthia A. Paulin, RN; John Payton, MD; Brian A. Phillpotts, MD; Suma Pyati, MD; Tonse N. K. Raju, MD; Kenneth I. Resnick, MD; Bernadine Rupar, COT; Christine Sajous, MD; Nydia E. Santiago; Brenda Dunseath-Shuman, RNC; Rebecca A. Simmons, MD; Anjali Singh; Debra L. Skopec, RN; Marcus J. Solomon, MD; Margaret A. Squires, LPN; Benjamin H. Ticho, MD; Ushanalini Vasan, MD; Dharmapuri Vidyasagar, MD; Stephen N. Wall, MD; Aaron B. Weinberg, MD; David V. Weinberg, MD; Angela Wilks, MD; Evangelia Zikos, MD

Oregon Consortium: Legacy Emanuel Childrens Hospital, Doernbecher Memorial Hospital for Children. Principal Investigator: Raul C. Banagale, MD; Co-investigators: Aazy Arthur Aaby, MD; Sandra A. Banta-Wright, RNC; Louise M. Baxter, MD; Jodeanne K. Bellant, MD; Gerda Benda, MD; Nancy D. Binder, MD, PhD; William J. Brown, MD; Larry Cheldelin, MD; Laurie Christensen, MD; Victoria DeVito, MD; Nancy G. Dolphin, RN, BSN; Sharon Dunham, RN; Al Edwards, MD; Joseph T. Gilhooly, MD; Shawn Goodman, MD; Robert Huston, MD; Patrick K. Lewallen, MD; John McDonald, MD; Rebecca Mischel, MD; David L. Murphy, MD; Valerie Newman, MD; Craig M. Novack, MD; Stephanie Owen, RN; Earl A. Palmer, MD; De-Ann M. Pillers, MD, PhD; Michael Powers, MD; Steven Rimmer, MD; Joseph Robertson, MD; Sue Ann Smith, MD; Andrea C. Tongue, MD; Linda D. Wallen, MD; David T. Wheeler, MD

Sheridan Childrens Healthcare Services: Plantation General Hospital, Joe DiMaggio Childrens Hospital. Principal Investigator: Mitchell E. Stern, MD; Co-investigators: Richard Auerbach; Mark Dorfman, MD; Jose G. Poliak, MD; Brenda Weinstein, RNC; Kay Wigton, RNC, MSN

University of Maryland: University of Maryland Medical Center, Mercy Medical Center, St Agnes Hospital. Principal Investigator: Mark W. Preslan, MD; Ira H. Gewolb, MD; Co-investigators: Begona Aristimuno, MD; Howard J. Birenbaum, MD; Barbara Bristol, RN; Susan Dulkerian, MD; Ronald L. Gutberlet, MD; Kelly Hutcheson, MD; Timothy W. Palmer, MD; Michael X. Repka, MD; Christianne Schoedel, MD; Scott Steidl, MD; Tamara Tanbusch, RN, BSN; Joanne Waeltermann, MD; Randall V. Wong, MD

Vanderbilt University: Vanderbilt University Medical Center. Principal Investigator: Stephen S. Feman, MD; Co-investigator: Robert B. Cotton, MD; Sean Donahue, MD; David A. Johnson, MD; Amy B. Law, RN; Robbin B. Sinatra, MD; Steven D. Steele, RN; William F. Walsh, MD

Jacksonville Consortium: University Medical Center, Baptist Medical Center. Principal Investigator: James Kirk, DO; Michael W. Stewart, MD; Co-investigators: James P. Bolling, MD; J. Shepard Bryan, MD; Vickie L. Chapman-Shaw, ARNP, RNC; R. Donald Garrison, MD; Robert W. Hered, MD; Judy Higgison; Lee R. Hunter, MD; Fred H. Lambrou, MD; Laurie A. Ott, RNC, MSN; Alexander E. Pogrebniak, MD; Mary Self, RN; Vicki Vargo, Arthur J. Vaughn, MD; Julie Young, RN

Minnesota Consortium: Fairview University Medical Center-Hennepin County Medical Center, Childrens Health Care-Minneapolis. Principal Investigator: Terri L. Young, MD; Co-investigators: Cathryn S. Angel, MD; Catherine M. Bendel, MD; David Brasel, MD; Kim Chisholm, RN; Stephen Christiansen, MD; Raul F. Cifuentes, MD; Sally M. Cook, BA; James E. Egbert, MD; Rolf R. Engel, MD; John Fangman, MD; Pat Geier, RN, NNP; Ann Marie Holleschau; Alvina M. Janda, MD; Molly Maxwell, RN, BSN; Carol Miller, RN; Marla M. Mills, RN, MSN, CPNP; Kimberly A. Neely, MD; Ted Pier, MD; Kristin S. Rebertus, RN, NNP; W. Pringle Rodman, MD; C. Gail Summers, MD; Nancy L. Trower, RN, NNP

Oklahoma Consortium: Childrens Hospital of Oklahoma, Mercy Medical Center. Principal Investigator: Mary Anne McCaffree, MD; Mark Scott, MD; Co-investigators: Reagan H. Bradford, MD; Randolph D. Brown, MD; Jana Butcher, RN; Edward Co, MD; Karen Corff, MS, NNP; Annette Grellner, RN; Larry Henson; Lora King; Sylvia Lopez, MD; Janie M. Shofner, COA, CCRA; Theodore A. Tolentino, MD; Anne Godart Wlodaver, MD

Childrens Medical Center of Northwest Ohio: Principal Investigator: Malini Satish, MD; Co-investigators: Brian Bradley, MD; Charles K. Dabbs, MD; Vicky M. Gall, RNC, NNP; Karen Gunther, RNC, NNP; J. Gregory Rosenthal, MD; Beatrice Troxell, RNC, NNP

Cook Institute for Research and Education: Spectrum Health: DeVos Children's Hospital, Blodgett Hospital. Principal Investigator: Patrick J. Droste, MD; Co-investigators: Carmen Alexander,

RN, BSN; Ed Beaumont, MD; Louis Glazer, MD; Lynnette Johnson, RN; Alan R. Margherio, MD; Sue Mesecar, BSN, NNP; C. E. Pippenger, PhD; Michael Spencer, MD; Gerard VanWesop, MD; Charles Winslow, MD

Subject: RE: SUPPORT call for the NRN, Wed, Nov 30, 9:30-10:30am ET (6:30-7:30am PT)
Date: Wednesday, November 30, 2005 1:54:57 PM

Neil and Rose,

Sorry I missed the call - I'm in the NICU this week. Bob Dillard and I discussed Neil's proposed changes in response to the DSMC concerns and agree with what he's proposed.

Thank you,

Mike

---

Thanks for this excellent work Neil. I spent some time making editorial changes that I believe will facilitate the DSMCs review of this comprehensive and complex document.
(I guess I am still in book editor mode!) Hope this helps.
Michele

Subject: Response to DSMC Steering Nov 30 05

HI,
Attached is the final response to the DSMC as discussed on the phone this morning. Please review this and let me know by tomorrow (December 1) evening if this is acceptable to you and your site.
A special thanks to Neil and RTI (Marie and Abhik) for all the time and effort that has been put into this project!!
Rose
<<Response to DSMC Steering Nov 30 05.doc>>

In response to the comments and concerns of the DSMC, the SUPPORT committee held a conference call Monday Nov 28th at 10:00 to 1130AM to prepare a response.

- The DSMC made the following 2 comments in their letter regarding the SUPPORT trial. This was generated after they reviewed the oximeter data, which was corrected back to actual SpO2 values from the altered values displayed at the bedside:

1. There is a significant safety and exposure issue for the infants in the high saturation treatment group because an unacceptably high proportion of time was spent by these study subjects in the >95% range

2. There is a futility concern for this arm of the trial in that there does not appear to be substantial separation between the two high and low saturation treatment groups, and the babies are not being kept in the target range the appropriate amount of time in order to meaningfully test the oxygen saturation intervention as originally designed.

Based on these two issues, the consensus of the Committee was to recommend stopping the oxygen saturation arms of the SUPPORT trial due to safety and futility concerns.

We have responded to each of these concerns and our responses are detailed below

Response to Issue Number 1

We appreciate the concern expressed by the DSMC regarding a potential safety issue secondary to durations of SpO2 values > 95%.

1. To date there are no prospective data which define the SpO2s experienced by the ELBW infant from birth as part of usual clinical care. Because no published studies have evaluated the effects of different target SpO2 ranges on important outcomes, this was one of the principle reasons for the design and conduct of the SUPPORT trial.

2. A number of studies have evaluated different alarm limits, but have not reported the actual durations of SpO2 in the various ranges. Nghiem et al in a PAS abstract this year reported that nurses caring for ELBW infants believe that an acceptable oxygen saturation range should include higher upper limits than specified by current policy (Nghiem et al, Nursing Opinions and Practices of Oxygenation in Prematures: The NOPOP Study PAS #3415, 2005). The study by Hagadorn reported as a late breaker at the PAS this year (Hagadorn et al, Actual vs Intended Pulse Oxygen Saturation (SpO2) in Infants <28 Weeks Gestation. PAS 2005, Attached) did report on the experience of monitoring the actual SpO2 for 72 hours in the first 4 weeks of life in 72 ELBW infants. They reported that the "lower limits of intended ranges at study centers varied between 83-92%, upper limits 92-98%. Infants were monitored for a median of 70 hours (25th-75th percentiles 67-71 hr) during each week. Overall median SpO2 for infants on supplemental O2 during the first 4 weeks was 95% (25th-75th percentiles 91-97%; range of study center medians 91-96%). Centers ranged between 16-71% compliance with their individual intended SpO2 range. Most noncompliance was above intended range." In comparing the SUPPORT data

Formatted

Formatted

Formatted

evaluated to date by the DSMC, it is of interest that the mean SpO2 in the 2 Oximeter arms is 90% and 92%, with medians of 92% and 94%, all of which are below that reported by Hagadorn et al (median=95).

The 2 other relevant trials, STOP-ROP and BOOST, both enrolled infants at about 32 weeks PCA, and maintained 2 levels of SpO2, 89% to 94% and 91-94% versus 95% to 98% and 96% to 99%, by administration of oxygen. These studies achieved reasonable separation, but did demonstrate substantial overlap of the intended ranges. It is important to note that these studies were testing two ranges both of which were higher than the lower range of the SUPPORT trial (85% to 89%) and were treating infants who, for the most part, had recovered from their acute disease. In the BOOST trial 70% of the enrolled infants were < 28 weeks of age at birth (all of SUPPORT is < 28 weeks), 32 weeks postmenstrual age (PMA), and required oxygen at enrollment (Askie et al, New England Journal of Medicine. 2003; 349(10):959-967). The STOP-ROP trial enrolled infants with pre-threshold ROP at a PMA of 35.4 + 2.5 weeks of age (Phelps et al, Pediatrics. 2000; 105(2):295-310). These trials then gave the higher SpO2 range infants additional oxygen to increase their SpO2 to the desired range. STOP-ROP reported that the infants in the high range had an SpO2 > 95% for > 97% of the monitored time. These studies found an overall increase in pulmonary morbidity in the higher SpO2 range infants.

Examination of oximeter data from one ~~if~~ of the NRN sites (Case Western, Walsh et al) obtained for an ongoing study evaluating infants similar to those enrolled in SUPPORT, and managed with conventional oximeters revealed that for the 9 infants for whom results were available that the percentage of time with ~~and~~ SpO2 > 95% was > 50%.

3. Impact of SUPPORT oximeters algorithm on sat values:

———The oximetry algorithm that was designed for the SUPPORT trial is such that re-conversion of the altered oximeter values does not result in a discrete SpO2 number for every displayed value. SpO2 values, of 93%, 94% 95% and 96% will all be reconverted to a single value in one arm, while 84%, 85%, 86% and 87% will be reconverted to a single value in the other arm. This is a result of having the displayed values return to non-skewed SpO2 values at < 84% and > 96%, a safety design felt to be important by all involved in this trial (See Attached file USCD1). Thus the percentages reported to the DSMC for some of the ranges that include these values were not an accurate representation of the true values. However all values > 96% and < 84% are actual and do not require any conversion.

Percent of time of spent at SpO2 < 84% and > 96%
(RTI, Nov 29, 2005, 14:00 Hrs)

Range	High target (91-95)	Low target (85-89)
< 84%	8.51	16.62
> 96%	22.69	13.60

In the current SUPPORT study, an initial analysis utilizing only unaltered SpO2 values, ~~as shown above , ie~~ those below 84% and above 96%, have shown that one arm had an SpO2 > 96% for 13.6% versus 22.69% of the time for the comparison arm, and the durations of an SpO2 < 84% was also different at 16.62% versus 8.51%. The previously reported value of 36% duration of an SpO2 > 95% for one group represented an artifact of the conversion algorithm as described above. **The values for SpO2s > 96% using ~~unaltered~~ uncorrected data suggests that the SUPPORT trial to date has, if anything, reduced the duration of hyperoxia~~.~~, compared to that experienced by comparable neonates outside the trial.**

In addition, analyses using ~~these values which represent~~ only actual SpO2 values, ~~we can state that the~~demonstrate that infants in this trial are spending approximately 70% of the time with a true SpO2 value between 84% and 96%. We believe that this is information is very encouraging, and suggests that if we are able to further improve adherence to the target ranges that we will achieve an adequate separation between the groups.

4. Impact of inclusion of data from periods in room air on saturation distributions: As part of the SUPPORT trial, we collect information about inhaled oxygen concentration 3 times a day for the first 14 days and daily thereafter. We believe that a more frequent documentation of inhaled oxygen will allow us to determine the actual duration of oxygen exposure. At the present an infant is considered to be receiving supplemental oxygen if he/she requires oxygen for greater than 2 hours. This results in infants being categorized as receiving supplemental oxygen for significant periods when they are actually in room air. This would result in durations of SpO2 greater than 95% that were felt to be modifiable and reported as such when in fact there is no effective treatment for such elevated SpO2s. In addition, we do not know if such SpO2s on room air are associated with any morbidity. From the SUPPORT study data analyses to date we know that infants in room air have SpO2s > 95% for 46% to 69% of the time.

In view of this design, we would suggest that all future analyses for the DSMC evaluate the saturation ranges of <84% and >96% in children on oxygen therapy as those ranges that are outside the target range. ~~considered to be low and high.~~

We believe that the SUPPORT trial will actually define the periods of time that ELBW infants spend with different ranges of SpO2, and that it is essential to collect this information. In addition, as our findings indicate a lower true percent of the time at SpO2 values >95%, and lower median SpO2 values than has previously been reported, we are in fact, reducing the time with high SpO2 values compared to usual care. The SUPPORT trial carefully evaluates risks, and we will be evaluating group differences for all important short and long term outcomes.

The SUPPORT trial methodology actively encourages all caretakers to keep SpO2 < 96% by having alarm limits set at 85% to 95%. These limits were utilized because it was felt that these represented current practice. The oximetry algorithms were designed to keep infants in the narrower target range of 88% to 92% with the realization that setting alarm limits at these values would severely

Formatted
Formatted
Formatted
Formatted
Formatted
Formatted
Formatted

increase the frequency of the alarms sounding. Nevertheless, our results to date suggest that we have decreased the expected percent of time > 95%, and in one group the value of 14% may be as low as is achievable in an actual clinical environment.

We believe that the SUPPORT study will define the durations of high and low SpO2 and will be able to determine if there is a threshold duration of either value that is associated with altered outcomes, and for this reason alone, the SUPPORT trial will be very valuable. All of the procedures outlined below in response to your second concern will also allow us to further increase the percentage of time that the infants are in the maximally altered SpO2 ranges which we believe will further increase separation of these groups.

Response to Issue Number 2

There is concern that we have not achieved adequate separation by the current oximeters and study personnel.

1. As described above, ~~Reviewing~~ the newest analyses ~~available as described above, there are~~ show differences in the durations of low and high SpO2s between the 2 oximeter groups. ~~In addition, A~~a careful analysis of the most recent converted values demonstrates that the cumulative time spent with an SpO2 of 90% or less is 24.3% versus 43%, for the 2 oximeter groups, supporting the ability of the altered oximeters to produce differential SpO2 exposures.

2. We do acknowledge that it would desirable to increase the percentage of time in the narrower target range and towards this end would propose the following changes to SUPPORT:

Formatted

~~A~~1. We will require **documentation that the alarm limits are set and functional as per protocol every 4-6 hours**. We have found that in some units the high alarms are being defeated, and thus believe that such documentation will greatly assist in decreasing the actual time that the SpO2 is > 96%. This task will be assigned to the respiratory therapists, and this procedure is already being done in ~~many~~ some NRN units.

Formatted

~~B~~2. We will immediately initiate a **change in our data collection for FiO2 to ensure that DSMC reports more accurately reflect saturations measured while on oxygen therapy and exclude saturations of infants in room air**. We will change the data form to indicate that the infant was either in oxygen for the entire 24 hours, and if not, will check off the actual hours of oxygen exposure, and we will continue with this from of data collection for the entire time that the infant is receiving oxygen. In the current protocol we collect such information 3 times a day for the first 14 days only and then daily thereafter. We believe that more frequent documentation will allow us to determine the actual time that an infant is in room air. At the present the infant is considered in oxygen if he/she requires oxygen for greater than intermittent use. This results in infants being

Formatted

categorized in oxygen for significant periods when they are in room air. While in room air, we cannot manipulate the SpO2, and thus knowledge of the true time in oxygen will produce a more accurate representation of oximetry results that are subject to care interventions.

~~3~~C.~~.~~ We will initiate **further training and in-service at all the sites to stress the importance of keeping the SpO2 alarm functional and at the limits of 85% and 95%.** In the past these were guidelines, and we will now change the study manual and protocol to indicate these limits are now set by protocol and that violations will be documented. We will encourage all caretakers to aim for an SpO2 value of 90% and make every effort to educate caretakers to make smaller adjustments in FiO2 and ensure that the infant is maintained between the 87% to 93%, the range with the maximal separation of the study oximeters. We will further facilitate the use of the 2 hour and 12 hour histograms showing the infants' actual ranges to provide feedback to the caretakers regarding the percentage of time in the target ranges.

Formatted

D.4. We will **develop guidelines for managing desaturations such that the increase in oxygen is proportional to the severity of the desaturation**. More modulated increases in oxygen during these desaturation events will minimize overshoot and the potential of high SpO2 values.~~We would hope that such changes – ie increasing the FiO2 in steps of 5% as opposed to much larger increases will decrease the resultant overshoots creating the high SpO2 values~~. This will be included in the revised manual of operations.

Formatted

Formatted

5. **We will place bedside cards to indicate the target range.**

Formatted

6. We will **initiate compliance monitoring visits coordinated by RTI** to visit random sites. These visits had been planned, but had not yet been initiated. The teams will consist of a member of RTI and a study coordinator, and they will review the adherence to the protocol and any other relevant issues.

Formatted

We thank the DSMC for their thoughtful concerns. We trust that our plans to move forward with the SUPPORT trial are acceptable to the DSMC. We are anxious to initiate the above changes, seek IRB approvals and re-activate this trial.

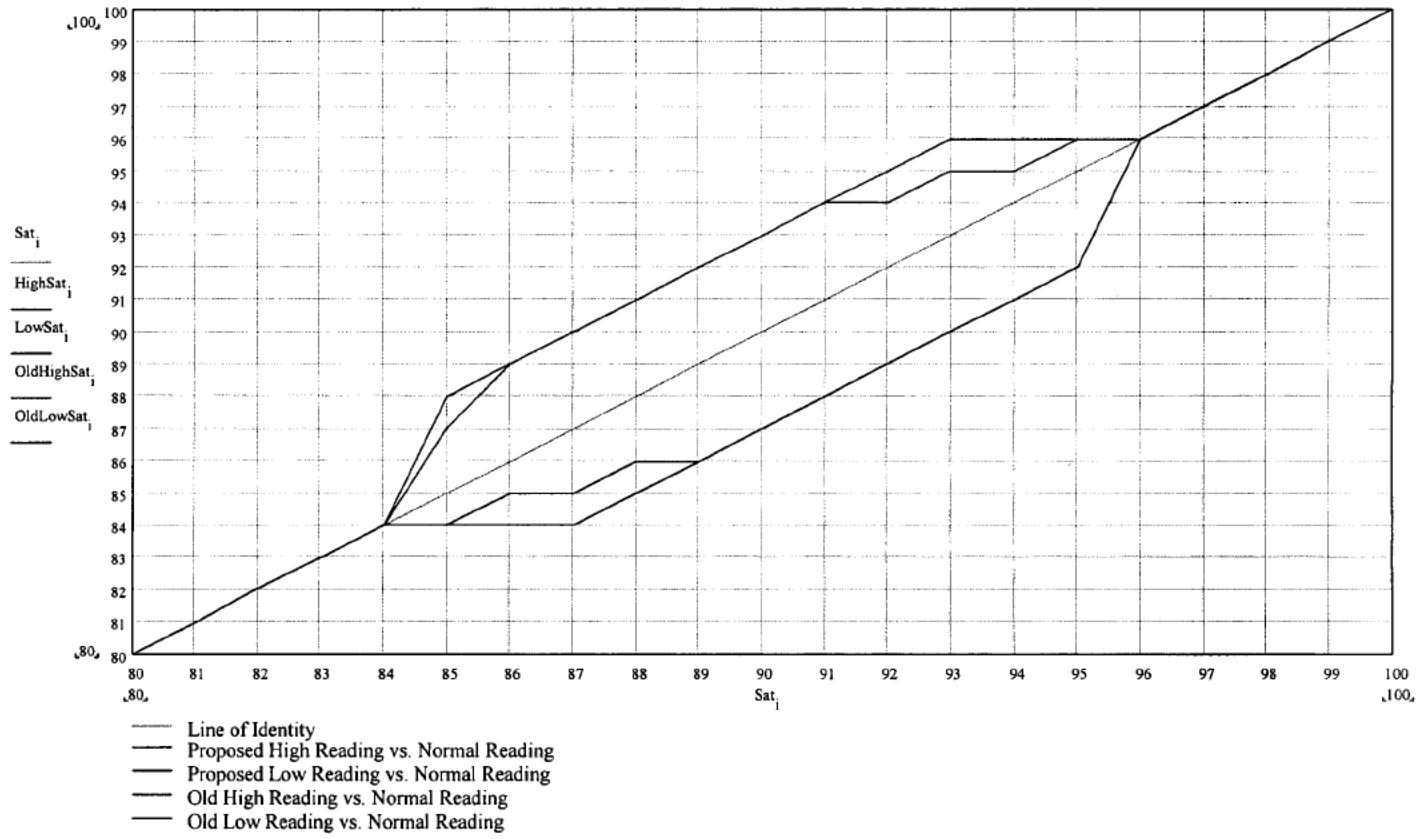
82	82	82
81	81	81
80	80	80
etc	etc	etc



The Low, Actual & High Reading oximeters synchronize for values greater than or equal to 96 % and less than or equal to 84 %.

In the Actual range of 87 % to 95 %, the Low Reading Oximeter displays a value 3 points below actual.

In the Actual range of 85 % to 93 %, the High Reading Oximeter displays a value 3 points above actual.

Converting Low Readings to Normal Readings

Response to DSMC final for Steering Nov 29 05.doc

I think if the dsmb will be satisfied, the Duke irb will be okay w/ moving forward.

I think it's a good response.

Subject: RE: SUPPORT call for the NRN, Wed, Nov 30, 9:30-10:30am ET (6:30-7:30am PT)

Hi
For the morning call, I have attached the response from Neil Finer and the SUPPORT Subcommittee. Please read this over before the call if time permits. Also attached is a late breaker abstract from PAS looking at saturation data in premature infants. If you are unable to make the call, please insure that your alternate PI or another representative for your site is on the call. This is CRUCIAL for input and a DSMC response.

Thanks for all your help.

Rose

LATE BREAKER ABSTRACT SUBMISSION FORM

Abstracts and Payment must be RECEIVED by March 1, 2004

~ Abstracts must be submitted electronically using this form.
~ Abstracts, inclusive of title, authors, institutions, and graphs/tables, must fit in a 6.5 inch x 4 inch space between the two lines (appx. 2,600 characters). Use a font no smaller than 10 pt.
~ You must complete all information and include payment ($50 US) for your abstract to be considered.

Actual vs Intended Pulse Oxygen Saturation (SpO2) in Infants <28 Weeks Gestation

J Hagadorn [1,2], A Furey [1], TH Nghiem [1], S Greene [1], E Abban [1], J Cho [1], P Shrestha [1], A Vora [1], M Landa [2], C Schmid [2], P Hibberd [2], CH Cole [1] and The AVIOx Study Group. [1]Div Newborn Med and [2]Div of Clin Care Research, Tufts-New England Med Ctr, Boston, MA.

Background: Detailed data are not available regarding the actual versus intended SpO2 in infants born <28 weeks gestation (extremely premature newborns, EPNs) in the neonatal period during routine care. **Objective:** To document actual SpO2 in EPNs in the first 4 weeks of life during routine care and compare to the level recommended by local policy/guideline. **Design/Methods:** EPNs <96 hours old were enrolled in a prospective multicenter cohort study. Oximetry data were collected every 2 seconds with masked signal-extraction oximeters for 72 hours in each of the first four weeks of life. Data were compared to SpO2 range prescribed by local institutional policy. **Results:** 14 centers from 3 countries enrolled 78 infants with mean birth weight 863 g (SD 208 g) and mean gestational age 26 wk (SD 1.4 wk). Lower limits of intended ranges at study centers varied between 83-92%, upper limits 92-98%. Infants were monitored for median of 70 hours (25^{th}-75^{th} percentiles 67-71 hr) in each week. Overall median SpO2 for infants on supplemental O2 during the first 4 weeks was 95% (25^{th}-75^{th} percentiles 91-97; range of study center medians 91-96). Centers ranged between 16-71% compliance with intended SpO2 range. Most noncompliance was above intended range. **Conclusions:** Compliance with intended SpO2 range during routine care varied substantially among participating centers, and was generally poor regardless of intended level. These data will assist quality improvement and education efforts, and will aid planning of prospective randomized trials examining level of oxygenation. **Disclosure:** Funded by the SPR Student Research Program; Fight for Sight/Prevent Blindness America; The Tufts-NEMC Research Fund; GCRC/Natl Center for Research Resources MO1-RR00054, and NEI K23 EY/HD00420. Oximeters provided by Masimo Corp.

Briefly describe the reason why the December deadline could not be met:
Study still in progress at December deadline, with only about 60% of enrollment achieved.

Questions? Call, 281-419-0052

In response to the comments and concerns of the DSMC, the SUPPORT committee held a conference call Monday Nov 28th at 10:00 to 1130AM to prepare a response.

- The DSMC made the following 2 comments in their letter regarding the SUPPORT trial. This was generated after they reviewed the oximeter data, which was corrected back to actual SpO2 values from the altered values displayed at the bedside:

1. There is a significant safety and exposure issue for the infants in the high saturation treatment group because an unacceptably high proportion of time was spent by these study subjects in the >95% range

2. There is a futility concern for this arm of the trial in that there does not appear to be substantial separation between the two high and low saturation treatment groups, and the babies are not being kept in the target range the appropriate amount of time in order to meaningfully test the oxygen saturation intervention as originally designed.

Based on these two issues, the consensus of the Committee was to recommend stopping the oxygen saturation arms of the SUPPORT trial due to safety and futility concerns.

We have responded to each of these concerns and our responses are detailed below

Response to Issue Number 1

We appreciate the concern expressed by the DSMC regarding a potential safety issue secondary to durations of SpO2 values > 95%. To date there are no prospective data which define the SpO2s experienced by the ELBW infant from birth as part of usual clinical care. Because no published studies have evaluated the effects of different target SpO2 ranges on important outcomes, this was one of the principle reasons for the design and conduct of the SUPPORT trial. A number of studies have evaluated different alarm limits, but have not reported the actual durations of SpO2 in the various ranges. Nghiem et al in a PAS abstract this year reported that nurses caring for ELBW infants believe that an acceptable oxygen saturation range should include higher upper limits than specified by current policy (Nghiem et al, Nursing Opinions and Practices of Oxygenation in Prematures: The NOPOP Study PAS #3415, 2005). The study by Hagadorn reported as a late breaker at the PAS this year (Hagadorn et al, Actual vs Intended Pulse Oxygen Saturation (SpO2) in Infants <28 Weeks Gestation. PAS 2005, Attached) did report on the experience of monitoring the actual SpO2 for 72 hours in the first 4 weeks of life in 72 ELBW infants. They reported that the "lower limits of intended ranges at study centers varied between 83-92%, upper limits 92-98%. Infants were monitored for a median of 70 hours (25th-75th percentiles 67-71 hr) during each week. Overall median SpO2 for infants on supplemental O2 during the first 4 weeks was 95% (25th-75th percentiles 91-97; range of study center medians 91-96). Centers ranged between 16-71% compliance with their individual intended SpO2 range. Most noncompliance was above intended range." In comparing the data evaluated to date by the DSMC, it is of interest that the mean SpO2 in the 2 Oximeter arms is 90% and 92%, with

medians of 92% and 94%, all of which are below that reported by Hagadorn et al (median=95). The 2 other relevant trials, STOP-ROP and BOOST, both enrolled infants at about 32 weeks PCA, and maintained 2 levels of SpO2, 89% to 94% and 91-94% versus 95% to 98% and 96% to 99%, by administration of oxygen. These studies achieved reasonable separation, but did demonstrate approximately 25% overlap of the intended ranges. It is important to note that these studies were testing two ranges both of which were higher than the lower range of the SUPPORT trial (85% to 89%) and were treating infants who, for the most part, had recovered from their acute disease. In the BOOST trial 70% were < 28 weeks of age at birth (all of SUPPORT is < 28 weeks), 32 weeks postmenstrual age (PMA), and required oxygen at enrollment (Askie et al New England Journal of Medicine. 2003; 349(10):959-967). The STOP-ROP trial enrolled infants with pre-threshold ROP at a PMA of 35.4 + 2.5 weeks of age (Phelps et al Pediatrics. 2000; 105(2):295-310). These trials then gave the higher SpO2 range infants additional oxygen to increase their SpO2 to the desired range. STOP-ROP reported that the infants in the high range had an SpO2 > 95% for > 97% of the monitored time. These studies found an overall increase in pulmonary morbidity in the higher SpO2 range infants.

The oximetry algorithm that was designed for this trial is such that re-conversion of the altered oximeter values does not result in a discrete SpO2 number for every displayed value. SpO2 values, of 93%, 94% 95% and 96% will all be reconverted to a single value in one arm , while 84%, 85%, 86% and 87% will be reconverted to a single value in the other arm. This is a result of having the displayed values return to non-skewed SpO2 values at < 84% and > 96%, a safety design felt to be important by all involved in this trial. Thus the percentages shown that was shown for some of the ranges that include these values were not an accurate representation of the true values. However all values > 96% and < 84% are actual and do not require any conversion.

Percent of time of spent at SpO2 < 84% and > 96%
(RTI, Nov 29, 2005, 14:00 Hrs)

Range	High target (91-95)	Low target (85-89)
< 84%	8.51	16.62
> 96%	22.69	13.60

In the current SUPPORT study, initial analyses utilizing only unaltered SpO2 values as shown above , ie those below 84% and above 96% have shown that one arm had an SpO2 > 96% for 13.6% versus 22.69% of the time for the comparison arm, and the durations of an SpO2 < 84% was also different at 16.62% versus 8.51%. The previously reported value of 36% duration of an SpO2 > 95% represented an artifact of the conversion algorithm as described above. The values for SpO2s > 96% using unaltered data suggests that the SUPPORT trial to date has, if anything, reduced the duration of hyperoxia.

In addition, using these values which represent actual SpO2 values, we can state that the infants in this trial are spending approximately 70% of the time

with a true SpO2 value between 84% and 96%. We believe that this is information is very encouraging, and suggests that if we are able to further improve adherence to the target ranges that we will achieve an adequate separation between the groups.

As part of the SUPPORT trial, we collect information about inhaled oxygen concentration 3 times a day for the first 14 days and daily thereafter. We believe that a more frequent documentation of inhaled oxygen will allow us to determine the actual duration of oxygen exposure. At the present an infant is considered to be receiving supplemental oxygen if he/she requires oxygen for greater than 2 hours. This results in infants being categorized as receiving supplemental oxygen for significant periods when they are actually in room air. This would result in durations of SpO2 greater than 95% that were felt to be modifiable and reported as such when in fact there is no effective treatment for such elevated SpO2s. In addition, we do not know if such SpO2s on room air are associated with any morbidity. From the SUPPORT study data analyses to date we know that infants in room air have SpO2s > 95% for 46% to 69% of the time.

In view of this design, we would suggest that all future analyses evaluate the ranges of <84% and >96% as those ranges that are considered to be low and high.

We believe that the SUPPORT trial will actually define the periods of time that ELBW infants spend with different ranges of SpO2, and that it is essential to collect these data. In addition, as our findings indicate a lower true percent of the time at SpO2 values >95% than has been reported, we are in fact, reducing the time with high SpO2 values compared to usual care. The SUPPORT trial carefully evaluates risks, and we will be evaluating group differences for all important short and long term outcomes.

The SUPPORT trial methodology actively encourages all caretakers to keep SpO2 < 96% by having alarm limits set at 85% to 95%. These limits were utilized because it was felt that these represented current practice. The oximetry algorithms were designed to keep infants in the narrower target range of 88% to 92% with the realization that setting alarm limits at these values would severely increase the frequency of the alarms sounding. Nevertheless, our results to date suggest that we have decreased the expected percent of time > 95%, and in one group this value of 14% may be as low as is achievable in an actual clinical environment.

We believe that the SUPPORT study will define the durations of high and low SpO2 and will be able to determine if there is a threshold duration of either value that is associated with altered outcomes, and for this reason alone, the SUPPORT trial will be very valuable. All of the procedures outlined below in response to your second concern will also allow us to further increase the percentage of time that the infants are in the maximally altered SpO2 ranges which we believe will further increase separation of these groups.

Response to Issue Number 2

There is concern that we have not achieved adequate separation by the current oximeters and study personnel. Reviewing the newest analyses available as described above, there are differences in the durations of low and high SpO2s between the 2 oximeter groups. We do acknowledge that it would desirable to increase the percentage of time in the narrower target range and towards this end would propose the following changes to SUPPORT:

1. We will require documentation that the alarm limits are set and functional as per protocol every 4-6 hours. We have found that in some units the high alarms are being defeated, and thus believe that such documentation will greatly assist in decreasing the actual time that the SpO2 is > 96%. This task will be assigned to the respiratory therapists, and this procedure is already being done in many NRN units.

2. We will collect FiO2 data more frequently, and at a minimum every 4 hours while the infant is requiring oxygen or any form of assisted ventilation. In the current protocol we collect such information 3 times a day for the first 14 days only and then daily thereafter. We believe that more frequent documentation will allow us to determine the actual time that an infant is in room air. At the present the infant is considered in oxygen if he/she requires oxygen for greater than intermittent use. This results in infants being categorized in oxygen for significant periods when they are in room air. While in room air, we cannot manipulate the SpO2, and thus knowledge of the true time in oxygen will produce a more accurate representation of oximetry results that are subject to care interventions.

3. We will initiate further training and in-service at all the sites to stress the importance of keeping the SpO2 alarm functional and at the limits of 85% and 95%. In the past these were guidelines, and we will now change the study manual and protocol to indicate these limits are now set by protocol and that violations will be documented. We will encourage all caretakers to aim for an SpO2 value of 90% and make every effort to make smaller adjustments in FiO2 and ensure that the infant is maintained between the 87% to 93%, the range with the maximal separation of the study oximeters. We will further facilitate the use of the 2 hour and 12 hour histograms showing the infants' actual ranges to provide feedback to the caretakers regarding the percentage of time in the target ranges.

4. We will develop guidelines for managing desaturations such that the increase in oxygen is proportional to the desaturation. We would hope that such changes – ie increasing the FiO2 in steps of 5% as opposed to much larger increases will decrease the resultant overshoots creating the high SpO2 values. This will be included in the revised manual of operations.

5. We will place bedside cards to indicate the target range.

At the present time servo controlled oxygen monitoring is not clinically available, and assigning a separate caretaker to adjust oxygen alone is impractical. In

addition neither of these interventions would represent available care at this time, and the results would not be generalizeable.

We trust that our plans to move forward with the SUPPORT trial are acceptable to the DSMC. We are anxious to initiate the above changes, seek IRB approvals and re-activate this trial.

Subject:

Hello Rose and Everyone

Well I just completed my last call of the day with Marie. She was very helpful, and my thanks to her and Scott for the additional data runs.

These runs proved critical and as we suspected removing the altered values
resulted in a completely different picture for SpO2s > 95%. Ultimately I
have chosen to represent the unaltered values, ie those > 96% and < 84% as
these are always real. If we now calculate the times we find that we are >
96% for about 23% in 1 arm and 14% in the other. On the low side, in parallel, we have SpO2s < 84% for 8% and 16%. Note that we do have Separation!!

Interpreted differently we are between 84% and 96% almost 70% of the time.
I think that this is very good. There is no safety issue as we do not have
excessive times of high SpO2s by anyone's definition. I have rewritten the
document, and included the recent summary data. In addition I will attach
the Hagadorn Abstract as this is not easily found.

Rose, would you please circulate these to the Steering Committee?

Many thanks to you all!!

I am confident that we can move ahead and I feel much better about this trial, and especially the oximeter arm.

Be well and stay tuned

Neil

Hi
For the morning call, I have attached the response from Neil Finer and the SUPPORT Subcommittee. Please read this over before the call if time permits. Also attached is a late breaker abstract from PAS looking at saturation data in premature infants. If you are unable to make the call, please insure that your alternate PI or another representative for your site is on the call. This is CRUCIAL for input and a DSMC response.

Thanks for all your help.

Rose

---

Hello Rose and Everyone

Well I just completed my last call of the day with Marie. She was very helpful, and my thanks to her and Scott for the additional data runs.

These runs proved critical and as we suspected removing the altered values resulted in a completely different picture for SpO2s > 95%. Ultimately I have chosen to represent the unaltered values, ie those > 96% and < 84% as these are always real. If we now calculate the times we find that we are > 96% for about 23% in 1 arm and 14% in the other. On the low side, in parallel, we have SpO2s < 84% for 8% and 16%. Note that we do have Separation!!

Interpreted differently we are between 84% and 96% almost 70% of the time. I think that this is very good. There is no safety issue as we do not have excessive times of high SpO2s by anyone's definition. I have rewritten the document, and included the recent summary data. In addition I will attach the Hagadorn Abstract as this is not easily found.

Rose, would you please circulate these to the Steering Committee?

Many thanks to you all!!

I am confident that we can move ahead and I feel much better about this trial, and especially the oximeter arm.

Be well and stay tuned

Neil

LATE BREAKER ABSTRACT SUBMISSION FORM

Abstracts and Payment must be RECEIVED by March 1, 2004

~ Abstracts must be submitted electronically using this form.
~ Abstracts, inclusive of title, authors, institutions, and graphs/tables, must fit in a 6.5 inch x 4 inch space between the two lines (appx. 2,600 characters). Use a font no smaller than 10 pt.
~ You must complete all information and include payment ($50 US) for your abstract to be considered.

Actual vs Intended Pulse Oxygen Saturation (SpO2) in Infants <28 Weeks Gestation

J Hagadorn [1,2], A Furey [1], TH Nghiem [1], S Greene [1], E Abban [1], J Cho [1], P Shrestha [1], A Vora [1], M Landa [2], C Schmid [2], P Hibberd [2], CH Cole [1] and The AVIOx Study Group. [1]Div Newborn Med and [2]Div of Clin Care Research, Tufts-New England Med Ctr, Boston, MA.

Background: Detailed data are not available regarding the actual versus intended SpO2 in infants born <28 weeks gestation (extremely premature newborns, EPNs) in the neonatal period during routine care. **Objective:** To document actual SpO2 in EPNs in the first 4 weeks of life during routine care and compare to the level recommended by local policy/guideline. **Design/Methods:** EPNs <96 hours old were enrolled in a prospective multicenter cohort study. Oximetry data were collected every 2 seconds with masked signal-extraction oximeters for 72 hours in each of the first four weeks of life. Data were compared to SpO2 range prescribed by local institutional policy. **Results:** 14 centers from 3 countries enrolled 78 infants with mean birth weight 863 g (SD 208 g) and mean gestational age 26 wk (SD 1.4 wk). Lower limits of intended ranges at study centers varied between 83-92%, upper limits 92-98%. Infants were monitored for median of 70 hours (25^{th}-75^{th} percentiles 67-71 hr) in each week. Overall median SpO2 for infants on supplemental O2 during the first 4 weeks was 95% (25^{th}-75^{th} percentiles 91-97; range of study center medians 91-96). Centers ranged between 16-71% compliance with intended SpO2 range. Most noncompliance was above intended range. **Conclusions:** Compliance with intended SpO2 range during routine care varied substantially among participating centers, and was generally poor regardless of intended level. These data will assist quality improvement and education efforts, and will aid planning of prospective randomized trials examining level of oxygenation. **Disclosure:** Funded by the SPR Student Research Program; Fight for Sight/Prevent Blindness America; The Tufts-NEMC Research Fund; GCRC/Natl Center for Research Resources MO1-RR00054, and NEI K23 EY/HD00420. Oximeters provided by Masimo Corp.

Briefly describe the reason why the December deadline could not be met:
Study still in progress at December deadline, with only about 60% of enrollment achieved.

In response to the comments and concerns of the DSMC, the SUPPORT committee held a conference call Monday Nov 28th at 10:00 to 1130AM to prepare a response.

- The DSMC made the following 2 comments in their letter regarding the SUPPORT trial. This was generated after they reviewed the oximeter data, which was corrected back to actual SpO2 values from the altered values displayed at the bedside:

1. There is a significant safety and exposure issue for the infants in the high saturation treatment group because an unacceptably high proportion of time was spent by these study subjects in the >95% range

2. There is a futility concern for this arm of the trial in that there does not appear to be substantial separation between the two high and low saturation treatment groups, and the babies are not being kept in the target range the appropriate amount of time in order to meaningfully test the oxygen saturation intervention as originally designed.

Based on these two issues, the consensus of the Committee was to recommend stopping the oxygen saturation arms of the SUPPORT trial due to safety and futility concerns.

We have responded to each of these concerns and our responses are detailed below

Response to Issue Number 1

We appreciate the concern expressed by the DSMC regarding a potential safety issue secondary to durations of SpO2 values > 95%. To date there are no prospective data which define the SpO2s experienced by the ELBW infant from birth as part of usual clinical care. Because no published studies have evaluated the effects of different target SpO2 ranges on important outcomes, this was one of the principle reasons for the design and conduct of the SUPPORT trial. A number of studies have evaluated different alarm limits, but have not reported the actual durations of SpO2 in the various ranges. Nghiem et al in a PAS abstract this year reported that nurses caring for ELBW infants believe that an acceptable oxygen saturation range should include higher upper limits than specified by current policy (Nghiem et al, Nursing Opinions and Practices of Oxygenation in Prematures: The NOPOP Study PAS #3415, 2005). The study by Hagadorn reported as a late breaker at the PAS this year (Hagadorn et al, Actual vs Intended Pulse Oxygen Saturation (SpO2) in Infants <28 Weeks Gestation. PAS 2005, Attached) did report on the experience of monitoring the actual SpO2 for 72 hours in the first 4 weeks of life in 72 ELBW infants. They reported that the "lower limits of intended ranges at study centers varied between 83-92%, upper limits 92-98%. Infants were monitored for a median of 70 hours (25th-75th percentiles 67-71 hr) during each week. Overall median SpO2 for infants on supplemental O2 during the first 4 weeks was 95% (25th-75th percentiles 91-97; range of study center medians 91-96). Centers ranged between 16-71% compliance with their individual intended SpO2 range. Most noncompliance was above intended range." In comparing the data evaluated to date by the DSMC, it is of interest that the mean SpO2 in the 2 Oximeter arms is 90% and 92%, with

medians of 92% and 94%, all of which are below that reported by Hagadorn et al (median=95). The 2 other relevant trials, STOP-ROP and BOOST, both enrolled infants at about 32 weeks PCA, and maintained 2 levels of SpO2, 89% to 94% and 91-94% versus 95% to 98% and 96% to 99%, by administration of oxygen. These studies achieved reasonable separation, but did demonstrate approximately 25% overlap of the intended ranges. It is important to note that these studies were testing two ranges both of which were higher than the lower range of the SUPPORT trial (85% to 89%) and were treating infants who, for the most part, had recovered from their acute disease. In the BOOST trial 70% were < 28 weeks of age at birth (all of SUPPORT is < 28 weeks), 32 weeks postmenstrual age (PMA), and required oxygen at enrollment (Askie et al New England Journal of Medicine. 2003; 349(10):959-967). The STOP-ROP trial enrolled infants with pre-threshold ROP at a PMA of 35.4 + 2.5 weeks of age (Phelps et al Pediatrics. 2000; 105(2):295-310). These trials then gave the higher SpO2 range infants additional oxygen to increase their SpO2 to the desired range. STOP-ROP reported that the infants in the high range had an SpO2 > 95% for > 97% of the monitored time. These studies found an overall increase in pulmonary morbidity in the higher SpO2 range infants.

The oximetry algorithm that was designed for this trial is such that re-conversion of the altered oximeter values does not result in a discrete SpO2 number for every displayed value. SpO2 values, of 93%, 94% 95% and 96% will all be reconverted to a single value in one arm , while 84%, 85%, 86% and 87% will be reconverted to a single value in the other arm. This is a result of having the displayed values return to non-skewed SpO2 values at < 84% and > 96%, a safety design felt to be important by all involved in this trial. Thus the percentages shown that was shown for some of the ranges that include these values were not an accurate representation of the true values. However all values > 96% and < 84% are actual and do not require any conversion.

Percent of time of spent at SpO2 < 84% and > 96%
(RTI, Nov 29, 2005, 14:00 Hrs)

Range	High target (91-95)	Low target (85-89)
< 84%	8.51	16.62
> 96%	22.69	13.60

In the current SUPPORT study, initial analyses utilizing only unaltered SpO2 values as shown above , ie those below 84% and above 96% have shown that one arm had an SpO2 > 96% for 13.6% versus 22.69% of the time for the comparison arm, and the durations of an SpO2 < 84% was also different at 16.62% versus 8.51%. The previously reported value of 36% duration of an SpO2 > 95% represented an artifact of the conversion algorithm as described above. The values for SpO2s > 96% using unaltered data suggests that the SUPPORT trial to date has, if anything, reduced the duration of hyperoxia.

In addition, using these values which represent actual SpO2 values, we can state that the infants in this trial are spending approximately 70% of the time

with a true SpO2 value between 84% and 96%. We believe that this is information is very encouraging, and suggests that if we are able to further improve adherence to the target ranges that we will achieve an adequate separation between the groups.

As part of the SUPPORT trial, we collect information about inhaled oxygen concentration 3 times a day for the first 14 days and daily thereafter. We believe that a more frequent documentation of inhaled oxygen will allow us to determine the actual duration of oxygen exposure. At the present an infant is considered to be receiving supplemental oxygen if he/she requires oxygen for greater than 2 hours. This results in infants being categorized as receiving supplemental oxygen for significant periods when they are actually in room air. This would result in durations of SpO2 greater than 95% that were felt to be modifiable and reported as such when in fact there is no effective treatment for such elevated SpO2s. In addition, we do not know if such SpO2s on room air are associated with any morbidity. From the SUPPORT study data analyses to date we know that infants in room air have SpO2s > 95% for 46% to 69% of the time.

In view of this design, we would suggest that all future analyses evaluate the ranges of <84% and >96% as those ranges that are considered to be low and high.

We believe that the SUPPORT trial will actually define the periods of time that ELBW infants spend with different ranges of SpO2, and that it is essential to collect these data. In addition, as our findings indicate a lower true percent of the time at SpO2 values >95% than has been reported, we are in fact, reducing the time with high SpO2 values compared to usual care. The SUPPORT trial carefully evaluates risks, and we will be evaluating group differences for all important short and long term outcomes.

The SUPPORT trial methodology actively encourages all caretakers to keep SpO2 < 96% by having alarm limits set at 85% to 95%. These limits were utilized because it was felt that these represented current practice. The oximetry algorithms were designed to keep infants in the narrower target range of 88% to 92% with the realization that setting alarm limits at these values would severely increase the frequency of the alarms sounding. Nevertheless, our results to date suggest that we have decreased the expected percent of time > 95%, and in one group this value of 14% may be as low as is achievable in an actual clinical environment.

We believe that the SUPPORT study will define the durations of high and low SpO2 and will be able to determine if there is a threshold duration of either value that is associated with altered outcomes, and for this reason alone, the SUPPORT trial will be very valuable. All of the procedures outlined below in response to your second concern will also allow us to further increase the percentage of time that the infants are in the maximally altered SpO2 ranges which we believe will further increase separation of these groups.

Response to Issue Number 2

There is concern that we have not achieved adequate separation by the current oximeters and study personnel. Reviewing the newest analyses available as described above, there are differences in the durations of low and high SpO2s between the 2 oximeter groups. We do acknowledge that it would desirable to increase the percentage of time in the narrower target range and towards this end would propose the following changes to SUPPORT:

1. We will require documentation that the alarm limits are set and functional as per protocol every 4-6 hours. We have found that in some units the high alarms are being defeated, and thus believe that such documentation will greatly assist in decreasing the actual time that the SpO2 is > 96%. This task will be assigned to the respiratory therapists, and this procedure is already being done in many NRN units.

2. We will collect FiO2 data more frequently, and at a minimum every 4 hours while the infant is requiring oxygen or any form of assisted ventilation. In the current protocol we collect such information 3 times a day for the first 14 days only and then daily thereafter. We believe that more frequent documentation will allow us to determine the actual time that an infant is in room air. At the present the infant is considered in oxygen if he/she requires oxygen for greater than intermittent use. This results in infants being categorized in oxygen for significant periods when they are in room air. While in room air, we cannot manipulate the SpO2, and thus knowledge of the true time in oxygen will produce a more accurate representation of oximetry results that are subject to care interventions.

3. We will initiate further training and in-service at all the sites to stress the importance of keeping the SpO2 alarm functional and at the limits of 85% and 95%. In the past these were guidelines, and we will now change the study manual and protocol to indicate these limits are now set by protocol and that violations will be documented. We will encourage all caretakers to aim for an SpO2 value of 90% and make every effort to make smaller adjustments in FiO2 and ensure that the infant is maintained between the 87% to 93%, the range with the maximal separation of the study oximeters. We will further facilitate the use of the 2 hour and 12 hour histograms showing the infants' actual ranges to provide feedback to the caretakers regarding the percentage of time in the target ranges.

4. We will develop guidelines for managing desaturations such that the increase in oxygen is proportional to the desaturation. We would hope that such changes – ie increasing the FiO2 in steps of 5% as opposed to much larger increases will decrease the resultant overshoots creating the high SpO2 values. This will be included in the revised manual of operations.

5. We will place bedside cards to indicate the target range.

At the present time servo controlled oxygen monitoring is not clinically available, and assigning a separate caretaker to adjust oxygen alone is impractical. In

addition neither of these interventions would represent available care at this time, and the results would not be generalizeable.

We trust that our plans to move forward with the SUPPORT trial are acceptable to the DSMC. We are anxious to initiate the above changes, seek IRB approvals and re-activate this trial.

<<Response to DSMC Revision Nov 29 05 SD comments.doc>>

In response to the comments and concerns of the DSMC, the SUPPORT committee held a conference call Monday Nov 28th at 10:00 to 1130AM to prepare a response.

- The DSMC made the following 2 comments in their letter regarding the SUPPORT trial. This was generated after they reviewed the oximeter data, which was corrected back to actual SpO2 values from the altered values displayed at the bedside:

1. There is a significant safety and exposure issue for the infants in the high saturation treatment group because an unacceptably high proportion of time was spent by these study subjects in the >95% range

2. There is a futility concern for this arm of the trial in that there does not appear to be substantial separation between the two high and low saturation treatment groups, and the babies are not being kept in the target range the appropriate amount of time in order to meaningfully test the oxygen saturation intervention as originally designed.

Based on these two issues, the consensus of the Committee was to recommend stopping the oxygen saturation arms of the SUPPORT trial due to safety and futility concerns.

We have responded to each of these concerns and our responses are detailed below

Response to Issue Number 1

We appreciate the concern expressed by the DSMC regarding a potential safety issue secondary to durations of SpO2 values > 95%. To date there are no prospective data which define the ~~normal~~ SpO2s experienced by the ELBW infant from birth as part of usual clinical care. Because n~~There have been no~~ published studies have evaluated the effects of~~comparisons of~~ different target SpO2 ranges on~~which have evaluated~~ important outcomes, ~~and~~ this was one of the principle reasons for the design and conduct of the SUPPORT trial. A number of studies~~units~~ have evaluated different~~altered their~~ alarm limits, but have not reported ~~on~~ the actual durations of SpO2 in the various ranges. The study by Hagadorn reported as a late breaker at the PAS last year (-Attached) did report on the experience of monitoring the actual SpO2 for 72 hours in the first 4 weeks of life in 72 ELBW infants. They reported that the "-lower limits of intended ranges at study centers varied between 83-92%, upper limits 92-98%. Infants were monitored for a median of 70 hours (25th-75th percentiles 67-71 hr) during~~in~~ each week. Overall median SpO2 for infants on supplemental O2 during the first 4 weeks was 95% (25th-75th percentiles 91-97; range of study center medians 91-96). Centers ranged between 16-71% compliance with their individual intended SpO2 range. Most noncompliance was above intended range." ~~The median SpO2 in that study was 95%.~~ In comparing the data evaluated to date by the DSMC, it is of interest that the median SpO2 in the 2 Oximeter arms is 90% and 92% well below that reported by Hagadorn et al (median=95%). Data from a single center in the NRN ~~was also reviewed~~ for 9 ELBW infants receiving usual clinical care ~~and that study~~ revealed that these ~~s~~ infants had an SpO2 > 95% for 56% of the time with a range of 38% to 86% (-Walsh, Case Western). The 2

other relevant trials, STOP-ROP and BOOST, both enrolled infants at about 32 weeks PCA, and maintained 2 levels of SpO2, 89% to 94% or 91-94% versus 95% to 98% and 96% to 99%, by administration of oxygen, using oximetry. These studies ~~were able to~~ achieved reasonable separation, but did demonstrate approximately 25% overlap of the intended ranges. It is important to note that these studies were testing ~~the~~ ranges both of which were higher than the lower range of the SUPPORT trial (~~-~~85% to 89%) and were treating infants who, ~~were~~ for the most part, were older, had recovered from ~~over~~ their acute disease, and required oxygen at enrollment . 70% of infants ~~whom~~ in BOOST were < 28 weeks of age at birth (~~-~~all of SUPPORT is < 28 weeks) and ~~who were~~ 32 weeks postmenstrual age (PMA) ~~and required oxygen at enrollment~~. The STOP-ROP trial enrolled infants with pre-threshold ROP at a PMA of 35.4 ± 2.5 weeks of age. These trials then gave the targeted higher SpO2 range infants additional oxygen to increase their SpO2 to the desired range. STOP-ROP reported that the infants in the high range had an SpO2 > 95% for > 97% of the monitored time. These studies found an overall increase in pulmonary morbidity in the higher SpO2 range infants.

In the current SUPPORT study, ~~the~~ initial analyses have shown that one group had an SpO2 > 95% for 14% versus 36% of the time for the comparison arm. Neither of these values is as high as that reported by Hagadorn or found by Walsh, and both are significantly below that found in the BOOST and STOP-ROP trials. Indeed, of interest is the fact that there this degree of separation ~~was such a wide separation~~ in ~~the~~ acutely ill ELBW infants during their initial treatment with oxygen and other ventilatory ~~type of~~ support [I don't understand this last sentence].

As part of the SUPPORT trial, ~~In the current protocol~~ we collect ~~such~~ information about inhaled oxygen concentration ~~administration~~ 3 times a day for the first 14 days only and then daily thereafter. We believe that a closer documentation of inhaled oxygen will allow us to determine the actual duration~~time that an infant is in~~ of room air exposure. At the present, the infant is considered to be in supplemental oxygen if he/she requires oxygen for greater than intermittent use and has supplemental oxygen use documented at least once a day. Therefore ~~This results in~~ infants can be ~~being~~ categorized as in supplemental oxygen for significant periods when they are in room air. This ~~would~~ can result in durations of SpO2 greater than 95% that are interpreted to ~~were felt to~~ be modifiable by clinical care ~~and reported as such~~ when in fact there is no effective treatment for such normally high ~~elevated~~ SpO2s. ~~In addition, we do not know if such SpO2 on room air are associated with any morbidity.~~ From the SUPPORT study data analyses to date we know that infants in room air have SpO2s > 95% for 46% to 69% of the time.

The oximetry algorithm that was designed for this trial is such that re-conversion of ~~the~~ altered oximeter values does not result in ~~an~~ actual SpO2 values for every displayed value. This paradox is explained thus: ~~Thus~~ there are a number of SpO2 values, ie 93%, 94% 95% and 96% which ~~will~~ all result in the same ~~a single~~ value (96%) being represented when converted from displayed to actual values for one range, and for the other range values of 84%, 85%, 86%

and 87% (84%) will also be represented by a single value. This is a result of having the displayed values return to actual SpO2 values < 84% and > 96%, a safety design felt to be important by all involved in this trial. This results in ~~the fact the percentages shown for some of the~~ ranges that include these values to be~~being a~~ less than accurate representation of the true values, since values close to the point where altered values revert to real values have adjusted points superimposed upon true values. A~~However a~~ll values > 96% and < 84% are actual, since the algorithm does not affect these points. In view of this design, we would suggest that all future analyses evaluate the ranges of <84% and ->96%, as those ranges ~~that~~ are irrefutable true measures of ~~considered to be~~ low and high oxygenation.

We do not believe that the time spent > 95%-, 36% for one of the randomized groups,~~,~~ is significantly different from current experience in the care of the ELBW infant. In the SUPPORT Pilot that assessed the design of the oximeter algorithm, we found in 20 infants, all of whom met SUPPORT criteria, that the distribution of SpO2 was greater than 93% for 49% of the time. This was a study of only 12 to 24 hours per child.

We believe that the SUPPORT trial will actually define the periods of time that ELBW infants spend with different ranges of SpO2, and that it is essential to collect these~~is~~ data. In addition, as our findings indicate a lower percent of the time at SpO2 values >95% than has been reported, that we are in fact, reducing the time with high SpO2 values compared to usual care. In addition,- the actual separation that we are seeing suggests that we are achieving in some measure a difference between the groups.

The SUPPORT trial ~~will~~ carefully evaluates ~~the~~ risks, and we will be evaluat~~analyz~~ing group differences for all important short and long term outcomes..

The SUPPORT trial methodology actively encourages all caretakers to keep ~~the infants~~ SpO2 < 96% by having alarm limits set at 85% to 95%. These limit~~numbers~~ were utilized because it was felt that these represented current practice. The oximetry algorithms were designed to keep ~~the~~ infants in the narrower target range of 88% to 92% with the realization that setting alarm limits at these values would severely increase the frequency of the alarms sounding. Nevertheless, our results to date suggest that we have decreased the expected percent of time > 95%, and in one group this value of 14% may be as low as is achievable in an actual clinical environment.

There is also a 10% difference in the time that the infants are below 85%, and this may be an important difference.

We believe that the SUPPORT study will define the durations of high and low SpO2 and will be able to determine if there is a threshold duration of either value that is associated with altered outcomes, and for this reason alone, the SUPPORT trial will be very valuable. All of the procedures outlined below in response to your second concern will also allow us to further increase the percentage of time that the infants are in the maximally altered SpO2 ranges which we believe will further increase separation of these groups.

Response to Issue Number 2

There is concern that we have not achieved adequate separation by the current oximeters and study personnel. As pointed out above, we have achieved differences in the time spent at both high and low SpO2 ranges for the first 153 infants. We are not aware of whether these 2 groups differ by their oxygen exposure, as this has not yet been analyzed. It is however possible that the current differences could result in differences in outcomes, both short and longer term.

It is biologically plausible that higher SpO2 values have a greater impact on oxygen-associated morbidities. That our "usual care" group (SpO2 target 91-95%) spends more than twice as much time in with SpO2 greater than 95% compared to the study group (SpO2 target 85-89%) suggests that we have good "separation" for the purpose of identifying preventable oxygen-associated morbidities.

We do acknowledge that a greater range of separation would be desirable and towards this end would propose the following changes to SUPPORT:

1. We will require documentation that the alarm limits are set and functional as per protocol every 4-6 hours. We have found that in some units the high alarms are being defeated, and thus believe that such documentation will greatly assist in decreasing the actual time that the SpO2 is > 96%. This task will be assigned to the respiratory therapists, and this procedure is already being done on some NRN units.

2. We will collect FiO2 data every hour while the infant is requiring oxygen or any form of assisted ventilation. In the current protocol we collect such information 3 times a day for the first 14 days only and then daily thereafter. We believe that a closer documentation will allow us to determine the actual time that an infant is in room -air. At the present the infant is considered in oxygen if he/she requires oxygen for greater than intermittent use. This results in infants being categorized in oxygen for significant periods when they are in room air. While in room air, we cannot manipulate the SpO2, and thus knowledge of this value will assist us in knowing the true time in oxygen. [we may only need to this for a smaller sample of study subjects and therefore reduce coordinator effort]

3.. We will initiate further in-service at all the sites to stress the importance of keeping the SpO2 alarm functional and at the limits of 85% and 95%. In the past these were guidelines, and we will now change the study manual and protocol to indicate these limits are now set by protocol and that violations will be documented.

4. We will develop guidelines for managing desaturations such that the increase in oxygen is proportional to the desaturation. We would hope that such changes

– ie increasing the FiO2 in steps of 5% as opposed to much larger increases will decrease the resultant overshoots creating the high SpO2 values. This will be included in the revised manual of operations.

5. We will place bedside cards to indicate the target range.

At the present time servo controlled oxygen monitoring is not clinically available, and assigning a separate caretaker to adjust oxygen alone is impractical. In addition neither of these interventions would represent available care at this time, and the results would not be generalizeable.

We trust that our plans to move forward with the SUPPORT trial are acceptable to the DSMC. We are anxious to initiate the above changes, seek IRB approvals and re-activate this trial.

percent ranges.xls

Dear Rose,

It was a pleasure speaking to you. Considering how long oxygen saturation has been monitored over the years it is amazing how much there is to learn even regarding basic practice.

I have included 2 attachments. The first attachment is a copy of the Desaturation abstract in progress. The format is a bit clumsy but it seems to be the best option I could find in which to save the document. The second attachment is an Excel spreadsheet including our 9 NON SUPPORT infants and the time in each target range. The spread sheet includes 2 tables, one in which all days were included and the second in which days in RA were deleted. The tables included data from DOL 1 to 32 wks of age so there are 4-8wks of data for each infant depending on their GA.

If you have any questions or other requests feel free to contact me via email or phone (see below).

Best Regards,

Julie

Title: Progessive Increase in Incidence of Episodic Desaturation in Very Low Birth Weight Infants during the First Month of Life

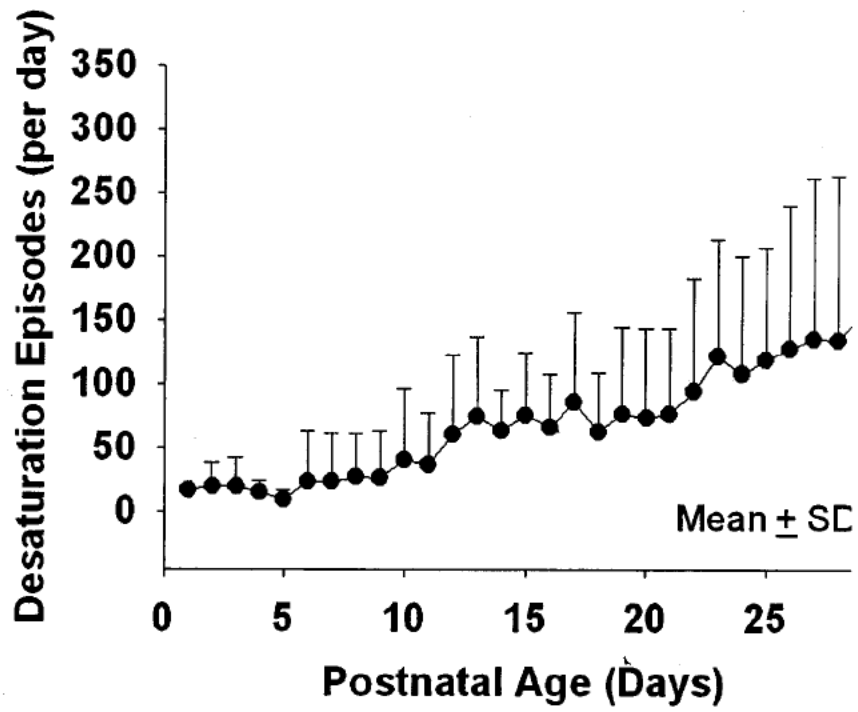
Juliann M Di Fiore, BSEE[1], Arlene Zadell, BSN[1], Michele Walsh, MD[1], Wade Rich, RRT-NPS[2], Neil Finer, MD[2] and Richard J Martin, MD[1]. [1]Pediatrics, Rainbow Babies an States and [2]Pediatrics, University of California, San Diego, California, United States.

Background: Episodes of oxygen desaturation, typically a consequence of apnea or hypoventilation, are almost universal in very low birth weight (VLBW) infants. Hc incidence of such events and whether this changes in early postnatal life.

Objective: To characterize the incidence of episodic desaturation in VLBW infants over the first month of life. We hypothesized that the frequency of these episodes \ respiratory control.

Design/Methods: 9 infants, gestational age 26.1±1.3wks, birthweight 781±159gm, were enrolled in the study. While receiving normal clinical care with no study int sample rate-1 sample per 2 sec, averaging time-2 seconds) during the first 30 days of life. The number of desaturation events (defined as an SaO_2 of <80% for >10s recorded.

Results: The prevalence of episodic desaturation increased with postnatal age ($p<0001$, figure 1) from 16.8±3 to 194±137 episodes at day 1 and day 30, respectivel within a range of 91-96%. 4 infants were intubated for more than 50% of the time period (range 60-100%). The remaining 5 infants were intubated for 1-8 days. Th days (range 1-30days). 8 infants received caffeine during the study period (median 27 days, range 12-30).



Conclusions: In contrast to our hypothesis, the incidence of episodic desaturation increased over the first month of life in this preterm infant population. We specula underlying mechanism and this may overide maturation of respiratory control.

Hi Rose,
How should we proceed with the Breathing Outcomes Study? All the documents were ready to go and I was about to send out the announcement for the telephone interview training dates when the DSMC met last week. Has anyone informed Dr. Stevens about the SUPPORT Trial? Please let me know how you would like to proceed with this. I know that several of the coordinators were working on IRB submissions last week.

Thanks, Jamie

Attachments:	Response to DSMC Revison Nov 28 05.doc 20040226AVIOxLateBreakerDraft.doc

Hi Everyone
Sorry to be somewhat late with this but it took longer than anticipated. I have not included the section on changing the narrow target as below. On rereading we could not be certain that it added anything to the strength of our other arguments.
Please review and make any changes and get these back to me. I know that Rose wants to get this to the Steering Committee.
Thanks
Neil

. We will change the narrow target range from 88% to 92% to 86% and 94% as this represents a range where the skew is still very adequate and is just inside the alarm limits. We discussed altering the alarm limits, but these represented current practice at the time of the study, and if we can increase our time in the target range will result in adequate separation.

In response to the comments and concerns of the DSMC, the SUPPORT committee held a conference call Monday Nov 28th at 10:00 to 1130AM to prepare a response.

- The DSMC made the following 2 comments in their letter regarding the SUPPORT trial. This was generated after they reviewed the oximeter data, which was corrected back to actual SpO2 values from the altered values displayed at the bedside:

1. There is a significant safety and exposure issue for the infants in the high saturation treatment group because an unacceptably high proportion of time was spent by these study subjects in the >95% range

2. There is a futility concern for this arm of the trial in that there does not appear to be substantial separation between the two high and low saturation treatment groups, and the babies are not being kept in the target range the appropriate amount of time in order to meaningfully test the oxygen saturation intervention as originally designed.

Based on these two issues, the consensus of the Committee was to recommend stopping the oxygen saturation arms of the SUPPORT trial due to safety and futility concerns.

We have responded to each of these concerns and our responses are detailed below

Response to Issue Number 1

We appreciate the concern expressed by the DSMC regarding a potential safety issue secondary to durations of SpO2 values > 95%. To date there are no prospective data which define the normal SpO2s experienced by the ELBW infant from birth. There have been no comparisons of different target SpO2 ranges which have evaluated important outcomes, and this was one of the principle reasons for the design and conduct of the SUPPORT trial. A number of units have altered their alarm limits, but have not reported on the actual durations of SpO2 in the various ranges. The study by Hagadorn reported as a late breaker at the PAS last year (Attached) did report on the experience of monitoring the actual SpO2 for 72 hours in the first 4 weeks of life in 72 ELBW infants. They reported that the" lower limits of intended ranges at study centers varied between 83-92%, upper limits 92-98%. Infants were monitored for median of 70 hours (25th-75th percentiles 67-71 hr) in each week. Overall median SpO2 for infants on supplemental O2 during the first 4 weeks was 95% (25th-75th percentiles 91-97; range of study center medians 91-96). Centers ranged between 16-71% compliance with intended SpO2 range. Most noncompliance was above intended range." The median SpO2 in that study was 95%. In comparing the data evaluated to date by the DSMC it is of interest that the median SpO2 in the 2 Oximeter arms is 90% and 92% well below that reported by Hagadorn et al. Data from a single center in the NRN was also reviewed for 9 ELBW infants and that study revealed that theses infants had an SpO2 > 95% for 56% of the time with a range of 38% to 86% (Walsh, Case Western). The 2 other relevant trials, STOP-ROP and BOOST, both enrolled infants at about 32 weeks PCA, and maintained 2 levels of SpO2, 89% to 94% or 91-94% versus 95% to 98% and 96% to 99%,

by administration of oxygen, using oximetry. These studies were able to achieve reasonable separation, but did demonstrate approximately 25% overlap of the intended ranges. It is important to note that these studies were testing the ranges both of which were higher than the lower range of the SUPPORT trial (85% to 89%) and were treating infants who were for the most part over their acute disease, 70% of whom in BOOST were < 28 weeks of age at birth (all of SUPPORT is < 28 weeks) and who were 32 weeks postmenstrual age (PMA) and required oxygen at enrollment. The STOP-ROP trial enrolled infants with pre-threshold ROP at a PMA of 35.4 $\pm$ 2.5 weeks of age. These trials then gave the higher SpO2 range infants additional oxygen to increase their SpO2 to the desired range. STOP-ROP reported that the infants in the high range had an SpO2 > 95% for > 97% of the monitored time. These studies found an overall increase in pulmonary morbidity in the higher SpO2 range infants.

In the current SUPPORT study, the initial analyses have shown that one group had an SpO2 > 95% for 14% versus 36% of the time. Neither of these values is as high as that reported by Hagadorn or found by Walsh, and both are significantly below that found in the BOOST and STOP-ROP trials. Indeed, of interest is the fact that there was such a wide separation in the acutely ill ELBW infants during their treatment with oxygen and other ventilator type of support.

In the current protocol we collect such information about oxygen administration 3 times a day for the first 14 days only and then daily thereafter. We believe that a closer documentation will allow us to determine the actual time that an infant is in room air. At the present the infant is considered in oxygen if he/she requires oxygen for greater than intermittent use. This results in infants being categorized in oxygen for significant periods when they are in room air. This would result in durations of SpO2 greater than 95% that were felt to be modifiable and reported as such when in fact there is no effective treatment for such elevated SpO2s. In addition we do not know if such SpO2 on room air are associated with any morbidity. From the SUPPORT study data analyses to date we know that infants in room air have SpO2s > 95% for 46% to 69% of the time.

The algorithm that was designed for this trial is such that re-conversion of the altered oximeter values does not result in an actual SpO2 value for every displayed value. Thus there are a number of SpO2 values, ie 93%, 94% 95% and 96% which will all result in a single value being represented when converted from displayed to actual values for one range, and for the other range values of 84%, 85%, 86% and 87% will also be represented by a single value. This is a result of having the displayed values return to actual SpO2 values < 84% and > 96%, a safety design felt to be important by all involved in this trial. This results in the fact the percentages shown for some of the ranges that include these values being a less than accurate representation of the true values. However all values > 96% and < 84% are actual. In view of this design, we would suggest that all future analyses evaluate the ranges of <84% and >96% as those ranges that are considered to be low and high.

We do not believe that the time spent > 95% , 36% for one of the randomized groups,, is significantly different from current experience in the care of the ELBW infant. In the SUPPORT Pilot that assessed the design of the

oximeter algorithm, we found in 20 infants all of whom met SUPPORT criteria, that the distribution of SpO2 was greater than 93% for 49% of the time. This was a study of only12 to 24 hours per child.

We believe that the SUPPORT trial will actually define the periods of time that ELBW infants spend with different ranges of SpO2, and that it is essential to collect this data. In addition, as our findings indicate a lower percent of the time at SpO2 values >95% than has been reported, that we are in fact, reducing the time with high SpO2 values. In addition, the actual separation that we are seeing suggests that we are achieving in some measure a difference between the groups.

The SUPPORT trial will carefully evaluate the risks, and we will be analyzing group differences for all important short and long term outcomes..

The SUPPORT trial methodology actively encourages all caretakers to keep the infants SpO2 < 96% by having alarm limits set at 85% to 95%. These numbers were utilized because it was felt that these represented current practice. The algorithms were designed to keep the infants in the narrower target range of 88% to 92% with the realization that setting alarm limits at these values would severely increase the frequency of the alarms sounding. Nevertheless, our results to date suggest that we have decreased the expected percent of time > 95%, and in one group this value of 14% may be as low as is achievable in an actual clinical environment.

There is also a 10% difference in the time that the infants are below 85%, and this may be an important difference.

We believe that the SUPPORT study will define the durations of high and low SpO2 and will be able to determine if there is a threshold duration of either value that is associated with altered outcomes, and for this reason alone, the SUPPORT trial will be very valuable. All of the procedures outlined below in response to your second concern will also allow us to further increase the percentage of time that the infants are in the maximally altered SpO2 ranges which we believe will further increase separation of these groups.

Response to Issue Number 2

There is concern that we have not achieved adequate separation by the current oximeters and study personnel. As pointed out above we have achieved differences in the time spent at both high and low SpO2 ranges for the first 153 infants. We are not aware of whether these 2 groups differ by their oxygen exposure, as this has not yet been analyzed. It is however possible that the current differences could result in differences in outcomes, both short and longer term. We do acknowledge that a greater range of separation would be desirable and towards this end would propose the following changes to SUPPORT:

1. We will require documentation that the alarm limits are set and functional as per protocol every 4-6 hours. We have found that in some units the high alarms are being defeated, and thus believe that such documentation will greatly assist in decreasing the actual time that the SpO2 is > 96%. This task will be assigned

to the respiratory therapists, and this procedure is already being done on some NRN units.

2. We will collect FiO2 data every hour while the infant is requiring oxygen or any form of assisted ventilation. In the current protocol we collect such information 3 times a day for the first 14 days only and then daily thereafter. We believe that a closer documentation will allow us to determine the actual time that an infant is in room air. At the present the infant is considered in oxygen if he/she requires oxygen for greater than intermittent use. This results in infants being categorized in oxygen for significant periods when they are in room air. While in room air, we cannot manipulate the SpO2, and thus knowledge of this value will assist us in knowing the true time in oxygen.

3.. We will initiate further in-service at all the sites to stress the importance of keeping the SpO2 alarm functional and at the limits of 85% and 95%. In the past these were guidelines, and we will now change the study manual and protocol to indicate these limits are now set by protocol and that violations will be documented.

4. We will develop guidelines for managing desaturations such that the increase in oxygen is proportional to the desaturation. We would hope that such changes – ie increasing the FiO2 in steps of 5% as opposed to much larger increases will decrease the resultant overshoots creating the high SpO2 values. This will be included in the revised manual of operations.

5. We will place bedside cards to indicate the target range.

At the present time servo controlled oxygen monitoring is not clinically available, and assigning a separate caretaker to adjust oxygen alone is impractical. In addition neither of these interventions would represent available care at this time, and the results would not be generalizeable.

We trust that our plans to move forward with the SUPPORT trial are acceptable to the DSMC. We are anxious to initiate the above changes, seek IRB approvals and re-activate this trial.

LATE BREAKER ABSTRACT SUBMISSION FORM

Abstracts and Payment must be RECEIVED by March 1, 2004

~ Abstracts must be submitted electronically using this form.
~ Abstracts, inclusive of title, authors, institutions, and graphs/tables, must fit in a 6.5 inch x 4 inch space between the two lines (appx. 2,600 characters). Use a font no smaller than 10 pt.
~ You must complete all information and include payment ($50 US) for your abstract to be considered.

Actual vs Intended Pulse Oxygen Saturation (SpO2) in Infants <28 Weeks Gestation

J Hagadorn [1,2], A Furey [1], TH Nghiem [1], S Greene [1], E Abban [1], J Cho [1], P Shrestha [1], A Vora [1], M Landa [2], C Schmid [2], P Hibberd [2], CH Cole [1] and The AVIOx Study Group. [1]Div Newborn Med and [2]Div of Clin Care Research, Tufts-New England Med Ctr, Boston, MA.

Background: Detailed data are not available regarding the actual versus intended SpO2 in infants born <28 weeks gestation (extremely premature newborns, EPNs) in the neonatal period during routine care. **Objective:** To document actual SpO2 in EPNs in the first 4 weeks of life during routine care and compare to the level recommended by local policy/guideline. **Design/Methods:** EPNs <96 hours old were enrolled in a prospective multicenter cohort study. Oximetry data were collected every 2 seconds with masked signal-extraction oximeters for 72 hours in each of the first four weeks of life. Data were compared to SpO2 range prescribed by local institutional policy. **Results:** 14 centers from 3 countries enrolled 78 infants with mean birth weight 863 g (SD 208 g) and mean gestational age 26 wk (SD 1.4 wk). Lower limits of intended ranges at study centers varied between 83-92%, upper limits 92-98%. Infants were monitored for median of 70 hours (25^{th}-75^{th} percentiles 67-71 hr) in each week. Overall median SpO2 for infants on supplemental O2 during the first 4 weeks was 95% (25^{th}-75^{th} percentiles 91-97; range of study center medians 91-96). Centers ranged between 16-71% compliance with intended SpO2 range. Most noncompliance was above intended range. **Conclusions:** Compliance with intended SpO2 range during routine care varied substantially among participating centers, and was generally poor regardless of intended level. These data will assist quality improvement and education efforts, and will aid planning of prospective randomized trials examining level of oxygenation. **Disclosure:** Funded by the SPR Student Research Program; Fight for Sight/Prevent Blindness America; The Tufts-NEMC Research Fund; GCRC/Natl Center for Research Resources MO1-RR00054, and NEI K23 EY/HD00420. Oximeters provided by Masimo Corp.

Briefly describe the reason why the December deadline could not be met:
Study still in progress at December deadline, with only about 60% of enrollment achieved.

---

Hello Everyone

In preparing for tomorrows call I thought we should have our strategy in front of us so that we alter it as needed.

Thanks for your suggestions

I have added the relevant attachments; these include the DSMC report, the data that the DSMC reviewed, the data for room air only, and Michele's data from Case.

In addition Michele sent data for 9 Non-SUPPORT infants with the SpO2 distribution:

To summarize the distribution:

> 95% sat - 56% (range 38-86)

90-95% sat - 26% (range 8-33%)

85-89% sat - 8% (range 2-13%)

< 85% sat - 11% (range 3-25%)

We also have the data from the Pilot that was done to test the algorithm separation performed at Sharp Mary Birch by Maynard.

20 recordings of ~24 hr each or ~500 hours of recording
Entry criteria identical to Support Trial
All infants on IMV or CPAP and Supplemental Oxygen
Sat alarms 84 and 96% with written orders and posted signs to keep SaO2 88-92%

Results from normal (non-skewed) Masimo oximeters:

<84%:	10% of time
84-87%:	10% of time
88-92%:	29% of time
93-96%:	40% of time
>96%:	9% of time

This is not directly comparable but shows considerable time with high SpO2. These ranges are not identical but consistent with Michele's data and the findings from the initial 153 SUPPORT infants

To review - The DSMC made the following 2 comments:

- There is a significant safety and exposure issue for the infants in the high saturation treatment group because an unacceptably high proportion of time was spent by these study subjects in the >95% range
- There is a futility concern for this arm of the trial in that there does not appear to be substantial separation between the two high and low saturation treatment groups, and the babies are not being kept in the target range the appropriate amount of time in order to meaningfully test the oxygen saturation intervention as originally designed.

Based on these two issues, the consensus of the Committee was to recommend stopping the oxygen saturation arms of the SUPPORT trial due to safety and futility concerns.

Other relevant data – in BOOST the infants in the higher SpO2 range had SpO2s> 95% for 90% of the time. These were infants who were unable to maintain SpO2 > 94% in room air

In reviewing the DSMC comments I believe that our strategy moving forward should be as follows:

1. We should strenuously argue that the percent of time over 95% in NOT a safety issue as there is no antecedent data that such SpO2s for such a duration, ie 35% > 95% are toxic. We would argue that this duration is actually lower than may be expected.
2. We would additionally hope that an analysis will show excessive time at 96% which actually may represent values from 93% to 96%. This will also be true for the value of 84% which may be over-represented. This is a phenomenon of back converting the algorithm when trying to determine true SpO2 values from the altered oximeters. I have attached the actual skew as an attachment.
3. I would suggest that we change the low alarm to 80% and the high to 94%. This should push us toward the narrow targets
4. We need to develop increased in-service at all sites to encourage keeping infants in the narrower ranges of 88% to 92% - Signs at bedside, rewards by histogram results, and monthly recognition of the units with the best target data. Please suggest any mechanisms that you think would be effective
5. We need to rewrite the manual and protocol to clarify that we are aiming to produce different oxygen exposures using different SpO2 limits
6. I would suggest that we collect more FiO2 data. I would assume that all units keep hourly FiO2 data for all infants on ventilators and CPAP. I would propose that we collect hourly data for at least the first 14 days for all such infants and try to continue to collect such data for all infants who require oxygen via any mechanism. For prongs we would collect flow and and FiO2, and daily weight. We do have technology to continuously record FiO2. I will briefly discuss this – we could do this for the next 10-20 infants or more and compare with the SpO2 data. Please think about this.
7. I would fight vigorously to continue the trial as is, and re-evaluate the oximetry data after a further 100-200 infants
8. If we are forced to consider dropping the oximetry arm, then I would propose that we have all the Masimo oximeters converted to normal and continue to use them to collect the data about the actual SpO2 exposures of this population which will still be unique and incredibly useful in looking at durations of hyperoxia and hypoxia in the ELBW and their outcomes.
9. Other possibilities – redesign of the algorithm going below 85%, using a 3-5% SpO2 offset without correction for 1 arm, and standard oximeters for the other. I believe that Masimo was reluctant to design such an offset on the belief that clinicians would want to know the true SpO2 of an infant if below 85%.

Thanks for staying tuned. Talk to you in the morning.
Be well
Neil

MEMORANDUM

T0: Institutional Review Boards of the Neonatal Research Network (NRN) Sites

FROM: Gordon Avery, MD
Chair of the Data Safety and Monitoring Committee (DSMC) of the NRN (as prepared by the Data Coordinating Center)

SUBJECT: Summary of the November 22, 2005 Data Safety and Monitoring Committee Conference Call

The DSMC for the Neonatal Research Network had a teleconference meeting at 11:00AM on November 22, 2005 to review data on oxygen saturations ranges from the SUPPORT Trial. Attached is a summary of the DSMC deliberations for this study.

NEONATAL RESEARCH NETWORK

DATA SAFETY AND MONITORING COMMITTEE

DRAFT MINUTES

November 22, 1005

The Data Safety and Monitoring Committee for the Neonatal Research Network met via teleconference at 11:00AM on November 22, 2005 to discuss and review data from the oxygen saturation arm of the SUPPORT Trial. The DSMC members in attendance were Drs. Avery (chair), Boyle, Gleason, Redmond, Willinger, Hunt and Allen. Drs. Das and Gantz and Ms. Hastings and Ms. Zarterka-Baxter from the Data Center were also present.

Tables representing the percent of time spent in each O2 range (days on supplemental O2 only) for each of the low and high treatment groups were previously e-mailed to the Committee prior to the call. These tables were based on study data as of November 7, 2005 (153 study subjects).

After reviewing and discussing these data, the DSMC expressed significant concern about the following two issues:

- There is a significant safety and exposure issue for the infants in the high saturation treatment group because an unacceptably high proportion of time was spent by these study subjects in the >95% range
- There is a futility concern for this arm of the trial in that there does not appear to be substantial separation between the two high and low saturation treatment groups, and the babies are not being kept in the target range the appropriate amount of time in order to meaningfully test the oxygen saturation intervention as originally designed.

Based on these two issues, the consensus of the Committee was to recommend stopping the oxygen saturation arms of the SUPPORT trial due to safety and futility concerns.

NOTE: Dr Dwyane Alexander, Director of NICHD, reviewed the above recommendation and discussed the specifics with Dr. Rose Higgins, Program Scientist for the Neonatal Research Network, and after thorough consideration of all of the issues, agreed with the recommendation and requested that enrollment be temporarily suspended into the trial until one can assure that the oxygen saturations are in the planned target range. Sites were notified on November 22, 2005 that enrollment should be temporarily suspended until further notice.

---

Hello Everyone
In preparing for tomorrows call I thought we should have our strategy in front of us so that we alter it as needed.
Thanks for your suggestions
I have added the relevant attachments; these include the DSMC report, the data that the DSMC reviewed, the data for room air only, and Michele's data from Case.
In addition Michele sent data for 9 Non-SUPPORT infants with the SpO2 distribution:
To summarize the distribution:
> 95% sat - 56% (range 38-86)
90-95% sat - 26% (range 8-33%)
85-89% sat - 8% (range 2-13%)
< 85% sat - 11% (range 3-25%)
We also have the data from the Pilot that was done to test the algorithm separation performed at Sharp Mary Birch by Maynard.

20 recordings of ~24 hr each or ~500 hours of recording
Entry criteria identical to Support Trial
All infants on IMV or CPAP and Supplemental Oxygen
Sat alarms 84 and 96% with written orders and posted signs to keep SaO2 88-92%

Results from normal (non-skewed) Masimo oximeters:

<84%:	10% of time
84-87%:	10% of time
88-92%:	29% of time
93-96%:	40% of time
>96%:	9% of time

This is not directly comparable but shows considerable time with high SpO2. These ranges are not identical but consistent with Michele's data and the findings from the initial 153 SUPPORT infants

To review - The DSMC made the following 2 comments:

- There is a significant safety and exposure issue for the infants in the high saturation treatment group because an unacceptably high proportion of time was spent by these study subjects in the >95% range
- There is a futility concern for this arm of the trial in that there does not appear to be substantial separation between the two high and low saturation treatment groups, and the babies are not being kept in the target range the appropriate amount of time in order to meaningfully test the oxygen saturation intervention as originally designed.

Based on these two issues, the consensus of the Committee was to recommend stopping the oxygen saturation arms of the SUPPORT trial due to safety and futility concerns.

Other relevant data – in BOOST the infants in the higher SpO2 range had SpO2s> 95% for 90% of the

time. These were infants who were unable to maintain SpO2 > 94% in room air

In reviewing the DSMC comments I believe that our strategy moving forward should be as follows:

1. We should strenuously argue that the percent of time over 95% in NOT a safety issue as there is no antecedent data that such SpO2s for such a duration, ie 35% > 95% are toxic. We would argue that this duration is actually lower than may be expected.
2. We would additionally hope that an analysis will show excessive time at 96% which actually may represent values from 93% to 96%. This will also be true for the value of 84% which may be over-represented. This is a phenomenon of back converting the algorithm when trying to determine true SpO2 values from the altered oximeters. I have attached the actual skew as an attachment.
3. I would suggest that we change the low alarm to 80% and the high to 94%. This should push us toward the narrow targets
4. We need to develop increased in-service at all sites to encourage keeping infants in the narrower ranges of 88% to 92% - Signs at bedside, rewards by histogram results, and monthly recognition of the units with the best target data. Please suggest any mechanisms that you think would be effective
5. We need to rewrite the manual and protocol to clarify that we are aiming to produce different oxygen exposures using different SpO2 limits
6. I would suggest that we collect more FiO2 data. I would assume that all units keep hourly FiO2 data for all infants on ventilators and CPAP. I would propose that we collect hourly data for at least the first 14 days for all such infants and try to continue to collect such data for all infants who require oxygen via any mechanism. For prongs we would collect flow and and FiO2, and daily weight. We do have technology to continuously record FiO2. I will briefly discuss this – we could do this for the next 10-20 infants or more and compare with the SpO2 data. Please think about this.
7. I would fight vigorously to continue the trial as is, and re-evaluate the oximetry data after a further 100-200 infants
8. If we are forced to consider dropping the oximetry arm, then I would propose that we have all the Masimo oximeters converted to normal and continue to use them to collect the data about the actual SpO2 exposures of this population which will still be unique and incredibly useful in looking at durations of hyperoxia and hypoxia in the ELBW and their outcomes.
9. Other possibilities – redesign of the algorithm going below 85%, using a 3-5% SpO2 offset without correction for 1 arm, and standard oximeters for the other. I believe that Masimo was reluctant to design such an offset on the belief that clinicians would want to know the true SpO2 of an infant if below 85%.

Thanks for staying tuned. Talk to you in the morning.
Be well
Neil

Subject: SUPPORT and US POST

Dear Neil and Rosemary (and Tonse),
First, I hope this finds each of you well.
The BIDMC CCI (i.e. IRB) reviewed the pilot randomized trial for US POST.
BIDMC CCI would like to contact either one or both of you regarding status of NICHD-Neo Research Network's SUPPORT and the saturation targets.
The issue relates to how IRBs of NICHD network centers viewed the risk to the participants.

BIDMC CCI asked if I viewed this study as greater than minimal risk to participants.
My response: 'Not above minimal risk.' Rationale: Since the overall range of both targets (SpO2 85-95%) was within the current range used by many NICUs, I did not view that this study was increasing the risk of an eligible patient beyond their usual care. There is insufficient evidence to claim any SpO2 targeted range as 'standard of care'. However, if there is a net benefit of one targeted zone compared to another, or a tradeoff in outcomes, then one of these targeted zones may increase the risk of certain patients for certain outcomes. So, I am requesting your permission to provide your contact information for a member of the BIDMC CCI to contact you.

I would also like to touch base with you. Realizing we are upon the holidays, I would like to speak with you before Wednesday mid-day if possible.
If not, let me know times that would be good to call you.

Thank you. I wish you a very Happy Thanksgiving. -
Cindy

Neil:

We are working on getting this done. However, I dont think we will have it in time for our call on Monday. As I understand it, the data dump from the pulse oximeters is so immense that a huge amount of data processing and compression has to be done at our end first before the data is an analyzable form. Currently we are in the process of re-programming that pre-processing component so that we can look at the data at the finer level that we need. Once our programmers get that done (they already started working on it on Wednesday, but RTI is closed Thurs/Friday for Thanksgiving), Marie will get you these numbers as soon as we can.

Thanks

Abhik

Maybe data of % of time in each sat %from 85 to 100 would be most helpful rather than data analyzed by ranges of sats.

What do you all think? Wally

Subject: RE: re sat distribution data

I forgot to add a bit of background here. In August, with prodding from Neil and Wally we approached the DSMC with the subcommittee's request to periodically monitor the sat data by treatment group to ensure that sufficient separation was being achieved (see table below). The DSMC decided that any such monitoring should be done by it, and not the study investigators. It was in this spirit that this data was then shown to the DSMC. We sent them the data in September, but it took a while to find a time for all of them to meet. However, the pattern we saw in September was virtually identical to what we see now (in the tables you have).

Thanks

Abhik

Data	High Saturation	Low Saturation
% of time in range 85-89%		
% of time in range 90%		
% of time in range 91-95		
% of time below range (= 84%)		
% of time above range (= 96%)		
Average Saturation		
Minimum Saturation		
Maximum Saturation

I think Ken's original intent in sending this to the DSMC was primarily a futility concern about inadequate separation -- kids in the low sat arm were in fact in the high target group more often (45% time) than kids in the high sat arm (39%). That could not be shown in a masked

way. In any case, in my experience DSMC's rarely buy this masking business -- if we mask they just come back and ask us to unmask them.

Subject: RE: re sat distribution data

Hello All

I agree with Ed's comments. In fact we wanted to create different oxygen exposures and the way to do this was to have different periods of time at different SpO2 levels, and it would appear that we have succeeded.

I am also uncertain why non blinded data was evaluated. Our previous comments were that some units were experiencing that the high alarms were not being set. We did not postulate that this was an issue for one or other arm of the trial, but rather a response to frequent alarms. It is the alarms that work to keep the babies in range.

Also we need to understand that the design of the algorithms was also to push the infants into the middle range. I will try to explain this. For an infant whose oximeter displays 88% to 92% when the actual SpO2 is 91% to 95%, as the true, SpO2 increases toward 95%, the display will increase to 95% to 96% and the alarm can be activated (with the appropriate time delay etc) at actual values of 94-95%. Thus this infant will alarm when the actual SpO2 is BELOW the upper limit of 95%. This will tend to keep the infant more within the desired target range. The same will happen for infants in the lower range, in that when their actual SpO2 is 87%, the display will show 85% and any further decrease will trigger the alarm.

In reviewing the DSMC comments I believe that our strategy moving forward should be as follows:

1. We should strenuously argue that the percent of time over 95% in NOT a safety issue as there is no antecedent data that such SpO2s for such a duration, ie 35% > 95% are toxic. We would argue that this duration is actually lower than may be expected.
2. We would additionally hope that an analysis will show excessive time at 96% which actually may represent values from 93% to 96%
3. I would suggest that we change the low alarm to 80% and the high to 94%. This should push us toward the narrow targets
4. We need to rewrite the manual and protocol to clarify that we are aiming to produce different oxygen exposures using different SpO2 limits
5. I would fight vigorously to continue the trial as is, and re-evaluate the oximetry data after a further 100-200 infants
6. If we are forced to consider dropping the oximetry arm, then have all the Masimo oximeters converted to normal and continue to use them to collect the data about the actual SpO2 exposures of this population which will still be unique and incredibly useful in looking at durations of hyperoxia and hypoxia in the ELBW and their outcomes.

Please consider these suggestions and let me know your thoughts and suggestions

I would like to be prepared for our Monday call.

Have a great Thanksgiving

Do we have any details on this issue?
What I understand is that there is a concern about exposure to high O2 sat disproportionately in one arm? If it's the "high" arm, then this is the purpose of the study, i.e. to see if decreasing oxygen exposure reduces BPD and ROP. Am I missing the boat? When are we going to see the actual concerns of the DSMC?

>>> "Neil Finer" <nfiner@ucsd.edu> 11/22/2005 6:30:43 PM >>>

Hi Michele and all
I have reviewed Abbot's abstract and he found that the SpO2 was > 95% for

about 17% of the time.
In addition the skew for correcting the stored values in the oximeter back to real unaltered values is such that for the group in high range ie 88% to 92% is actually 91% to 95%, in the process of correcting, there are a number
of real, actual SpO2 values - 93%, 94%, 95% and 96% which are all converted
to a display value of 96% because of rounding of decimal points (The Masimo
cannot display decimals and we had agreed to this formula as 96% cannot be
linked to 4 different actual SpO2 values).
We were aware of this, and used this because we wished to maintain the separation over the widest range. This will represent a problem in reviewing
the unskewed data in that there will be an over-representation of values at 96% for the high range infants and 85% for the low range infants.
RTI in converting the data back to "normal" will only see a 96% value for any value of 93%, 94% or 95% or 96% in the 91-95% target infants, and thus
we will find a much increased percentage for the actual value of 96% after data conversion, as was done.
We therefore need to look at the value of 96% separately, as we do for 85%
We need to understand that values of 96% after conversion will represent actual values of anywhere from 93 to 96%.
However we had agreed that this would not be realistic so that fractions were assigned most of which if corrected to a full integer would read 96%.

This now raises the issue of the study intent and design. We did not design
the trial to produce different SpO2s but rather to use the SpO2 to create different oxygen exposures. To my knowledge we did not analyze the FiO2 for
the 2 groups. In addition we do not know at present if the % of time > 95%
and < 85% are different than what is normally experienced for ELBW infants.
We need to know the percentage of time at the single value of 96% and probably similarly at 85%. Some values of 96% will actually represent values
that should be within the 92% to 95% range, but we will have no ability to know this.
I believe that if we achieve close to 60% within 85% to 95% with the current
skews, that we will achieve FiO2 differences.
STOP ROP kept the high range infants at > 95% for > 90% of the time. I am
uncertain as to the known risk of any value for SpO2 > 95% below 90%.
I also believe that we may increase our time in the narrow and broader ranges by lowering the low alarm to 80% and the high alarm to 94%.
Lets think all of this over.
Rose, can you ask Marie Ganz to provide us the actual percentage of time in
the various ranges for all of the infants (non corrected data) for the time only in room air. She previously gave us in oxygen and overall. The room air
only will provide a ranges of SpO2 > 95% and we can look at this in interpreting the percent time > 96%.

I believe that we can probably move ahead with the trial and I am prepared
to argue for this.
In spite of this, have a peaceful and restful Thanksgiving
Neil

Hi Wally

The Poets study demonstrated compliance for a range of SpO2 from 87% to 96%.
We don't know our percentage of time in this range. We will have more knowledge when we see the individual SpO2 data and even then because the values of 85% and 96% will be overrepresented, I am not sure that we will
get all the answers.

I think that a 5% range is probably too small to hit with regularity in the
majority of NICUs without a dedicated person doing nothing else. We could
widen this maximal separation if we change the skew to go below 85%. We were
reluctant to go there before. There is really no new data to indicate that
going lower is safer. In fact, there is essentially no data as large as the
study database for true SpO2 values of 84% and less and 96% and greater.
This study will provide the data as to whether any duration below or above
these values is beneficial or harmful. I would like to push for lowering the
alarm limits.

Another paradoxical thought as suggested by Maynard is that we decrease the
averaging and alarm delays, so that the care teams are more quickly informed
when infants go out of the narrow target range.

I am also not sure that we haven't created to different oxygen exposures.

The two randomized groups of infants differ by 10% for the percent of time
below 85%. This could be associated with a difference in oxygen exposure. In
addition this difference could drive different outcomes which is exactly what we want to test.

However we only collect these values 3 times per day. We do have technology
to collect the FiO2 continuously and we use this for some of our DR research. Should we try to do this for 10-20 infants in each range?

I will keep thinking on this till we talk on Monday

Hope you all had a great day

Neil

Wally

Do you have any suggestions for helping to keep us in the narrower target

levels? Another option is a redesign of the oximeters, or a simple shift of
3-5% for all values as in BOOST. This may produce better separation throughout, but is problematic at the high ranges.

With regards to great clinical care, we do not have any data as to the ideal
SpO2 ranges that we should target. No such data has ever been collected and
this was an aim of this trial. We need the ranges to be tested with the relevant outcomes, but I agree with the DSMC that we also need separation.

Subject: RE: re sat distribution data

Hi:

I think it is important that everyone is aware of usual sats in NICUs. Michele's data is helpful. The multicenter study I mentioned yesterday is
also helpful. Nonetheless, we should strive to provide great clinical care,
not just do great trials.

I agree that we want different O2 exposures but we must remember that in part, that differential exposure is best accomplished while the infants are
at a saturation 88-92%. I like Neil's idea of lower alarm levels but I suspect, it will reduce but not eliminate the problem.

I think it is important to compare our data with that of other trials such
as the BOOST one, which also show a high frequency of sats >95%.

Lets think all of this over.
Rose, can you ask Marie Ganz to provide us the actual percentage of time in
the various ranges for all of the infants (non corrected data) for the time
only in room air. She previously gave us in oxygen and overall. The room air
only will provide a ranges of SpO2 > 95% and we can look at this in interpreting the percent time > 96%.

I believe that we can probably move ahead with the trial and I am prepared
to argue for this.
In spite of this, have a peaceful and restful Thanksgiving
Neil

Wally
I agree with the goal of better SpO2 control but at present we don't know the ideal range – this makes any change in the study difficult apart from more education and better attention to alarms. Do you think we should change the alarm limit as previously suggested – 80% to 94%??

Neil:
The compliance in the Poets paper was better even when you look only at the clinical nurse. I think we must be sure we are doing the best trial possible. I think that in the future there will be O2 servocontrol systems in place. In the meantime, we could train clinicians in many clinical and physiological aspects of O2 sats such as importance of targets, baseline sats vs expected desats, etc

I think we should strongly endorse continuation of the trial but also need to consider specific improvements. I want to try more education of the bedside staff, closer supervision by the nuring leadership, help from RTs, and others.

Subject: RE: re sat distribution data

Hi Wally

The Poets study demonstrated compliance for a range of SpO2 from 87% to 96%. We don't know our percentage of time in this range. We will have more knowledge when we see the individual SpO2 data and even then because the values of 85% and 96% will be overrepresented, I am not sure that we will get all the answers.

I think that a 5% range is probably too small to hit with regularity in the majority of NICUs without a dedicated person doing nothing else. We could widen this maximal separation if we change the skew to go below 85%. We

were reluctant to go there before. There is really no new data to indicate that going lower is safer. In fact, there is essentially no data as large as the study database for true SpO2 values of 84% and less and 96% and greater. This study will provide the data as to whether any duration below or above these values is beneficial or harmful. I would like to push for lowering the alarm limits.

Another paradoxical thought as suggested by Maynard is that we decrease the averaging and alarm delays, so that the care teams are more quickly informed when infants go out of the narrow target range.

I am also not sure that we haven't created to different oxygen exposures. The two randomized groups of infants differ by 10% for the percent of time below 85%. This could be associated with a difference in oxygen exposure. In addition this difference could drive different outcomes which is exactly what we want to test.

However we only collect these values 3 times per day. We do have technology to collect the FiO2 continuously and we use this for some of our DR research. Should we try to do this for 10-20 infants in each range?

I will keep thinking on this till we talk on Monday

Hope you all had a great day

Neil

Thanks Wally

Would this be someone at the bedside or a person to assist with reviewing the monitor ranges etc. One concern that I have would be the reproducibility of using such an individual. While a number of studies have shown the value of servo control – most recently Poets study, It is doubtful that a manufacturer will develop such a device in view of the potential liability.

Let's keep thinking about other options

Neil:

A recent study of pulse oximetry by servocontrol or dedicated person showed extremely high compliance with the saturation targets. I believe it was 80-90%. I think we should consider adding resources to have a dedicated person achieve high compliance.

Wally

Do you have any suggestions for helping to keep us in the narrower target levels? Another option is a redesign of the oximeters, or a simple shift of 3-5% for all values as in BOOST. This may produce better separation throughout, but is problematic at the high ranges.

With regards to great clinical care, we do not have any data as to the ideal SpO2 ranges that we should target. No such data has ever been collected and this was an aim of this trial. We need the ranges to be tested with the relevant outcomes, but I agree with the DSMC that we also need separation.

Subject: RE: re sat distribution data

Hi:

I think it is important that everyone is aware of usual sats in NICUs. Michele's data is helpful. The multicenter study I mentioned yesterday is also helpful. Nonetheless, we should strive to provide great clinical care, not just do great trials.

I agree that we want different O2 exposures but we must remember that in part, that differential exposure is best accomplished while the infants are at a saturation 88-92%. I like Neil's idea of lower alarm levels but I suspect, it will reduce but not eliminate the problem.

I think it is important to compare our data with that of other trials such as the BOOST one, which also show a high frequency of sats >95%.

Subject: RE: re sat distribution data

Hello All

I agree with Ed's comments. In fact we wanted to create different oxygen exposures and the way to do this was to have different periods of time at different SpO2 levels, and it would appear that we have succeeded.

I am also uncertain why non blinded data was evaluated. Our previous comments were that some units were experiencing that the high alarms were not being set. We did not postulate that this was an issue for one or other arm of the trial, but rather a response to frequent alarms. It is the alarms that work to keep the babies in range.

Also we need to understand that the design of the algorithms was also to push the infants into the middle range. I will try to explain this. For an infant whose oximeter displays 88% to 92% when the actual SpO2 is 91% to 95%, as the true, SpO2 increases toward 95%, the display will increase to 95% to 96% and the alarm can be activated (with the appropriate time delay etc) at actual values of 94-95%. Thus this infant will alarm when the actual SpO2 is BELOW the upper limit of 95%. This will tend to keep the infant more within the desired target range. The same will happen for infants in the lower range, in that when their actual SpO2 is 87%, the display will show 85% and any further decrease will trigger the alarm.

In reviewing the DSMC comments I believe that our strategy moving forward should be as follows:

1. We should strenuously argue that the percent of time over 95% in NOT a safety issue as there is no antecedent

data that such SpO2s for such a duration, ie 35% > 95% are toxic. We would argue that this duration is actually lower than may be expected.

2. We would additionally hope that an analysis will show excessive time at 96% which actually may represent values from 93% to 96%
3. I would suggest that we change the low alarm to 80% and the high to 94%. This should push us toward the narrow targets
4. We need to rewrite the manual and protocol to clarify that we are aiming to produce different oxygen exposures using different SpO2 limits
5. I would fight vigorously to continue the trial as is, and re-evaluate the oximetry data after a further 100-200 infants
6. If we are forced to consider dropping the oximetry arm, then have all the Masimo oximeters converted to normal and continue to use them to collect the data about the actual SpO2 exposures of this population which will still be unique and incredibly useful in looking at durations of hyperoxia and hypoxia in the ELBW and their outcomes.

Please consider these suggestions and let me know your thoughts and suggestions

I would like to be prepared for our Monday call.

Have a great Thanksgiving

To: Duara, Shahnaz; Michele Walsh; Higgins, Rose; Finer, Neil; Donovan, Edward (DONOVAEF); Wally Carlo, M.D.; Rich, Wade; Newman, Nancy
Cc: Gantz, Marie; Poole, W. Kenneth
Subject: RE: RBC Non SUPPORT Saturation Data

The hours reported in the tables that the DSMC saw (and which you have now been sent) are for days on supplemental O2 only; so we have taken out days the infants are on room air (defined as FiO2=0.21 or Mode of Support=7 (No Support) as per SUPP05 or Oxygen=N or Highest Level of Support=7 (No Support) as per SUPP11). However, it is possible that there are times on the supplemental O2 days that the babies are actually on room air; but we have tried to exclude time on room air from the tables that the DSMC saw as best we could.

Thanks

Abhik

> > **Subject:** RBC Non SUPPORT Saturation Data
> >
> > Hi All!
> > As we suspected, the kids outside of the trial have sats even higher- at least at RB&C. We have downloaded the Massimo data on 9 non-SUpport kids enrolled in a desaturation study. These data are collected in an identical manner to the SUPPORT kids and meet all the other entry criteria except they are not randomized to an oxygen intervention. Five were on vents, 3 on cpap, and 1 in nasal cannula. Thus, they are managed under routine

conditions for our nursery which is stated as sat 90-95%.
It is important to note that this DOES include time when they are in room air. We will try to pull out the data for these patients and times- and reanalyze.
However, the SUPPORT data is also subject to that same bias for kids on RA vent, RA cpap, RA nc. Was the DSMC aware of this? Can RTI pull out the sats for these types of interventions?
To summarize the distribution:
> 95% sat - 56% (range 38-86)
90-95% sat - 26% (range 8-33%)
85-89% sat - 8% (range 2-13%)
< 85% sat - 11% (range 3-25%)
I am attachng the file here.
Michele

Hi,
happy Thanksgiving all
It is disturbing to enter the Thanksgiving on this sour note of the trial being suspended
I think that Neil is on target with his comments and proposed plan of action
This is at least the 4th time in the history of the Network that a trial has been interrupted or discontinued after an interim analysis. That in of itself is worth reporting. If you add the Kristi Watterberg trail to the mix that makes 5. Given the extraordinary effort to get the design and implementation of the trial correct, how can we avoid these interruptions in the future?
Regards
Avroy

Subject: RE: re sat distribution data
Date: Wednesday, November 23, 2005 2:12:11 PM

Hi,

The safety issue is hyperoxia, which is not possible even with a sat of 100% in 21% oxygen. With supplemental oxygen, its another story... limiting use of the Masimo (and indirectly the oximeter data collection) to periods of supplemental oxygen is a way to separate the 2 issues, but contamination of dumps with RA data may not be only problem. From what Abhik describes, RTI excluded all known RA days from the analysis, so the only way the data set could get contaminated would be if an 'oxygen' day was a misnomer, allowing inclusion of babies who spent most of the day in RA with a brief period of extra oxygen to be labeled 'oxygen'. Sats may be appropriate during the day to the level of support he/she is getting, but the dumps don't help us sort that out. Not being able to collect continuous FiO2 data simultaneously is the confounder. One way out would be to require significant numbers of hours (? > 12 h) of supplemental oxygen before a day can be labeled an 'oxygen' day - otherwise call it a RA day and forget about analyzing the dump for that day. It sounds arbitrary but so is our current approach.

Couldn't we turn the safety issue around and focus on the 100% sat value, since that is the value where hyperoxia could occur on supplemental oxygen? Spending 36% of the time with sats >95% is concerning only within context.

Happy Thanksgiving to all of you - I'm outta here !

Shahnaz

Subject: RE: re sat distribution data

Neil,

I've attached a table showing percent of time in each oximeter display range for infants on room air. Room air was defined as FiO2=0.21 or Mode of Support=7 (No Support) on SUPP05 or Oxygen=N or Highest Level of Support=7 (No Support) on SUPP11. Note that, for infants in the LOW oxygenation group, the display range of >95% includes actual SpO2 levels of 93-95%.

Our programmers are working on getting us the data for the actual >95% range broken out into finer units.

Hi Again
While we are it, we should ask RTI to look at the percentage for each SpO2 value over 95% ie percent at 96%, 97% 98% 99% and 100%. This will help especially with values at 100%. If there is an issue of the study

creating separate oxygen groups, then the analysis should be looking at the FiO2 exposure to see if we have created different oxygen exposures. I would favor mimimal analyses at this point and trial continuation, with perhaps a change in alarm limits. Let's think about all of this and try to talk on the phone next Monday Be well Neil

Subject: RE: re sat distribution data

Hi Michele and all
I have reviewed Abbot's abstract and he found that the SpO2 was > 95% for about 17% of the time. In addition the skew for correcting the stored values in the oximeter back to real unaltered values is such that for the group in high range ie 88% to 92% is actually 91% to 95%, in the process of correcting, there are a number of real, actual SpO2 values - 93%, 94%, 95% and 96% which are all converted to a display value of 96% because of rounding of decimal points (The Masimo cannot display decimals and we had agreed to this formula as 96% cannot be linked to 4 different actual SpO2 values).
We were aware of this, and used this because we wished to maintain the separation over the widest range. This will represent a problem in reviewing the unskewed data in that there will be an over-representation of values at 96% for the high range infants and 85% for the low range infants.
RTI in converting the data back to "normal" will only see a 96% value for any value of 93%, 94% or 95% or 96% in the 91-95% target infants, and thus we will find a much increased percentage for the actual value of 96% after data conversion, as was done.
We therefore need to look at the value of 96% separately, as we do for 85% We need to understand that values of 96% after conversion will represent actual values of anywhere from 93 to 96%.
However we had agreed that this would not be realistic so that fractions were assigned most of which if corrected to a full integer would read 96%.

This now raises the issue of the study intent and design. We did not design the trial to produce different SpO2s but rather to use the SpO2 to create different oxygen exposures. To my knowledge we did not analyze the FiO2 for the 2 groups. In addition we do not know at present if the % of time > 95% and < 85% are different than what is normally experienced for ELBW infants. We need to know the percentage of time at the single value of 96% and probably similarly at 85%. Some values of 96% will actually represent values that should be within the 92% to 95% range, but we will have no ability to know this. I believe that if we achieve close to 60% within 85% to 95% with the current skews, that we will achieve FiO2 differences.
STOP ROP kept the high range infants at > 95% for > 90% of the time. I am uncertain as to the known risk of any value for SpO2 > 95% below 90%. I also believe that we may increase our time in the narrow and broader ranges by lowering the low alarm to 80% and the high alarm to 94%. Lets think all of this over. Rose, can you ask Marie Ganz to provide us the

actual percentage of time in the various ranges for all of the infants (non corrected data) for the time only in room air. She previously gave us in oxygen and overall. The room air only will provide a ranges of SpO2 > 95% and we can look at this in interpreting the percent time > 96%.

I believe that we can probably move ahead with the trial and I am prepared to argue for this. In spite of this, have a peaceful and restful Thanksgiving Neil

Rose,

David could probably do either one. On November 30, he has a meeting already scheduled to start at 7:15am and could be on the conference call for 45 minutes. Does that give you enough time?

December 1 and 2, David is out of the office for (b) (6) . Since the conference call will start very early our time, that may also be a possibility.

I most likely will talk to him later today and could ask him, but you probably want to get this set before then. I would say to go with whatever time works best for everyone else and I will add it to David's calendar.

Thanks,
Lisa

Date: Wednesday, November 23, 2005 1:15:15 PM

Abhik: The issue is when kids are on RA but still on a vent, or on RA but still on cpapor nc, we are still collecting saturation data but have no ability to lower the sat by weaning FiO2- these would have to be excluded from the data for the DSMC in order for their conclusion to be correct that the babes are at risk from inappropriately high saturation.
Another alternative for the group to consider is to take kids off the sat monitor when in RA regardless of the pressure support- I recognize we have been around this track before- but perhaps we need to reconsider.
REgards, Michele

Subject: RE: RBC Non SUPPORT Saturation Data

The hours reported in the tables that the DSMC saw (and which you have now been sent) are for days on supplemental O2 only; so we have taken out days the infants are on room air (defined as FiO2=0.21 or Mode of Support=7 (No Support) as per SUPP05 or Oxygen=N or Highest Level of Support=7 (No Support) as per SUPP11). However, it is possible that there are times on the supplemental O2 days that the babies are actually on room air; but we have tried to exclude time on room air from the tables that the DSMC saw as best we could.

Thanks

Abhik

Hi Michele et al;

I agree that its going to be really important to weed out the RA+vent, cpap or cannula kids, if possible, because they appropriately add high sats to the mix. We don't use Masimos clinically so I don't have additional clinical data that we could add to the mix.

Subject: RBC Non SUPPORT Saturation Data

Hi All!
As we suspected, the kids outside of the trial have sats even higher- at least at RB&C.
We have downloaded the Massimo data on 9 non-SUpport kids enrolled in a desaturation study. These data are collected in an identical manner to the SUPPORT kids and meet all the other entry criteria except they are not randomized to an oxygen intervention. Five were on vents, 3 on cpap, and 1 in nasal cannula. Thus, they are managed under routine conditions for our nursery which is stated as sat 90-95%.
It is important to note that this DOES include time when they are in room air. We will try to pull out the data for these patients and times- and reanalyze.
However, the SUPPORT data is also subject to that same bias for kids on RA vent, RA cpap, RA nc. Was the DSMC aware of this? Can RTI pull out the sats for these types of interventions?
To summarize the distribution:
> 95% sat - 56% (range 38-86)
90-95% sat - 26% (range 8-33%)
85-89% sat - 8% (range 2-13%)
< 85% sat - 11% (range 3-25%)
I am attachng the file here.
Michele

Hi All!
As we suspected, the kids outside of the trial have sats even higher- at least at RB&C.
We have downloaded the Massimo data on 9 non-SUpport kids enrolled in a desaturation study. These data are collected in an identical manner to the SUPPORT kids and meet all the other entry criteria except they are not randomized to an oxygen intervention. Five were on vents, 3 on cpap, and 1 in nasal cannula. Thus, they are managed under routine conditions for our nursery which is stated as sat 90-95%.
It is important to note that this DOES include time when they are in room air. We will try to pull out the data for these patients and times- and reanalyze.
However, the SUPPORT data is also subject to that same bias for kids on RA vent, RA cpap, RA nc. Was the DSMC aware of this? Can RTI pull out the sats for these types of interventions?
To summarize the distribution:
> 95% sat - 56% (range 38-86)
90-95% sat - 26% (range 8-33%)
85-89% sat - 8% (range 2-13%)
< 85% sat - 11% (range 3-25%)
I am attachng the file here.
Michele

Don't you guys ever take a break
happy holidays
We have been pelted with snow - it has become a Thanksgiving tradition
One that I would readily surrender
Wally, in the real world, which this trial was designed for in the long run, you cannot demand a specialist at the bedside to monitor the saturation monitor.
We need to modify the study to separate the groups
Av

Thanks Wally

Would this be someone at the bedside or a person to assist with reviewing the monitor ranges etc. One concern that I have would be the reproducibility of using such an individual. While a number of studies have shown the value of servo control – most recently Poets study, It is doubtful that a manufacturer will develop such a device in view of the potential liability.

Let's keep thinking about other options

Neil:

A recent study of pulse oximetry by servocontrol or dedicated person showed extremely high compliance with the saturation targets. I believe it was 80-90%. I think we should consider adding resources to have a dedicated person achieve high compliance.

Wally

Do you have any suggestions for helping to keep us in the narrower target levels? Another option is a redesign of the oximeters, or a simple shift of 3-5% for all values as in BOOST. This may produce better separation throughout, but is problematic at the high ranges.

With regards to great clinical care, we do not have any data as to the ideal SpO2 ranges that we should target. No such data has ever been collected and this was an aim of this trial. We need the ranges to be tested with the relevant outcomes, but I agree with the DSMC that we also need separation.

Subject: RE: re sat distribution data

Hi:
I think it is important that everyone is aware of usual sats in NICUs. Michele's data is helpful. The multicenter study I mentioned yesterday is also helpful. Nonetheless, we should strive to provide great clinical care, not just do great trials.

I agree that we want different O2 exposures but we must remember that in part, that differential exposure is best accomplished while the infants are at a saturation 88-92%. I like Neil's idea of lower alarm levels but I suspect, it will reduce but not eliminate the problem.

I think it is important to compare our data with that of other trials such as the BOOST one, which also

show a high frequency of sats >95%.

Subject: RE: re sat distribution data

Hello All

I agree with Ed's comments. In fact we wanted to create different oxygen exposures and the way to do this was to have different periods of time at different SpO2 levels, and it would appear that we have succeeded.

I am also uncertain why non blinded data was evaluated. Our previous comments were that some units were experiencing that the high alarms were not being set. We did not postulate that this was an issue for one or other arm of the trial, but rather a response to frequent alarms. It is the alarms that work to keep the babies in range.

Also we need to understand that the design of the algorithms was also to push the infants into the middle range. I will try to explain this. For an infant whose oximeter displays 88% to 92% when the actual SpO2 is 91% to 95%, as the true, SpO2 increases toward 95%, the display will increase to 95% to 96% and the alarm can be activated (with the appropriate time delay etc) at actual values of 94-95%. Thus this infant will alarm when the actual SpO2 is BELOW the upper limit of 95%. This will tend to keep the infant more within the desired target range. The same will happen for infants in the lower range, in that when their actual SpO2 is 87%, the display will show 85% and any further decrease will trigger the alarm.

In reviewing the DSMC comments I believe that our strategy moving forward should be as follows:

1. We should strenuously argue that the percent of time over 95% in NOT a safety issue as there is no antecedent data that such SpO2s for such a duration, ie 35% > 95% are toxic. We would argue that this duration is actually lower than may be expected.
2. We would additionally hope that an analysis will show excessive time at 96% which actually may represent values from 93% to 96%
3. I would suggest that we change the low alarm to 80% and the high to 94%. This should push us toward the narrow targets
4. We need to rewrite the manual and protocol to clarify that we are aiming to produce different oxygen exposures using different SpO2 limits
5. I would fight vigorously to continue the trial as is, and re-evaluate the oximetry data after a further 100-200 infants
6. If we are forced to consider dropping the oximetry arm, then have all the Masimo oximeters converted to normal and continue to use them to collect the data about the actual SpO2 exposures of this population which will still be unique and incredibly useful in looking at durations of hyperoxia and hypoxia in the ELBW and their outcomes.

Please consider these suggestions and let me know your thoughts and suggestions

I would like to be prepared for our Monday call.

Have a great Thanksgiving

Neil

Do we have any details on this issue?
What I understand is that there is a concern about exposure to high O2 sat disproportionately in one arm? If it's the "high" arm, then this is the purpose of the study, i.e. to see if decreasing oxygen exposure reduces BPD and ROP. Am I missing the boat? When are we going to see the actual concerns of the DSMC?

Hi Michele and all
I have reviewed Abbot's abstract and he found that the SpO2 was > 95% for

about 17% of the time.
In addition the skew for correcting the stored values in the oximeter back to real unaltered values is such that for the group in high range ie 88% to 92% is actually 91% to 95%, in the process of correcting, there are a number of real, actual SpO2 values - 93%, 94%, 95% and 96% which are all converted to a display value of 96% because of rounding of decimal points (The Masimo cannot display decimals and we had agreed to this formula as 96% cannot be linked to 4 different actual SpO2 values).
We were aware of this, and used this because we wished to maintain the separation over the widest range. This will represent a problem in reviewing the unskewed data in that there will be an over-representation of values at 96% for the high range infants and 85% for the low range infants.
RTI in converting the data back to "normal" will only see a 96% value for any value of 93%, 94% or 95% or 96% in the 91-95% target infants, and thus we will find a much increased percentage for the actual value of 96% after data conversion, as was done.
We therefore need to look at the value of 96% separately, as we do for 85%
We need to understand that values of 96% after conversion will represent actual values of anywhere from 93 to 96%.
However we had agreed that this would not be realistic so that fractions were assigned most of which if corrected to a full integer would read 96%.

This now raises the issue of the study intent and design. We did not design the trial to produce different SpO2s but rather to use the SpO2 to create different oxygen exposures. To my knowledge we did not analyze the FiO2 for the 2 groups. In addition we do not know at present if the % of time > 95% and < 85% are different than what is normally experienced for ELBW infants.
We need to know the percentage of time at the single value of 96% and probably similarly at 85%. Some values of 96% will actually represent values that should be within the 92% to 95% range, but we will have no ability to know this.
I believe that if we achieve close to 60% within 85% to 95% with the current skews, that we will achieve FiO2 differences.
STOP ROP kept the high range infants at > 95% for > 90% of the time. I am uncertain as to the known risk of any value for SpO2 > 95% below 90%.
I also believe that we may increase our time in the narrow and broader ranges by lowering the low alarm to 80% and the high alarm to 94%.
Lets think all of this over.
Rose, can you ask Marie Ganz to provide us the actual percentage of time in the various ranges for all of the infants (non corrected data) for the time only in room air. She previously gave us in oxygen and overall. The room air only will provide a ranges of SpO2 > 95% and we can look at this in interpreting the percent time > 96%.

I believe that we can probably move ahead with the trial and I am prepared to argue for this.
In spite of this, have a peaceful and restful Thanksgiving
Neil

Subject FW: SUPPORT Trial

Dear All,

As you all have been informed by Dr. Higgins, the SUPPORT Trial has been temporarily suspended effective November 22, 2005. Enclosed, as an attachment, is a memo describing the rationale and supporting data for suspending the trial. The SUPPORT Subcommittee plans to meet, by phone, early next week and their recommendations will be sent to the Steering Committee. A Steering Committee call will then be scheduled to discuss these recommendations.

For patients currently enrolled on the study protocol, they can remain on the protocol. Strict adherence to the saturations targets must be emphasized. For infants enrolled in the MRI secondary study, they can have their assessments and if patients have already been enrolled in the SUPPORT primary study, they can be approached for the MRI secondary study.

Thanks.

Betty

Hi Again
While we are it, we should ask RTI to look at the percentage for each SpO2 value over 95% ie percent at 96%, 97% 98% 99% and 100%. This will help especially with values at 100%. If there is an issue of the study creating separate oxygen groups, then the analysis should be looking at the FiO2 exposure to see if we have created different oxygen exposures. I would favor mimimal analyses at this point and trial continuation, with perhaps a change in alarm limits. Let's think about all of this and try to talk on the phone next Monday Be well Neil

Hi Michele and all
I have reviewed Abbot's abstract and he found that the SpO2 was > 95% for about 17% of the time. In addition the skew for correcting the stored values in the oximeter back to real unaltered values is such that for the group in high range ie 88% to 92% is actually 91% to 95%, in the process of correcting, there are a number of real, actual SpO2 values - 93%, 94%, 95% and 96% which are all converted to a display value of 96% because of rounding of decimal points (The Masimo cannot display decimals and we had agreed to this formula as 96% cannot be linked to 4

I just want to make sure we are all aware that many studies looking at sats/PaO2 have shown high sats routinely used in preemies. There was one abstract at PAS of the multicenter study on pulse ox monitoring by Cindy Cole and collaborators showing the high sats maintained in the US. We were the center with the lowest sats and our average was 92% even though we aim for 90%. In one of the initial benchmarking pilot data collection, I think similar findings were observed on day 1 (with PaO2s, Michele: Correct my terrible memory). However, it will be good to be aware of the problem and try to address is. wally

Hi Again
While we are it, we should ask RTI to look at the percentage for each SpO2 value over 95% ie percent at 96%, 97% 98% 99% and 100%. This will help especially with values at 100%.
If there is an issue of the study creating separate oxygen groups, then the analysis should be looking at the FiO2 exposure to see if we have created different oxygen exposures.
I would favor mimimal analyses at this point and trial continuation, with perhaps a change in alarm limits.
Let's think about all of this and try to talk on the phone next Monday
Be well Neil

Subject: RE: re sat distribution data

Hi Michele and all
I have reviewed Abbot's abstract and he found that the SpO2 was > 95% for about 17% of the time.
In addition the skew for correcting the stored values in the oximeter back to real unaltered values is such that for the group in high range ie 88% to 92% is actually 91% to 95%, in the process of correcting, there are a number of real, actual SpO2 values - 93%, 94%, 95% and 96% which are all converted to a display value of 96% because of rounding of decimal points (The Masimo cannot display decimals and we had agreed to

this formula as 96% cannot be linked to 4 different actual SpO2 values).

We were aware of this, and used this because we wished to maintain the separation over the widest range. This will represent a problem in reviewing the unskewed data in that there will be an over-representation of values at 96% for the high range infants and 85% for the low range infants.
RTI in converting the data back to "normal" will only see a 96% value for any value of 93%, 94% or 95% or 96% in the 91-95% target infants, and thus we will find a much increased percentage for the actual value of 96% after data conversion, as was done.
We therefore need to look at the value of 96% separately, as we do for 85% We need to understand that values of 96% after conversion will represent actual values of anywhere from 93 to 96%.
However we had agreed that this would not be realistic so that fractions were assigned most of which if corrected to a full integer would read 96%.

This now raises the issue of the study intent and design. We did not design the trial to produce different SpO2s but rather to use the SpO2 to create different oxygen exposures. To my knowledge we did not analyze the FiO2 for the 2 groups. In addition we do not know at present if the % of time > 95% and < 85% are different than what is normally experienced for ELBW infants.
We need to know the percentage of time at the single value of 96% and probably similarly at 85%. Some values of 96% will actually represent values that should be within the 92% to 95% range, but we will have no ability to know this.
I believe that if we achieve close to 60% within 85% to 95% with the current skews, that we will achieve FiO2 differences.
STOP ROP kept the high range infants at > 95% for > 90% of the time. I am uncertain as to the known risk of any value for SpO2 > 95% below 90%.
I also believe that we may increase our time in the narrow and broader ranges by lowering the low alarm to 80% and the high alarm to 94%.
Lets think all of this over.
Rose, can you ask Marie Ganz to provide us the actual percentage of time in the various ranges for all of the infants (non corrected data) for the time only in room air. She previously gave us in oxygen and overall.
The room air only will provide a ranges of SpO2 > 95% and we can look at this in interpreting the percent time > 96%.

I believe that we can probably move ahead with the trial and I am prepared to argue for this.
In spite of this, have a peaceful and restful Thanksgiving Neil

Subject:	Fwd: Motor Function NF05 --Some Issues Not Yet Resolved
Date:	Monday, November 21, 2005 1:55:59 PM

I sent this on the 12th but am not sure if any of you got it, since I received no feedback. Hate to beat a dead horse, but doesn't appear that any of these issues are addressed or resolved in the final version of the manual Carolyn just sent out.

Furthermore, in going back over case 3 from our interrator session, it appears we labeled a case of "suspect" increased tone in ankles only, combined with "toe walking", as "mild diplegia". Even if we accept the gait as functional but not fluent, there was not a "definite" tone abnormality. Though our overall definition of CP requires definite tone abnormality, it may be worth reiterating this in the descriptions for the specific types of spastic CP in question 9c. Secondly, if the amount of toe walking displayed by this patient, which I think we debated about in the interrator session, is going to be sufficient to label the child either as mild diplegia (when definite tone abnormality is also present) or as "CP otherwise unclassified" (if tone normal), then I think we need a clearer definition of what constitutes toe walking. Just as brief periods up on toes do not constitute an abnormal positive support reaction (in fact, one must remain up on toes for 30 secs), I'm not sure that brief/intermittent periods up on toes when walking are sufficient to indicate non-fluent gait, never mind CP--especially when the child intermittently comes down off toes and even shows ability to intermittently without rising up on toes. In any case, the instruction for question 9b2 (Hypertonia) indicates that toe walking with normal angles should be coded as "9 Other neurological abnormality in Section B"; if this is intended to refer to the revised 9c10 "Cerebral Palsy Otherwise Unclassified" then the reference needs to be corrected; but as I indicated in #5 below, I still think it is debatable whether toe walking without definite tone abnormality meets our two criteria definition of CP; and think, if it can truly be considered "isolated" abnormal toe walking, then it would be better classified as 9b3--other abnormal (non-CP).

>>> Roy Heyne 11/12/05 4:01 PM >>>
As we were going over the developmental cases on the DVD from our interrator session, several questions arose concerning the revised wording we had discussed during our last conference call.

1) Upper Extremity Tone: Betty's case (#5) was assessed to have suspect decreased tone; but in looking back at our revised operations manual definition on 10-11, we do not address decreased tone at all, either definite or suspect.

2) Lower limb function gait: Dee's case (#1) was assessed to have no independent walking (choice 4 on question 6c), but if in fact the child was able to cruise, or walk with examiner assistance ("hands held") for balance only, we wondered whether she should be rated at level 3, instead, since the previous definition of moderate CP on 10-20 of the manual indicated that "assistive devices include walkers, AFOs, hand(s) held, ... cruising". I don't recall addressing that issue in our last conference call, but I think this case illustrates the need to do so.

3) Speaking of GMF, my staff also raised some questions regarding the correspondence between Lowe limb function gait (LLFG) levels and GMF levels. It seems fairly apparent that LLFG code 1 corresponds to GMF 1 and LLFG 2 to GMF Possible 1. But LLFG 3 could map to either GMF 1 or 2, depending on how we define "device" in the LLFG scheme, and how broadly we interpret "holding on to furniture" in the Palisano wording, and specifically whether we extend the latter so that it covers the same range of assisted modes as "device" in our former definition of moderate CP. This will also determine whether GMF 1 maps to Mild CP, as the current draft has it, or to Moderate CP, if the latter extends down to include children who can cruise, etc. but cannot walk without some "device" assistance.

4) One of our group (not me for a change) wondered why there are two apparent paths to Level 2 on NF05a? They asked why the decision box "Sits hands free for play" doesn't also include all three items in the box to its right, since a child really has to be able to perform all 4 items to qualify for Level 1. Inability to do any of the 4 motor tasks pushes one down the decision tree to Level 2 or greater.

5) In our discussion of our new two-criteria definition of CP, several of the staff questioned how a toe-walker with

normal angles meets both criteria, specifically how (s)he fulfills the abnormality of classical neuro exam element. They thought it was circular/redundant to consider dysfluent gait both a functional disorder and a neuro abnormality. In any case, they thought it would be more appropriate to classify this as other abnormal under the non-CP classification set rather than as other CP.

6) Speaking of the latter, I could not tell from my notes what we finally decided to include under revised #9. Were we going to restrict this to "mixed" CP in the sense of some combination of types 1-8, for example double hemiplegia or asymmetric quad, or just to a combination of spastic CP and dyskinetic CP. And where were we going to put the dyspraxia and maladroit: under 10 (not otherwise classifiable), or, perhaps better yet, under non-CP other? And where did we decide to put facial palsy and vocal cord paralysis?

Subject:	Coordinator Availability for Breathing Outcomes Interview Training
Date:	Thursday, November 17, 2005 5:11:30 PM
Attachments:	SUPPORT BO Protocol 11-17.doc

Dear Follow-up Coordinators,
Attached is the Breathing Outcomes Protocol in case anyone needs it for IRB submission. The Forms and Manual will be distributed in the next few days with the changes discussed during today's call. Please let me know your availability for each of the times below for training to conduct the Breathing Outcomes questionnaires:

Tuesday December 6 from 2-4pm
Wednesday December 7 from 2-4pm
Friday December 9 from 2-4pm
Monday December 13 from 2-4pm

We will most likely have two separate trainings so that everyone will be able to participate. Please let me know if you have any questions.

Thanks, Jamie

TABLE OF CONTENTS

Study Protocol

ABSTRACT

Statement of Problem Premature infants have a greater risk of recurrent wheezing and chronic cough and greater need for pulmonary care in early childhood than term infants (1-11). Although Chronic Lung Disease (CLD) is a risk factor, the etiology of symptomatic airway dysfunction, defined hereafter as recurrent wheezing and/or chronic cough, in formerly premature infants is not known.

Hypotheses The goal of this clinical project is to understand better the antecedents of symptomatic airway dysfunction among preterm infants during early childhood by evaluating the effect of treatment with different levels of targeted oxygen saturation in the immediate neonatal period. **The overarching hypothesis is that premature infants exposed to supplemental oxygen suffer oxidant stress in the lung in the immediate newborn period that results in impaired airway growth and development. These airway changes predispose premature infants to greater airway dysfunction and respiratory symptoms when challenged with subsequent environmental or infectious exposures.**

Hypothesis #1- Relative to infants managed with a higher SpO2 range, infants who are managed with a lower targeted SpO2 range will have less symptomatic airway dysfunction and reduced need for outpatient pulmonary care in the first 18-22 months' corrected age (CA), whether they develop CLD or not.

Hypothesis #2- Relative to infants managed with prophylactic surfactant and conventional ventilation, infants who are managed with the early use of CPAP and a permissive ventilator strategy will have less symptomatic airway dysfunction and reduced need for outpatient pulmonary care in the first 18-22 months' CA, whether they develop CLD or not.

Design

This study is a longitudinal follow-up of infants enrolled in the SUPPORT Trial to determine the effect of lower targeted oxygen saturation ranges and more aggressive use of CPAP on the incidence of symptomatic airway dysfunction and volume of outpatient pulmonary care in the first 18-22 months' CA.

Definition of outcomes:

A) Parental Report Symptomatic Airway Dysfunction Defined as Recurrent Wheezing or Chronic Cough
B) Parental Report of Physician Diagnosed Wheezing
C) Volume of Outpatient Pulmonary Care including number of pulmonary medications, office and emergency room visits and re-hospitalizations for respiratory illnesses.

Ascertainment of outcomes:

Outcomes will be measured at 4 time points in the first 18-22 months' CA as follows:

1. NICU discharge -baseline interview at to obtain family and environmental history
2. Six months' CA - telephone or face to face interview to ascertain incidence of symptomatic airway dysfunction and obtain interval history of need for pulmonary care.
3. Twelve months' CA - telephone or face to face interview as at 6 months'
4. 18-22 months' CA- Prior to or as part of the NICHD follow-up clinic visit, a telephone or face to face interview will be conducted to ascertain incidence of symptomatic airway dysfunction and obtain history of need for pulmonary care.

Anticipated Results

We anticipate that, for infants who develop CLD and those who do not, treatment with a lower vs. higher targeted oxygen saturation range will have less symptomatic airway dysfunction and less need for outpatient pulmonary care in the first 18-22 months' CA. We also anticipate that greater use of CPAP compared with conventional management will be associated with less symptomatic airway dysfunction.

Benefits and Risks

The proposed SUPPORT Breathing Outcomes Study will directly measure symptomatic airway dysfunction and outpatient pulmonary morbidity in infants treated with either a higher vs. lower targeted oxygen saturation. These data will provide important insight into the effect of different levels of supplemental oxygen exposure on airway growth and development in formerly premature infants. In addition to creating a potential model for outpatient pulmonary follow up, the proposed follow on study may improve follow up at the 18-22 month NICHD visit by maintaining contact with families during the interval between NICU discharge and the neurodevelopmental follow up visit. We anticipate no risk to patients enrolled in this observational follow-up study.

B. STATEMENT OF THE PROBLEM

Premature infants have a greater risk for recurrent wheezing, chronic cough and more need for pulmonary care in early childhood than term infants(1-11). Although Chronic Lung Disease (CLD) is a risk factor, the etiology of symptomatic airway dysfunction, defined hereafter as recurrent wheezing and/or chronic cough, in formerly premature infants is not known.

C. HYPOTHESES

The overarching hypothesis is that premature infants exposed to supplemental oxygen and, to a lesser extent, mechanical ventilation, in the immediate neonatal period suffer oxidant stress in the lung that results in impaired airway growth and development. These airway changes predispose premature infants to greater airway dysfunction, respiratory symptoms and need for pulmonary care when challenged with subsequent environmental or infectious exposures.

Specific Hypotheses:

Hypothesis #1- We hypothesize that relative to infants managed with a higher SpO2 range, infants managed with a lower SpO2 range will have less frequent episodes of symptomatic airway dysfunction and reduced need for outpatient pulmonary care at 18-22 months' CA.

Hypothesis #2- We hypothesize that relative to infants managed with prophylactic surfactant and conventional ventilation, infants managed with early CPAP and permissive ventilator strategy will have less frequent episodes of symptomatic airway dysfunction and reduced need for outpatient pulmonary care in the first 18-22 months' CA.

Hypothesis #3- We hypothesize that **among infants with CLD**, infants managed with a lower SpO2 range relative to those managed with a higher SpO2 target range and infants managed with early CPAP and permissive ventilator strategy compared with those managed with prophylactic surfactant and conventional ventilation will have less frequent episodes of symptomatic airway dysfunction and reduced need for outpatient pulmonary care during the first 18-22 months' CA.

Hypothesis #4- We hypothesize that **among infants without CLD**, infants managed with a lower SpO2 range relative to those managed with a higher SpO2 target range and infants managed with early CPAP and permissive ventilator strategy compared with those managed with prophylactic surfactant and conventional ventilation will have less frequent episodes of symptomatic airway dysfunction and reduced need for outpatient pulmonary care during the first 18-22 months' CA.

D. SPECIFIC AIMS

The goal of this project is to understand better the etiology of symptomatic airway dysfunction among formerly premature infants during early childhood by examining the interaction of oxygen exposure (targeted SpO2 range), surfactant therapy and early nasal CPAP in the newborn period.

SA#1 - Measure the effect of lower vs. higher targeted SpO2 on the incidence of symptomatic airway dysfunction and volume of outpatient pulmonary care among infants born $24^{0/7}$ - $27^{6/7}$ weeks' gestation during the first 18-22 months' CA.

SA#2 - Measure the effect of early CPAP and permissive ventilator strategy compared with prophylactic surfactant and traditional ventilator strategy on the incidence of symptomatic airway dysfunction and volume of outpatient pulmonary care among infants born 24-27 weeks' gestation during the first 18-22 months' CA.

SA#3 – Among infants who develop CLD, determine whether CLD is milder in infants managed with low compared with high targeted SpO2 by measuring incidence of symptomatic airway dysfunction and volume of outpatient pulmonary care. A similar analysis will be performed by SUPPORT Trial ventilatory strategy assignment, i.e. early CPAP and permissive ventilation compared with prophylactic surfactant and traditional ventilation.

SA#4 – Among infants who do not develop CLD, determine whether pulmonary outcome is better for infants managed with a low compared with high targeted SpO2 range by measuring incidence of symptomatic airway dysfunction and need for outpatient pulmonary care. A similar analysis will be performed by SUPPORT Trial ventilatory strategy assignment, i.e. early CPAP and permissive ventilation compared with prophylactic surfactant and traditional ventilation.

E. RATIONALE/JUSTIFICATION

Although synergy in producing airway injury may exist between oxygen toxicity and mechanical forces applied to the lung, animal and human data suggest that exposure to high concentrations of supplemental oxygen alone is sufficient to cause airway narrowing and greater airway dysfunction when exposed to subsequent environmental or infectious challenges. Understanding the relative contributions of oxygen toxicity and mechanical forces on airway growth and development may facilitate development of targeted therapies for preventing or reducing symptomatic airway dysfunction in premature infants.

Why measure symptomatic airway dysfunction and outpatient pulmonary care as an outcome from a clinical NICU interventional trial?

1) Important information will be available on the effect of oxidant gas exposure on airway development and later symptomatic airway dysfunction. Exposure to oxidant gas has been causally linked with later wheezing. Existing data on the relationship between supplemental oxygen therapy and wheezing come from longitudinal cohort studies, a design that suffers from intrinsic limitations that make controlling for potential confounders of respiratory outcome difficult. By randomizing infants to higher vs. lower target saturation ranges, and thereby presumably higher or lower concentrations of inspired oxygen, *the SUPPORT Trial creates a unique, and perhaps the only, opportunity to evaluate the effect of different levels of supplemental oxygen on subsequent symptomatic airway dysfunction and need for outpatient pulmonary care after NICU discharge.*
2) Using clinical measures of outpatient pulmonary morbidity, the effect of NICU based respiratory interventions on respiratory health and need for outpatient medical care can be directly quantified, allowing assessment of whether infants both with and without CLD have improved pulmonary health as a result of the study intervention.
3) The incidence of CLD, defined as an oxygen requirement at 36 weeks' PMA, is an incomplete measure of pulmonary outcome in formerly premature infants during early infancy. CLD as defined above reflects alveolar gas diffusion and NICU oxygen needs. However, outpatient pulmonary morbidity for formerly premature infants is often airway related, involving wheezing either as a primary symptom such as bronchiolitis or as a complicating symptom of lower respiratory tract infection such as pneumonia. The studies proposed here will directly measure the effect of a randomized NICU-based clinical intervention on symptomatic airway dysfunction and outpatient pulmonary morbidity.
4) The risk of a negative trial is reduced. Because the diagnosis of CLD does not completely predict need for outpatient pulmonary care, clinically significant improvements in pulmonary morbidity may occur with minimal or no change in the incidence of CLD. This result has occurred in other interventional trials in which no difference in CLD were observed (12).
5) At present, there is no standard way to measure symptomatic airway dysfunction in premature infants in NICHD pulmonary intervention trials. There is need for a better measure to assess clinical pulmonary outcome to recognize and promote therapies that reduce need for outpatient care of former extremely premature infants.

F. BACKGROUND / PREVIOUS STUDIES

Recurrent Wheezing In Preterm Infants is a Significant Public Health Problem

Outpatient pulmonary morbidity, especially recurrent wheezing and need for outpatient pulmonary care, is an understudied but clinically important outcome measure for former premature infants with and without CLD. Infants born weighing < 1500 grams (very low birth weight, VLBW) and especially infants born weighing < 1000 grams are at increased risk for small airway narrowing, airway hyperreactivity, wheezing, and nighttime cough (1-11). Up to 30-40% of formerly extremely premature infants have episodes of wheezing after NICU discharge

with many requiring bronchodilators and frequent health care visits. Up to 40-50% of premature infants require re-hospitalization, mostly for treatment of respiratory illnesses (9;12;13). In analysis of cross sectional data from the National Maternal Infant Health Survey and 1991 Longitudinal Follow up Survey, the prevalence of asthma-like recurrent wheezing varied markedly with birth weight. Infants with normal birth weight (NBW, > 2500 grams) had a 6.7% prevalence of asthma compared to 10.9% of low birth weight infants (LBW, 1500-2499 grams) and 21.9% for VLBW (14). Mean per capita asthma related costs have been estimated to be 5 times greater for VLBW compared with NBW infants. The net effect is that VLBW infants, who comprise 2% of asthma patients, consume up to 7% of asthma-related therapy costs (14).

Animal Studies

Animal studies suggest that exposure of the premature lung to hyperoxia (without concomitant mechanical ventilation) for relatively brief periods is sufficient to cause airway remodeling and smooth muscle changes that predispose toward airway narrowing and hyperreactivity to subsequent environmental challenges (15-18). In a rhesus monkey model of asthma, Schlegle et al. exposed infant monkeys to repeated cycles of inhaled House Dust Mite Allergen (HDMA), ozone or filtered air. While repeated exposure to either ozone or HDMA had mild effects, exposure to cycles of ozone followed by HDMA resulted in asthma like changes with significant increases in serum IgE, serum histamine, peripheral eosinophilia and greater airway reactivity. Using supplemental oxygen rather than the stronger oxidant ozone, Schulman et al. found that exposure of newborn guinea pigs to 70% oxygen for 96 hours resulted in airway hyperreactivity at 2 and 9 days after the cessation of oxygen. In cell models, intracellular glutathione buffers airway cells against oxidant injury during hyperoxia (19;20). Although the critical period for lung development is comparatively brief in laboratory animals compared with human infants, the duration of hyperoxic exposure (and risk of oxygen toxicity) for treatment of neonatal lung disease may extend for much longer periods in premature infants known to be deficient in anti-oxidant systems such as intracellular glutathione.

Premature Infants <u>With CLD</u> Are At Greatest Risk For Airway Dysfunction

Among premature infants, infants with bronchopulmonary dysplasia (BPD) are at highest risk for poor pulmonary outcome after NICU discharge. Infants with CLD have small airway compromise with decreased forced expiratory flow velocities, airway hyperreactivity, and increased functional residual volume suggesting airway obstruction (2;5;9;21-24). In a pulmonary follow up of infants with RDS or BPD, De Klein et al. found infants with BPD had reduced FEV1 at baseline while infants with RDS but not BPD had significant improvements in FEV1 following bronchodilator therapy. In this study, a history of recurrent wheezing predicted abnormal pulmonary function (25). In a recent study of infants with CLD, Robin et al. found that 50% of infants with CLD had symptoms of recurrent wheezing and 35% showed significant airway responsiveness to bronchodilators, evidenced by a 24% increase in forced expiratory flow velocity at 75% of expired forced vital capacity (FEF_{75}). This study demonstrated the relationship between recurrent wheezing as a clinical symptom and the physiologic measurement of airway obstruction. Infants with CLD and a history of recurrent wheezing showed greater hyperinflation, expiratory flow limitation and airway responsiveness to albuterol compared to those without a history of recurrent wheezing (24).

Premature Infants <u>Without CLD</u> Have Significant Airway Dysfunction

Among VLBW infants who do not develop CLD, several studies of pulmonary outcome have found an association between neonatal oxygen exposure and increased prevalence of expiratory flow dysfunction and airway hyperreactivity (4;11;26-29). Some authors attribute reductions in airway function to intrinsically small airways as a consequence of poor intrauterine growth rather than superimposed airway injury or reactivity from neonatal respiratory disease (1;30). However, because small airways alone do not fully explain airway hyperreactivity, other mechanisms of small airway dysfunction are necessary to explain respiratory symptoms.

Several pulmonary outcome studies have reported significant increases (2-fold or more) in airway obstruction among VLBW infants without CLD following exposure to as little as 40% oxygen for 5 days (3;4;8;26). Not all studies have had similar results suggesting variability in effect or susceptibility of babies to oxygen exposure (31;32). In 1982, Coates et al. described increased small airway resistance at 10 year follow up of mildly

premature infants (mean gestational age 31 weeks and birth weight 2000 grams) treated with a high oxygen regimen and those exposed to a low oxygen regimen for the treatment of respiratory distress syndrome (RDS). Mechanical ventilation was not used in either group. Pulmonary function tests were performed on survivors receiving either the low or high supplemental oxygen regimen ten years after their initial illness. Infants treated with high levels of supplemental oxygen alone (no mechanical ventilation) had decrements in airway function similar to decrements in function reported for a historical cohort of RDS survivors treated with ventilation and high levels of supplemental oxygen. From these data, the authors concluded that neonatal exposure to high oxygen concentrations in the absence of mechanical ventilation is capable of causing long-term change in small airways (28). These studies suggest that use of lower supplemental oxygen concentration may improve respiratory health of infants who do not develop CLD.

Premature Infants Without CLD Have Increased Risk of Symptomatic Airway Dysfunction and Need for Outpatient Pulmonary Care.

For VLBW infants without CLD, the prevalence of parental or physician reported wheezing is increased compared with term infants, with estimates of the prevalence of wheezing ranging from 10-38% (4;8). Prevalence of wheezing requiring medications is greater compared with term infants. VLBW infants have a 2-4-fold increase in respiratory related re-hospitalization rates compared with term infants (4;8;33-35). Although most studies have found the risk of recurrent wheezing remains elevated throughout childhood, an Australian longitudinal follow-up cohort of VLBW infants found the prevalence of wheezing remained elevated for 2 years then returned to baseline (32;36).

Prevalence of Symptomatic Airway Dysfunction in Formerly Preterm Infants During the Surfactant Era Remains High

With the advent of surfactant therapy, survival of small infants increased dramatically and the incidence of CLD changed minimally (37-40). Classic BPD evolved into the "new CLD" characterized by reduced alveolarization and more variable airway changes (41). Pulmonary follow up studies during the surfactant era showed reduced pulmonary morbidity in surfactant treated patients. Typical of these studies, Sell et al. found the incidence of asthma was significantly lower in infants given synthetic surfactant compared with those given air placebo. Pelkonen et al. performed PFT measurements on 40 children aged 7-12 years who were born before 30 weeks of gestation with an immature surfactant system, and were randomized to one of three treatment groups: prophylactic surfactant, rescue surfactant and placebo (air). Spirometric parameters of children born preterm were compared with those of 20 children born at term. Bronchial obstruction was found in 53% of the prophylactically treated group, in 36% of the rescue group, in 67% of the placebo group, and in 0% of the control group (42). A recent report suggests that the introduction of surfactant therapy markedly altered the pulmonary outcome of premature infants. Published in 2001, the Newborn Lung Project Group reported results of a prospective 12-year follow-up of VLBW infants following the introduction of surfactant therapy (5;8;43). Among infants with CLD, wheezing symptoms decreased from 50 to 16% from the period before compared with the period after surfactant therapy became available. However, among infants without CLD the prevalence of wheezing increased from 14% to 38% with the introduction of surfactant. These data suggest that surfactant therapy has an effect on outpatient respiratory health and underscores the need to consider outpatient pulmonary outcomes in evaluating therapeutic strategies that potentially decrease surfactant replacement therapy.

CLD is an Incomplete Predictor of Outpatient Pulmonary Morbidity

Several authors have looked to respiratory symptoms and need for outpatient pulmonary care as outcome measures for neonatal lung disease (9;10;12;24). In 1988, from a retrospective chart review of 605 premature infants < 1500 grams, Shennan et al. found that the presence of BPD (oxygen requirement at 36 weeks PMA) had a 63% positive predictive value and a 90% negative predictive value for abnormal pulmonary outcome in the first 2 years of age. However, this study from before the era of exogenous surfactant therapy defined abnormal pulmonary outcome as death, oxygen requirement at 40 weeks PMA, 2 or more respiratory related hospital admissions, wheezing requiring drug therapy or persistent wheezing resulting in growth failure, handicap or hypotonia at 1 year of age. Such restrictive criteria for abnormal pulmonary outcome are likely to underestimate the burden of recurrent wheezing on former premature infants and their families. Several recent

interventional studies show that CLD is an incomplete predictor of clinical wheezing and need for outpatient pulmonary care and suggest that differences in oxygen exposure or oxidant stress may affect pulmonary outcome without affecting the incidence of CLD.

Interventional Trials That Did Not Reduce CLD But Did Reduce Outpatient Pulmonary Morbidity.

Recent data in preterm infants treated with human recombinant superoxide dismutase (SOD) found that anti-oxidant therapy did not reduce the incidence of CLD. However, among infants < 27 weeks gestation, SOD therapy resulted in significant reductions in the first year after NICU discharge in the number of emergency room visits and number of re-hospitalizations for respiratory problems and reductions in the need for bronchodilators suggesting a reduced prevalence of wheezing in patients treated with SOD (12). In a randomized, multi-center trial from Helsinki, N acetyl cysteine did not reduce the incidence of CLD. Outpatient pulmonary outcome of these patients has not been reported.

Treatment of Premature Infants With Higher Targeted Oxygen Saturations Is Associated with Poorer Pulmonary Outcome

In the STOP-ROP Study, infants exposed to higher levels of oxygen to achieve a targeted saturation of 96-99% compared with 89-94% had greater risk of adverse pulmonary events including pneumonia, chronic lung disease exacerbations and need for diuretics, oxygen and hospitalization at 3 months' corrected age. *Although all infants in this study had CLD at enrollment, different targeted oxygen saturations were associated with large differences in pulmonary morbidity.* Adverse pulmonary outcomes occurred with differences in FIO2 of as little as 10% for patients treated with ventilation, CPAP or hood (36% $\pm$ 14% vs. 46% $\pm$ 20%, respectively for low vs. high saturation range) and 5% for infants treated with nasal cannula, (26% $\pm$ 6% vs. 31% $\pm$ 11%, respectively for low vs. high saturation range) (44). In a similar study, The Benefits of Oxygen Saturation Targeting (BOOST) Trial randomized infants < 30 weeks' gestation to higher (95-98%) or lower (91-94%) saturations ranges beginning at 32 weeks' PMA to determine whether infants managed with higher targeted saturation range showed better growth and neurodevelopment. As in the STOP-ROP study, need for oxygen therapy was prolonged. Trends towards an increased risk of pulmonary death and fewer outpatient office visits (median 27.5 vs. 31.3, $p < .11$) were seen in the lower targeted oxygen saturation group (13).

Factors In Addition To Prematurity and Oxygen Contribute To Symptomatic Airway Dysfunction

Multiple factors in addition to prematurity and oxygen contribute to the development of airway dysfunction in children (Table 1). In the SUPPORT TRIAL Breathing Outcomes Study, these potential covariates will be measured and controlled for using a randomized trial design. These covariates will also be evaluated as independent predictors of pulmonary outcome in multivariate analyses.

Table 1. ***Important Covariates in Etiology of Recurrent Wheezing***

Demographcis – race, sex, ethnicity, parental factors (educational level, poverty status, and age), and family history of wheezing or atopy.

Environmental – daycare, siblings, crowding, tobacco smoke or wood smoke in the home, pets

Health Services – health care and respiratory medication use appropriate for level of respiratory symptoms

Medical- congenital anatomic airway abnormalities, neonatal sepsis, RSV and other viral infections

G. METHOD/ PROCEDURES

NICHD SUPPORT Trial Breathing Outcomes Study

G.1 Description of study design

This study will add an 18-22 month longitudinal, prospective follow-up study of surviving infants enrolled, randomized and treated as part of the multi-center NICHD Neonatal Research Network SUPPORT Trial.

G.2 Definition of study population

Infants with gestational age of $24^{0/7}$-$27^{6/7}$ weeks' gestation by best obstetrical estimate.

Inclusion criteria:

- Enrollment in the SUPPORT Trial
- Survival to hospital discharge
- Consent for enrollment into the Breathing Outcomes Study, obtained either at the time of enrollment into the SUPPORT Trial or separately.

Exclusion criteria

- Refusal of informed consent

G.3 Description of study intervention

Before delivery, infants will be randomized to subsequent management with high vs. low target oxygen saturation according to the SUPPORT Protocol. The SUPPORT Breathing Outcomes Study begins just prior to NICU discharge (Figure 1).

Figure 1.

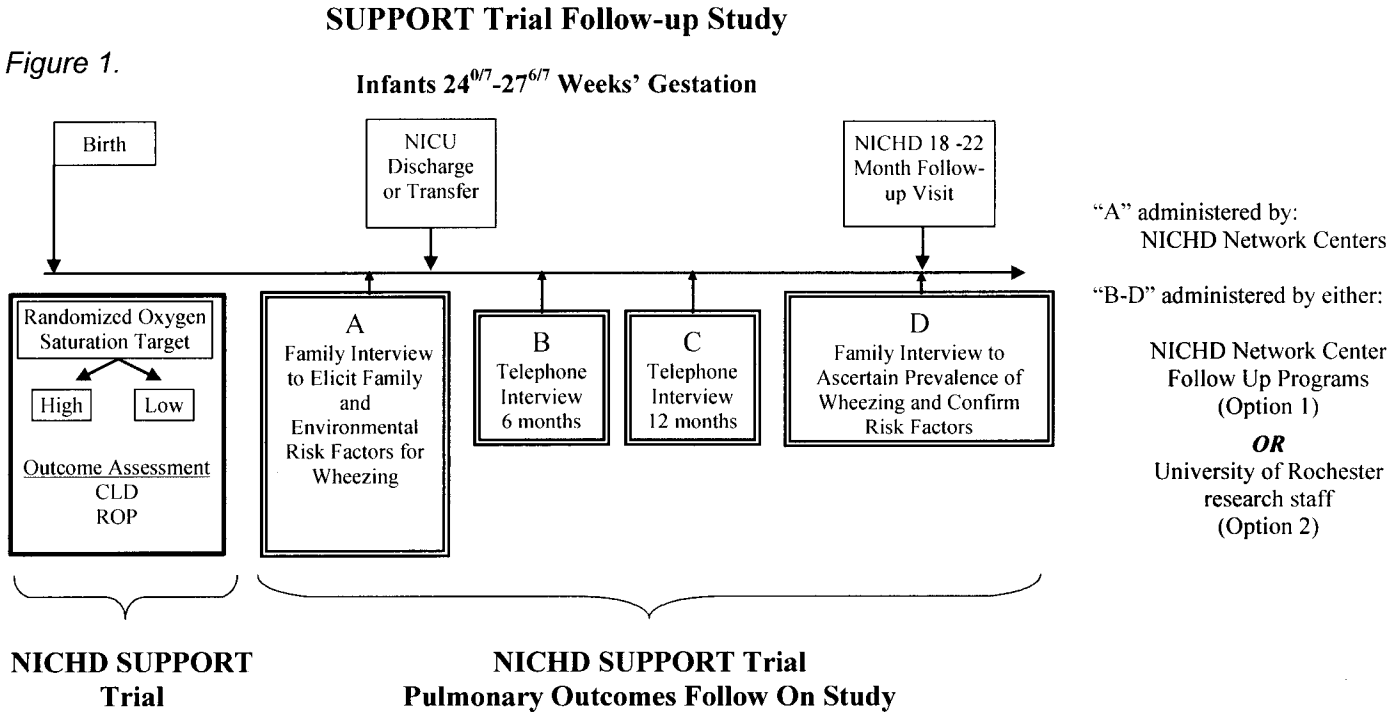

Fig 1, A. Parent (Guardian) Interview to Elicit Family and Environmental Risk Factors for Wheezing and Cough The family interview will be administered either face to face or by telephone to study

participants by site study staff prior to or within 30 days of NICU discharge. The questions are based on intake questions used by the Tucson Respiratory Study and are designed to elicit family history of asthma, atopy, and home environmental exposures and to identify likely care givers (NICU Discharge – Baseline Interview).

Fig 1, B. *Interview at 6 months PMA* – respiratory interval history

Fig 1, C. *Interview at 12 months PMA* – respiratory interval history

Interviews will be undertaken at 6 and 12 months to obtain an interval history of respiratory problems including wheezing, cough, medications used, and health services sought for respiratory related problems (6 and 12 Month Questionnaire). Interviews may be administered either by telephone or face to face.

Fig 1, D. *Parental Interview to Ascertain Incidence of Wheezing and Cough and Confirm Risk Factors*

This parent interview may also be administered either by telephone prior to the regularly scheduled 18-22 month NICHD developmental follow up clinic visit or face to face at the time of the visit. Contacting parents prior to the office visit will help improve the Developmental Follow Up Clinic attendance rate and will allow the clinic visit to provide a back up means to contact the family. The 6, 12 and 18-22 month interviews will be conducted either by the local NICHD Follow Up Program (Option 1) or long distance from Rochester (Option 2), based on center preference (see table 2 below). The interview questionnaires are based on questionnaires administered by the Tucson Respiratory Study at approximately one year of age (18-22 Month Questionnaire). Questions are designed to ascertain the frequency and severity of wheezing and cough episodes and to assess need for outpatient pulmonary care. In addition, risk factors obtained at the 1st interview will be confirmed.

Each interview will collect a 6 month interval history, which, when taken together, will provide a complete respiratory history over the first 18-22 months' corrected age. If one questionnaire is not completed, the subsequent questionnaire will include the full interval history since the last completed questionnaire.

To standardize administration of the interview, the Rochester site will lead an interviewer training program consisting of two parts. Part 1 will consist of a teleconference to discuss study questions and interview script in question by question detail. Part 2 will consist of a practice interview in which interviewers from each center interview the Rochester trainer, who simulates a standardized patient. Following the practice interview, the Rochester trainer and practice interviewer will discuss the interview and give feedback. All interviewers will be required to complete this training.

G.4 Precise definition of co primary/secondary outcomes

G.4.1 Definition of primary outcomes- parental report of recurrent wheezing and chronic cough.

Two primary outcomes will be measured, the incidence of recurrent wheezing and incidence of chronic cough. Whether individual symptoms (recurrent wheezing or chronic cough, alone) or a combination of these symptoms (wheezing and/or chronic cough, together) best quantifies symptomatic airway dysfunction following premature birth is controversial. Many studies have used wheezing alone as a primary outcome measuring pulmonary morbidity in formerly premature infants (10;12;14;48). In 1996, Greenough, using a combined outcome of either wheezing or chronic cough as a measure of symptomatic airway dysfunction, found that greater pulmonary symptoms were associated with longer durations of supplemental oxygen and mechanical ventilation (49;50). Later, in a follow-up study of infants enrolled in The United Kingdom Oscillator Study (UKOS), Greenough found that frequent wheezing episodes but not chronic cough were associated with neonatal respiratory events (51;52). In our study, to address this issue most conservatively, recurrent wheezing and chronic cough will be measured as co-primary outcomes. Secondary analyses will consider these outcomes in combination.

The incidence of wheezing will be ascertained using the primary question used and validated in the Tucson Children's Respiratory Study (a large prospective birth cohort study of term infants) (53-59), "Has his/her chest ever sounded wheezy or whistling?" (53). Likewise, the incidence of cough will be ascertained using the Tucson question, "Has this child ever had a cough when he/she did not have a cold?" (53). As in Greenough's study, recurrent wheezing will be defined as episodes of wheezing occurring more than twice/week. Chronic cough will be defined similarly, cough occurring as more than twice/week. Additional questions will further characterize the wheezing and coughing episodes, including whether symptoms were associated with a viral illness (parental report of a "cold") or an environmental exposure. A symptom diary will be offered to study participants to help facilitate recall of pulmonary symptoms and need for outpatient pulmonary care.

The Tucson Children's Respiratory Study administered the questionnaires both in person and by phone, depending on patient availability. The investigators did not undertake a formal validation of phone vs. face-to-face administration of the questionnaire. Anecdotally, based on phone conversation with the study coordinator, investigators did not observe a difference in quality of responses between phone and questionnaires administered in person.

G.4.1.1 Standard Definition of Wheezing

Several studies have found that multiple colloquialisms in both English and Spanish can be used to describe wheezing (60-64), creating opportunity for misinterpretation of respiratory sounds and potential for over or under estimation of the incidence of wheezing. Other studies have found that clips of respiratory sounds played for families improve accuracy of symptom reporting (65;66), providing data relatively free from biases due to language, culture, literacy or interviewing techniques. To minimize misinterpretation of other respiratory sounds as wheezing, we will provide a verbal AND a brief audio clip that can be played for the interviewee at the beginning of the interview (electronic clip included separately). Accompanying the audio clip, wheezing will be defined verbally by the interviewer as an expiratory sound (a sound that is made when breathing out, not in) coming from the chest, sometimes described as whistling or musical. Although not yet widely used, use of audio clips to standard symptom definition is the best approach to bridge the language gap that exists between English and Spanish and among Spanish speaking populations using different dialects or colloquialisms.

In administering the questionnaires, every effort will be made to accurately measure the occurrence of pulmonary symptoms and health care and medication use, thus establishing the true incidence of pulmonary morbidity in the study population as a whole. Most importantly, however, because pulmonary morbidity is a blinded outcome of a randomized controlled trial, bias favoring one study arm over another should not occur.

G.4.1.2 Parental Report for Non-English Speaking Populations

Upon finalization of the questionnaires, Spanish language versions will be created and made available to all centers. The Cornell Translation Service, a University based professional translation service, will be contracted to perform the translation. For centers choosing to administer the questionnaires locally (Option 1), each center will be free to choose their primary interviewer who has the necessary skills. Administration of the questionnaire by a native speaker of the local Spanish dialect is recommended. For centers choosing Rochester to administer the questionnaire to their patients (Option 2), English and Spanish speaking individuals, trained to administer the questionnaires, will conduct the telephone or face to face interviews. An audio clip and verbal definition of wheezing will be presented to the respondent to standardize interpretation of wheezing and to minimize ascertainment biases due to language, culture, literacy or interviewing techniques.

G.4.1.3 Parental Report of Pulmonary Symptoms Is a Reliable Outcome Measure of Airway Dysfunction

Evaluation of frequency and severity of respiratory symptoms by parental questionnaire and need for pulmonary care has been used as the primary outcome in multiple follow up studies of term and premature infants (10;12;14;48). A recent review evaluated the value of respiratory symptom history ascertained by parental questionnaire in determining the risk for developing asthma in early childhood. By evaluating 9 large, longitudinal, full term birth cohort studies and reviewing the original questionnaire from 7 of these studies, Koopman found that the questions posed to parents eliciting a history of wheezing in their infants were similar. Parental report of wheezing predicted an increased risk for later respiratory symptoms, including asthma. In the studies proposed here, incidence of recurrent wheezing and chronic cough ascertained by parental report will be primary outcomes, rather than physiologic measurements of airway dysfunction, for several reasons.

G.4.1.4 Reasons to Use Parental Report of Recurrent Wheezing and Chronic Cough as Primary Outcomes

- Parental interview can be performed more readily on large numbers of patients. The validity of this approach has been shown in several longitudinal studies including The Tucson Respiratory Study.
- Recurrent wheezing is highly correlated with changes on pulmonary function testing (PFT). In infants with CLD, a history of wheezing was associated with greater expiratory flow limitation, hyperinflation and airway responsiveness to albuterol on PFT compared to those without such a history (24).
- Parental recall of respiratory illnesses has been shown to correlate strongly with review of medical office records. For asthma and bronchitis in the past year, Pless et al. found good agreement between recall of 288 parents and physician office chart review. Parental education and occupation were not predictive of a parent's ability to recall the illness (67). In an assessment of parental recall done to evaluate minor injury in children, Harel found recall declined with time, with the best recall occurring in the first 3 months after injury with further decline after 6 months from the time of the injury (47;68;69).
- Symptomatic airway dysfunction can be assessed in a standardized way. The NHLBI Consensus Expert Report developed standardized questions to assess severity of airway dysfunction. Three standardized questions from this report will be administered at 6, 12 and 18 months to assess symptom severity (70).

G.4.2 Definition Of Secondary Outcomes - Physician Diagnosed Wheezing. A secondary outcome will be parental report of physician diagnosed wheezing, defined as an episode of wheezing occurring at a health care visit. Physician diagnosed wheezing will be collected by parental report during the telephone or face to face interviews, using the question "Has your child been diagnosed with wheezing by a doctor?"

G.4.3 Definitions of Secondary Outcomes - Measures Need and Volume of Outpatient Pulmonary Care
Important secondary outcomes of outpatient pulmonary morbidity will be collected (Table 3).

Table 3. *Secondary Outcomes, Covariates and Sources*	
Outcomes	**Source**
Secondary Outcomes	
Number and duration of outpatient pulmonary medications including bronchodilator, diuretic, methylxanthine, and inhaled and systemic steroid therapy.	Family interview
Number of office visits for respiratory illnesses including pneumonia, bronchiolitis, asthma, bronchitis	Family interview
Number of emergency room visits for respiratory illnesses including pneumonia, bronchiolitis, asthma, bronchitis	Family interview
Number of re-hospitalizations for respiratory illnesses including pneumonia, bronchiolitis, asthma, bronchitis	Family interview
Growth at 18 months PMA (height, weight and head circumference)	NICHD follow up clinic data

G.4.4 Data Collection

Data collection for The Breathing Outcomes Study will be accomplished using one of two options (Figure 2, Table 2). Regardless of Option chosen, each local center will be responsible for obtaining informed consent and tracking patients following discharge.

Consent: For both options, every effort will be taken to enroll ALL SUPPORT patients into the Breathing Outcomes Study, including currently enrolled SUPPORT patients (both patients still in NICU and those discharged) and future enrollees. By obtaining pulmonary outcome data for both current and future SUPPORT patients, death or adverse pulmonary outcome can be analyzed as competing outcomes. Sample consent forms for currently enrolled and future SUPPORT patients are attached.

G.4.4.1 Data Collection: Ascertainment of Outcomes - Field Work

A. Ascertainment of Wheezing and Outpatient Pulmonary Morbidity By Interview.

There will be 4 parental interviews over 18-22 months, one face to face interview or telephone prior to or within 30 days of NICU discharge and 3 subsequent interviews (by telephone or face to face) at 6 month intervals to collect data on recurrent wheezing, chronic cough and volume of outpatient pulmonary care (Figure 1, A-D above). Based on review of longitudinal studies of full term infants in which follow up patient contacts occurred quarterly to once every 18 months', a 6 month interval for follow up patient contacts is planned in an effort to reduce parental recall omissions which are more likely to occur with less frequent follow up (48;68). The 4 interviews are designed to collect the primary and secondary outcomes of the follow-up study. Other inpatient and outpatient data will be collected as part of the NICHD Neonatal Network Generic Database (GDB) and Follow-up Program.

B. Interview Instruments – Questionnaires are based on the Tucson Children's Respiratory Study, a longitudinal cohort study that followed healthy term infants from birth to over 20 years of age. Questionnaires have been updated with validated symptom severity and tobacco smoke exposure questions, a current list of available respiratory medications and modifications that address health issues faced by formerly premature infants such as use of palivizumab for RSV prophylaxis. The original Tucson questionnaires are designed to elicit a thorough history of possible covariates, such as environmental and infectious exposures and family histories of atopy, asthma or respiratory disease.

C. Administration of Interview Instruments – Six, 12 and 18-22 month interviews will be initiated in one of two ways (table 2):

C.1 Option 1 - NICHD Network Center Follow Up Programs (local contact)

Individual NICHD Network Centers may choose to undertake administration and tracking of patients enrolled in the SUPPORT Breathing Outcomes Study. Local administration of the questionnaires capitalizes on existing NICHD resources available at local centers. Each Network Center choosing local administration of the telephone or face to face questionnaire will identify one or more interviewers who will undergo training in the administration of the questionnaire and tracking of enrolled patients. The Rochester Health Service Research Group will provide training and server as a resource to answer questions regarding administration of the questionnaire (outlined above).

Advantages of Conducting Telephone Interviews From the Local Network Centers

Conducting the telephone interviews from Local Centers will:

1) reduce risk for HIPPA violation
2) capitalize on existing rapport between the patient's family and their local center
3) avoid redundancy in making tracking calls to families

C.2 Option 2 - University of Rochester research staff (long distance contact)

The University of Rochester Neonatology Research Group has conducted similar telephone interview designs as part of an ophthalmologic outcome study of patients enrolled in a randomized trial of cryotherapy to treat ROP and a 15-year, longitudinal neurological assessment conducted by telephone survey among 132 infants treated with surfactant. Telephone follow up rates were 96% follow up at 7 years and 95% follow up at 15 years (71). In the study proposed here, the University of Rochester Health Services Research Group (HSR Group), will conduct the telephone interviews.

In telephone follow up surveys conducted by the HSR Group, follow up rates at 12 months' have exceed 75% in populations at high risk for being lost to follow up (72-78). Working with NICHD Network Centers to assist in tracking local families, follow up rates for this Follow-up Study are expected to exceed 80% and should approach the average annual NICHD follow up rate of 83%.

To facilitate tracking and record keeping, Network Centers choosing Rochester to administer questionnaires to their patients (table 2) will provide contract information to the Rochester site. RTI International will provide monthly updates of patients due for interviews. Local centers will be responsible to maintain updated contact information. Each interview will close with a question as to whether the family plans a new address or phone number prior to the next interview. The names and phone number of a friend or relative will be sought so that they may be contacted in the event that contact with the patient is lost. If contact information is updated, the new contact information will be transmitted back to the local center. By interviewing families every 6 months, a higher follow up rate will be achieved because family contact information will not become so out of date that the family is lost or that re-contacting them is inefficient. We anticipate that each interview will require 2 hours of staff time, with 20-30 minutes to conduct the interview and 90 minutes to contact family and enter data.

Advantages of Conducting Telephone Interviews From a Central Research Facility

Conducting the telephone interviews from Rochester will:

1) require less effort from the individual Network Centers
2) allow standardization of the telephone interview by a core group of trained interviewers
3) blind the telephone interviewer to the SUPPORT Trial study group designation
4) reduce the cost of the study by consolidating the telephone training and follow up at one site.

G.4.4.2 Data Collection: Ascertainment of Environmental and Genetic Covariates

Ascertainment of important environmental exposures and genetic risk factors that might confound the relationship between supplemental oxygen exposure and symptomatic airway dysfunction will be obtained along with the primary outcomes during the same interviews (Table 4). Tobacco smoke exposure is a potentially significant risk factor for airway dysfunction. The tobacco smoke question in the Tucson Study has been replaced by a question shown by Dr. Wakefield et al to correlate with cotinine levels in infants (79;80).

Table 4. Postnatal and Genetic Covariates Evaluated as Potential Confounders of Oxygen and Wheezing

Covariates in Home Environment and Exposures The initial questionnaire and 6 month interviews will gather information on other *inhaled exposures* (tobacco, wood stoves, cold air), *residence* (crowding, siblings, daycare), *infectious exposures* (RSV, palivizumab) and medical risk factors (congenital anatomic airway abnormalities)

Covariates in Family History Questionnaires will elicit *family history* of atopy (family history of asthma, eczema or allergy to foods, pets).

G.4.4.3 Data Collection: Ascertainment of Primary Exposure

Oxygen Exposure

In the SUPPORT Trial, it is assumed that managing infants with a higher vs. lower targeted oxygen saturation range will result in different levels of supplemental oxygen exposure. The SUPPORT Trial will collect data on FIO2 exposure to quantify the anticipated difference. As part of the SUPPORT Trial, FIO2 values will be recorded and analyzed at many time points including time of admission, first blood gas, and as described in the SUPPORT Manual of Operations, Chapter 10 Safety Monitoring Form. Because oxygen is the primary exposure in the SUPPORT Breathing Oucomes Study and plays a central role in the disease model proposed, oxygen exposure will be quantified as described in the main SUPPORT trial and analyzed as a predictor of later symptomatic airway dysfunction.

G.5 Sample size estimate with some statistical support based upon primary outcome

G.5.1 Sample Size

The SUPPORT Trial anticipates enrollment of 1310 patients $\geq 24^{0/7}$ and $\leq 27^{6/7}$ weeks' gestation, providing 80% power to detect a 10% difference between treatment groups in the incidence of death/CLD and death/stage III Retinopathy of Prematurity (ROP). Assuming mortality of 22% for infants in this GA range (NICHD 2001-2002 data), 1021 infants would be expected to survive and be eligible for the SUPPORT Breathing Outcomes study.

Power for detecting a difference between the high vs. low saturation groups for the primary outcome

First we consider power for detecting a difference between the high and low saturation groups for the first primary outcome, recurrent wheezing. We expect the incidence of wheezing to be about 0.17 in the low saturation group and about 0.31 in the high saturation group (12). For the power calculations, we also consider a scenario with a smaller difference between groups: 0.19 for the low saturation group and 0.29 for the high saturation group. We expect the follow up rate to be about 80% (NICHD historical average follow up rate), which would result in data on about 816 patients. We also consider a lower follow up rate of 65%, which would result in about 663 patients. Power to detect a difference between groups based on a chi-square test with type I error alpha set at 0.05 is given in Table 5 for each scenario. From those results, we expect to have more than 80% power for the primary outcome. Also of interest are subgroup analyses, where we look separately at the CLD and non-CLD subjects. Of survivors, we expect 37% or 378 infants to have CLD. For the CLD group, we expect the incidence of wheezing to be about 0.5 in the high saturation group and 0.3 in the low saturation group. If there is a 80% follow up rate, we will have 95% power to detect a difference between the two groups. For the non-CLD subgroup, we expect the incidence to be 0.2 and 0.1 in the high and low groups, respectively. With 80% follow up, we will have 92% power. Thus, we expect to have adequate power for the primary outcome even in the analyses stratified by CLD.

Table 5. Power for primary outcome.

Follow-up rate	Low Saturation	High Saturation	power
80%	0.17	0.31	0.99
80%	0.19	0.29	0.90
65%	0.17	0.31	0.98
65%	0.19	0.29	0.83

Power for detecting a difference between the high vs. low saturation groups for secondary outcomes

We expect the study to be adequately powered for analysis of important secondary outcomes such as use of pulmonary medications. Based on results reported in Davis et al. for infants less than 27 weeks' gestational age [22], we expect the rate of pulmonary medication use to be 0.42 in the high saturation group and 0.19 in the lower saturation group. In that case, even with a 65% follow up rate, we would have more than 99% power to detect a difference between the groups with a chi-square test. Similarly, the CLD subgroup analyses would have more than 80% power under those assumptions. Based on the power numbers above, we could potentially enroll fewer subjects in the trial and still have adequate power. However, we choose to over enroll slightly to make up for the fact that some patients will likely be lost to follow up. The recruitment time will be that of the SUPPORT Trial (2 years) with a run out period of 18-22 months to ascertain follow-up outcomes. The total study period is 36-40 months.

G.5.2 Data Analysis

Analysis of primary dichotomous outcomes will be performed by chi square test and presented as a relative risk for development of that outcome. Number of outpatient pulmonary visits for respiratory illnesses will be presented as median values. The Wilcoxon Rank Sum test, a non-parametric alternative to the two-sample t-test, will be used to test for differences between the two groups. Statistical analyses will need to consider the effect of multiple comparison groups on the level of statistical significance. All analyses will be performed in conjunction with the Research Triangle Institute (RTI, North Carolina). Data will be presented as shown in tables 6-7. Mean FIO2 values in the high and low SpO2 groups will be compared by two sample t-test. Analyses will be done to evaluate the effect of ventilator strategy on pulmonary outcome and presented similarly to table 6 and 7. Other secondary analyses will be performed, including analyses of respiratory outcomes by presence or absence of CLD (oxygen at 36 weeks' PMA determined by SUPPORT study criteria). The incidence of outpatient respiratory diagnoses, such as asthma or reactive airway disease, will be compared between intervention groups and, in sub group analyses, between intervention groups by presence or absence of CLD.

Table 6. *Primary Dichotomous Outcomes*	**Low Saturation**	**High Saturation**	**RR**	**CI**	**p-value**
Parental Report of Recurrent Wheezing (%)					
Parental Report of Chronic Cough (%)					
Need for Outpatient Pulmonary Medications (%)					
Need for Physician Visit for Respiratory Illness (%)					
Need for Re-hospitalization for Respiratory Illness (%)					

Table 7. *Primary Outcomes – Continuous Outcomes*	**Low Saturation**	**High Saturation**	**p-value**
Number of Physician Visit for Respiratory Illness (Median)			
Number of Emergency Visits for Respiratory Illness (Median)			
Number of Re-hospitalization for Respiratory Illness (Median)			

G.5.2 Expected Results

We predict that premature infants managed with a lower targeted oxygen saturation range compared to those managed with a higher targeted oxygen saturation are exposed to lower levels of supplemental oxygen and have reduced risk of recurrent wheezing in the first 18-22 months' CA.

G.5.2 Anticipated Problems and Solutions

1) Participant attrition. As seen in the sample size calculation, the potential for patients to be lost to follow up over time will be offset by over enrolling patients to participate in the follow up. Because patients who enroll in the SUPPORT Trial are randomized, there should be no systematic bias favoring one group over another among patients who are lost to follow up. However, if loss to follow up is in part caused by the treatment or outcomes, this could bias the results. We will therefore investigate whether there are differences in key variables for subjects who are lost to follow up compared to those who remain in the study. For example, we will test whether subjects in one treatment arm were more likely to be lost to follow up than in the other arm. Similarly, we will compare wheezing rates at 6 months' for those who are later lost to follow up compared to those who remain in the study. We do not expect to see any major differences.

2) Difficulty tracking families. With mobile families, keeping contact information up to date may be difficult. To promote successful follow up in both the Breathing Outcome Study described here and the routine NICHD neurodevelopmental follow up visit at 18 - 22 months, each center will be responsible to track families to maintain current contact information for both the family and primary care physician.

3) Center variability in administering the questionnaire. With 11 centers administering the questionnaires, variation in techniques and styles in administering the questionnaires has the potential to introduce ascertainment bias. To minimize this risk, staff administering the questionnaires will undergo an interviewer training program conducted by the Rochester Site. The program will consist of a conference call and a practice interview of a standardized patient.

4) The SUPPORT Breathing Outcomes Study has been prepared as the central project for Dr. Stevens' Patient Oriented Clinical Research Grant (K23 Award), revised submission 7/1/05. If approved, funds from the K23 will be available to offset a portion of the cost of conducting this Follow-up Study. If not approved, NICHD funding has been approved to support the project.

5) Initiation of the Breathing Outcomes Study after enrollment into SUPPORT has begun.

5.1 Babies already enrolled in SUPPORT

To help assure pulmonary outcome assessment for all SUPPORT patients, families of babies already enrolled in SUPPORT will be approached with a separate consent to enroll in the Breathing Outcomes Study. IRB approval of this consent form will be required.

5.2 *Future babies eligible for enrollment in SUPPORT*

Going forward, a modified SUPPORT Consent Form, which includes consent for the Breathing Outcomes Study, will be need to be prepared at each center. The revised SUPPORT Consent will require enrollment into both the SUPPORT Trial and the Breathing Outcomes Study prior to delivery. Because a significant amount of time may elapse between enrollment and the first interview, the Breathing Brochure will be discussed with families, either prior to NICU discharge or within 30 days after NICU discharge.

G.6 Available population/compatibility with other ongoing protocols

Another secondary study proposed by a group independent from ours is looking at the genetics of reactive airways disease in patients enrolled in the SUPPORT Trial. The follow on study proposed here should be complementary to the genetics study, enhancing the both the quality and quantity of data on the prevalence of wheezing and need for outpatient pulmonary care in patients enrolled in the SUPPORT Trial.

G.7 Estimate of projected recruitment time

The recruitment time will be that of the SUPPORT Trial with a 18-22 month period of follow up to ascertain primary and secondary outcomes.

H. RISKS / BENEFITS, WITH ESTIMATE OF FREQUENCY / SEVERITY OF RISKS.

By using clinical measures of outpatient pulmonary morbidity, the effect of NICU based respiratory interventions on respiratory health and need for outpatient medical care may be quantified, allowing assessment of whether infants who develop CLD and those who do not have improved pulmonary health as a result of the study intervention. In addition to creating a potential model for outpatient pulmonary follow up, the proposed follow on study may improve follow up at the 18-22 month NICHD visit by maintaining contact with families during the interval between NICU discharge and the follow up visit. We anticipate no risk to the patient of this observational follow on study.

Subject: Comments for SUPPORT Breathing Outcomes - Follow Up Coordinators Call 11/17
Date: Thursday, November 17, 2005 10:12:24 AM

Dear Participants of today's call,
Please see the email messages below for comments concerning the timing of questionnaire administration and other issues for the Breathing Outcomes Study.

Agenda
Thursday, November 17

2:00-3:00pm Breathing Outcomes
3:00-4:00pm Inositol Cross Sectional Study (Indiana, Yale, Brown, Stanford, Duke, Wake Forest, Rochester)

Dial toll free: **1-888-**[redacted]
Passcode: [redacted]*(then press #)

Thanks, Jamie

Jamie E. Newman, MPH

Subject: Fwd: Re: SUPPORT Breathing Outcomes - FU Coordinator Call11/17

Jamie, just wanted to be sure you got the e-mail below and had a chance to forward it to the others.

Also wanted to bring up one other issue regarding timing of the 6 and 12 month interviews. According to the manual, these are to be performed at 6 and 12 months corrected age +/- 2-4 weeks. Since all of these infants will be at least 12 weeks (and as much as 16 weeks premature) the interviews would occur around 9-10 months and 15-16 months chronological age, respectively. These ages could coincide with ages sites would otherwise see these children for clinical reasons, though perhaps not as likely as for 6 and 12 months chronological age. In any case, for those sites planning to do these interviews face-to-face, it is important they realize that the study is not budgeted to cover the cost of research visits. So if they cannot take advantage of clinical visit dates, they will need to default to phone interviews.

>>> Roy Heyne 11/15/05 5:04 PM >>>
Jamie, one other question came up with regards to the 18-22 month follow-up, which is actually a component of the primary study , though the Breathing Outcomes secondary adds a questionnaire to it. Granted most of the infants in SUPPORT will be <1000 grams B.W.; but a small percent may be bigger, in

which case they would not be eligible for generic network follow-up. Even if they are eligible, they would need to be separately enrolled in the generic follow-up, in order to qualify for the incentive that we pay for bringing the child back at that time. However, if they are not eligible, it does not appear that either the primary or the secondary offer any incentive for them to return for the 18-22 mo study exam, which might lead to some "selection" bias in follow-up. Furthremore, I think it remains to be seen what sustained level of cooperation we will have with repeated 15-20 minute interviews over the course of 18 months with no incentive beyond good-faith cooperation.

Could you broadcast this to the others who will be participating in the call Thursday, since I think it is something we need to discuss. Thanks.

>>> Roy Heyne 11/14/05 8:16 AM >>>
Thanks for incorporating all the changes we discussed last month. There are a couple of other minor changes I would recommend, and a couple of more significant ones.

1) In Q. 13 on the 6,12,18 month interviews, you might want to add a parenthetical augmentation to "BPD" to cover the alternate description of that disease: "...BPD (or Chronic Lung Disease of Prematurity)..."

2) On 2-5 of the manual, in the revised paragraph about the brochure, would be good to insert language to cover discussion of brochure in the follow-up clinic, for situations where that needs to be an alternative: "...as they leave the NICU or at a follow-up clinic visit..."

3) For questions 9e-g, I had previously raised a question about the gap between "Never" and "Twice a week". While I agree we don't necessarily need to insert an intermediate frequency, I do think you need to broaden the "Never" to "Never or less than twice a week" so we will have some category that fits "once a week" or some other frequency less than 2/wk. (You have done something similar in question 12).

4) On the sample consent, C-2, the last paragraph before "Number of Participants" needs to be omitted, since we have decided to forego the physician chart audit.

Subject: RE: Support question

Hi Rose
This is only an issue for infants still on oxygen. In the course of providing care to any enrolled infant the more frequent scenario is removing an infant from his/her oximeter and then the infant in most units will be placed back on a conventional oximeter. There is so much random noise and differences between any 2 oximeters, that I do not believe that this is an issue. Thus the risk for unblinding is more frequent with the discontinuation of the study oximeter. I am unaware as to whether this has been an issue.
I would recommend that the study oximeter be removed and replaced by an individual who will not do the physiologic challenge, and not by the coordinator, and that an interval of at least 2-4 hours be allowed before the physiologic challenge is performed. There is no urgency to do the physiologic challenge and I believe that an interval of at least 2 -4 hours will be adequate to remove any potential unblinding.
I can be available for a call on Wednesday preferably early my time , between 7:00 and 9:00 AM - your time before 12:00 Noon, and Friday before 12:00 Noon my time. I am in LA Thursday for a CPQCC meeting. However if this day works for the others I would try to be available ideally between 7:30 AM and 9:30 AM.
Let me know
Neil

Subject: Support question

Hi
At the gdb retreat the issue of potential unblinding of oximeters has been raised. If the physiologic challenge is done exactly at 36 weeks and the child's oximeter is changed on that day with a resultant shift up or down in sat levels, the coordinators are concerned that unblinding for that infant and possibly the trial may occur (if the color of the oximeter was known to the staff). We need to have a call this week to discuss this.
Send carolyn your availability for a call this week for
Nov 16
Nov 17
Nov 18

Thanks
Rose

Subject:	Reminder: SUPPORT Breathing Outcomes - Follow Up Coordinators Call 11/17
Date:	Tuesday, November 15, 2005 3:11:23 PM

Dear Follow-up Coordinators,

The Breathing Outcomes study documents will be discussed on Thursday November 17 from 2-3pm.
The Breathing Brochure was distributed on 11/10 and the Forms, Manual, and Protocol were distributed on 11/3. We anticipate this being the last round of revisions so if you are unable to join the call, please submit your comments by email.

We ask that all Follow Up coordinators join the Breathing Outcomes portion and for Inositol, just the sites participating in the Cross Sectional study. However, all are welcome to join.

Agenda
Thursday, November 17

2:00-3:00pm Breathing Outcomes
3:00-4:00pm Inositol Cross Sectional Study (Indiana, Yale, Brown, Stanford, Duke, Wake Forest, Rochester)

Dial toll free: **1-888-994**(b) (6)

Dear Follow-up Coordinators,

Attached are the SUPPORT Trial Breathing Outcomes Study documents revised after the call on Tuesday November 1. Due to the confusion with the SUPPORT Follow-up Study and due to IRB concerns with long study titles with multi-syllable words, the title of this study has been changed to the "Breathing Outcomes Study" . We would like to have a call with the coordinators to hear your comments on the Manual and Forms. Several of you have Thursday, November 17 at 2pm already blocked off for the routine NRN Coordinators call. Please let me know if you will be able to join the call from 2-3pm so that we can have a head count of who to expect.

The breathing brochure (formerly the breathing diary) will be distributed to you next week. Please let me know if you have any questions.

Thanks, Jamie

Post-natal Growth of Infants Enrolled in the NICHD Neonatal Network Oxygen Saturation (SUPPORT) Study: A Proposed Secondary Study

Cristina Navarrete MD, and Shahnaz Duara MD
University of Miami Miller School of Medicine, Miami, FL.

Abstract:

Post-natal growth restriction is a major problem in preterm infants. Perturbations in oxygenation are recognized to influence post-natal growth; hypoxic conditions can directly impair growth and hyperoxic conditions predispose infants to BPD, which in turn has been linked to poor growth. The NICHD Neonatal Network is conducting a prospective trial of preterm infants randomized to two levels of baseline oxygen saturations. The effect of baseline saturations on pulmonary morbidity and ROP are the primary outcome measures. With respect to post-natal growth, there is a paucity of data relating alterations in baseline oxygen saturation and/or frequent deviations above or below the baseline to growth outcomes. We propose a secondary study to quantify short-term growth velocity in-hospital and long-term growth at 18-22 months of corrected age for infants enrolled in the SUPPORT Trial in relationship to oxygen saturation.

A. Hypothesis to be tested

Primary:

1. Infants in the low oxygen saturation group (85-89%) will have better in-hospital and long-term (18-22 months corrected age) growth.

2. Trajectories of growth in hospital will be better for infants in the low oxygen saturation group.

Secondary:

1. Growth will be greater in infants who spend > 50% of the time with daily median oxygen saturation between 85% -95% while on supplemental oxygen, independent of randomization to low or high oxygen saturation.

2. Infants with BPD will have poorer in-hospital and long-term growth than infants without BPD, independent of the saturation randomization arm.

3. Better long-term growth will be positively related to neuro-developmental outcome, independent of the saturation randomization arm.

B. Specific Aims:

1. To determine anthropometric measurements (wt, HC, length) in infants randomized to low and high oxygen saturation arms, from birth to hospital discharge and again at 18-22 months corrected age.
2. To determine nutritional intake (parenteral and enteral) during hospital stay.
3. To determine the percentage of infants with growth <10 percentile at 36 weeks PMA or discharge, whichever comes first.
4. To determine the percentage of infants with growth <10 percentile at 18-22 months corrected age.
5. To determine growth in relation to the proportion of time spent with oxygen saturation
    a. <85% and >95%
    b. 85%-95%
6. To determine growth in relation to infants' median oxygen saturation while in supplemental oxygen
    a. median oxygen saturation > 95%
    b. median oxygen saturation 85% - 95%
    c. median oxygen saturation < 85%
7. To relate incidence of BPD in low and high saturation arms to growth.
8. To determine in-hospital growth velocity/trajectory in low and high saturation arms.
9. To determine long-term growth velocity/trajectory, from hospital discharge to follow up at 18-22 months corrected age in low and high saturation arms.
10. To relate neuro-developmental outcome at 18-22 months corrected age to long-term growth in low and high saturation arms.

Rationale:

The SUPPORT Trial will randomize infants to two ranges of SpO2 in order to test the hypothesis that use of a lower SpO2 range will result in an increase in survival of preterm infants without the occurrence of threshold retinopathy of prematurity and/or the need for surgical intervention. Retrospective cohort data from several units in the U.K., with different oxygen supplementation policies, revealed poorer growth patterns in the preterm infants exposed to higher oxygen saturations for the duration of oxygen exposure (Tin 2001). Conversely, observational data of infants with established BPD show better growth with home oxygen support (Groothius 1987), and two recent RCT of different target saturations in older oxygen-dependent premature infants showed no difference in short or long-term growth outcomes (STOP-ROP 2000, BOOST Trial 2003). There are no RCT data evaluating the short or long-term growth impact of different SpO2 strategies with supplemental oxygen use in a birth cohort of extremely preterm infants. Therefore, this study provides an opportunity for us to

obtain critically needed growth information on premature infants who are exposed from birth to different target oxygen saturation strategies.

Background

Improvements in antenatal care, respiratory support and nutrition have contributed to increased survival of ELBW infants. As the number of survivors increase, the long term outcome of these infants becomes more important. Lemons et al described growth failure or weight <10th percentile at 36 weeks postmenstrual age in 97% of ELBW infants surviving to discharge. Some morbidities in adulthood are linked to growth during the early post-natal period (Singhal 2004) and make adequacy of growth in this population of heightened interest.

Instead of following intra-uterine growth curves of age matched fetuses, VLBW infants exhibit wide-spread post-natal growth retardation (Cooke 2004), losing ground during the first weeks of life (Berry 1997). To resume growth post-natally, nutrition is of paramount importance; however, other factors such as severity of illness and perhaps oxygenation also play a role. Observational studies of infants with BPD showed poor post-natal growth when infants were sent home without oxygen supplementation (Markestad 1981).

Although preterm infants without lung disease attain oxygen saturations >95%, artificial attempts to keep arterial oxygenation at a "physiological" level may not be beneficial to growth, the lung or retina (Tin 2001). Animal studies have shown that newborn mammals (mice, rats, guinea pigs) develop poor growth with chronic hypoxia and that blunted body growth is directly proportional to the profundity of the exposure to chronic hypoxia (Mortola 1990). Chronic hypoxemia has also been suggested as the cause of poor growth in patients with cyanotic congenital heart disease (Dundar 2000). When home oxygen supplementation was discontinued inappropriately by parents in a cohort of VLBW infants with BPD, there was a deceleration in the rate of weight gain, which improved when oxygen supplementation was resumed (Groothius 1987). Hudak et al in 1989 observed that ELBW infants with CLD who went home on oxygen supplementation had good catch-up growth at 19 months. Taken collectively, these data suggest that hypoxic conditions affect growth negatively and supplementing oxygen may improve growth.

The optimal level of oxygen saturation to promote post-natal growth is unknown. Most of the available human data is limited to oxygen supplementation of infants who are oxygen dependent or have BPD. Baraldi et al demonstrated that discharged infants with BPD, who were kept on supplemental oxygen to keep saturations above 94%, had progressive but poor weight gain (stayed below 3rd percentile) at 9 months corrected age follow-up. In infants with BPD whose oxygen supplementation was intentionally discontinued, the subset who exhibited episodes of desaturations below 88-91% had a significant decline in the rate of weight gain as compared to those who maintained saturations above 92% (Moyer-Mileur 1996). Conversely, when two different oxygen saturation control policies (high: 88-98% and low: 70-90%) were retrospectively reviewed in <28

week gestation infants, the infants being cared for in the high oxygen saturation policy units were more likely to weigh less than the 3rd percentile at discharge (45% vs. 17%, Tin 2001). The infants assigned to the high oxygen saturation limits were also more likely to have BPD and ROP.

Recently, the BOOST Trial demonstrated that randomizing infants born <30 weeks gestation who were still on oxygen at 32 weeks postmenstrual age either to standard saturations (91-94%) or to high saturations (95-98%) produced no significant difference in growth at 12 months corrected age. This study, while randomizing infants to two different levels of saturations (conventional and high), only enrolled infants if they were still on oxygen supplementation at 32 weeks PMA and used higher limits than planned by SUPPORT. Our proposal is novel in that randomization to the two oxygen strategies begins at birth and continues for as long as the infants are in supplemental oxygen - by implementing this secondary we will be able to determine the impact of these strategies on short and long-term growth.

Methods:

Anthropometric Measures – at birth, postnatal days 7, 14, 21, and 28 days, 32 w PMA and 36 w PMA or discharge (wt, length, HC)

1. Weight - using standard digital electronic scales (c/o infant's nurse)
2. Length - using the Premie Length Board (average of two values, c/o research staff)
3. Head circumference - using paper measurement tape (average of c/o research staff)

Clinical Data-

1. Date when infant regains birth weight
2. Date of first enteral feed
3. Date of full enteral feeds (enteral > 120ml/kg/d)
4. Total number of days on parenteral nutrition
5. 24 h intake 'snapshots' (Parenteral, Enteral) – postnatal days 7, 14, 21, and 28, 32w PMA, 36w PMA or discharge (whichever comes first)
6. Presence of BPD

Intervention Data –

1. Duration of time spent in target saturation ranges of interest (Already part of SUPPORT‡)
2. Median values for unmasked oxygen saturation while still on supplemental oxygen therapy‡
3. Highest daily FiO_2‡
4. Duration of supplemental oxygen exposure‡
5. Documentation of post-discharge oxygen use

Follow Up data –

1. Anthropometric measurements at 18-22months corrected age
2. Neuro-developmental follow up at 18-22 months corrected age

Primary Outcome:

Growth in-hospital and at 18-22 months corrected age and in-hospital growth trajectories in high and low saturation arms.

Sample Size:

Given the importance of using an RCT to establish the impact of different levels of oxygen saturation from birth on short and long term growth, and recognizing the wealth of oxygen saturation data that will be available for analysis combined with the absence of comparable data in the literature, all infants in the SUPPORT Trial should be recruited into this secondary (n=1320). This sample size will be adequate to detect subtle differences in growth between the two groups with adequate ($\geq$80%) power. For example, this sample size will have at least 80% power to detect a difference in means between the two saturation groups of less than 40 g (assuming a mean weight of 1000 g in the control group and a standard deviation of 250 g) using a two group t-test with a 0.05 two-sided significance level.

Statistical Analysis:

Based upon intent-to-treat, differences between treatment arms with respect to continuous outcomes (such as weight, length, etc.) will be assessed by the Student t-test or the Mann-Whitney U-test, depending upon whether the empirical distribution of the data is approximately normal or heavily skewed. Adjusted analyses will be conducted using linear regression to determine the relationship between measures of oxygen saturation and growth in the presence of covariates and confounders (such as site, gestational age, gender, etc.). Categorical outcomes (such as BPD, growth failure, etc.) will be compared across treatment groups using the chi-square test. Logistic regression models will be developed to determine whether oxygen saturation independently affects growth after correction for confounding variables that also alter growth.

In-hospital growth data will be available over multiple points in time. Outcomes available from this temporal distribution will enable us to perform a longitudinal analysis comparing the trajectories of growth between the two treatment groups. Longitudinal studies are powerful both in terms of explanatory power and statistical efficiency. They are useful in examining whether children in the two different oxygen saturation arms have different developmental trajectories over time. Further, longitudinal studies are statistically more efficient since they acknowledge and account for naturally occurring differences among children, including unmeasured characteristics such as genetic make-up, prenatal exposures, etc.

In order to analyze longitudinal growth data we propose to use hierarchical modeling, where the first stage models growth as a function of time/child's age, and the second stage models this association as a function of each child's

treatment status. This flexible modeling formulation allows each child to have its own unique developmental trajectory, which could depend on its treatment status.

Discussion of Anticipated Results

We anticipate a better growth outcome in-hospital and at 18-22 months corrected age in the infants randomized to the lower target saturation range who maintained their median oxygen saturations within study range. We further anticipate that longitudinal analyses will demonstrate that these infants will have a sustained higher trajectory of growth over time compared to infants in the higher target saturation range.

Budget:

Additional nursing time, needed to collect required anthropometric data and other data from chart review at discharge and at follow-up, is estimated to be 1 hour. The cost for the entire cohort (1320 subjects), at $32.00 per nursing hour, would be $42,220. Assuming a 35% mortality for this extremely preterm population (estimated from GDB), 858 subjects could be expected to survive to discharge and estimating time for survivors alone will reduce the budget to $27,456.00.

Manual of Operations for the NICHD Neonatal Research Network

Post-natal Growth of Infants Enrolled in the NICHD Neonatal Network Oxygen Saturation (SUPPORT) Study

Draft
November 10, 2005

Table of Contents

Chapter 1

Objectives and Trial Design

1.1 Introduction

This manual provides detailed instructions for the secondary study of *Post-natal Growth of Infants Enrolled in the NICHD Neonatal Network Oxygen Saturation (SUPPORT) Study.* The manual is meant to serve as a reference guide for study staff including investigators, coordinators and data managers. The trial objectives and design are summarized briefly below. For further discussion of the study background and design, please refer to the protocol.

1.2 Trial Hypotheses

Post-natal growth restriction is a major problem in preterm infants. Perturbations in oxygenation are recognized to influence post-natal growth; hypoxic conditions can directly impair growth and hyperoxic conditions predispose infants to BPD, which in turn has been linked to poor growth. The NICHD Neonatal Network is conducting a prospective trial of preterm infants randomized to two levels of baseline oxygen saturations. The effect of baseline saturations on pulmonary morbidity and ROP are the primary outcome measures. With respect to post-natal growth, there is a paucity of data relating alterations in baseline oxygen saturation and/or frequent deviations above or below the baseline to growth outcomes. We propose a secondary study to quantify short-term growth velocity in-hospital and long-term growth at 18-22 months of corrected age for infants enrolled in the SUPPORT Trial in relationship to oxygen saturation.

1.2.1 Primary Hypothesis:

1. Infants in the low oxygen saturation group (85-89%) will have better in-hospital and long-term (18-22 months corrected age) growth.

2. Trajectories of growth in hospital will be better for infants in the low oxygen saturation group.

1.2.2 Secondary Hypothesis:

1. Growth will be greater in infants who spend > 50% of the time with daily median oxygen saturation between 85% -95% while on supplemental oxygen, independent of randomization to low or high oxygen saturation.

2. Infants with BPD will have poorer in-hospital and long-term growth than infants without BPD, independent of the saturation randomization arm.

3. Better long-term growth will be positively related to neuro-developmental outcome, independent of the saturation randomization arm.

1.3 Specific Study Aims

a. To determine anthropometric measurements (wt, HC, length) in infants randomized to low and high oxygen saturation arms, from birth to hospital discharge and again at 18-22 months corrected age.
b. To determine nutritional intake (parenteral and enteral) during hospital stay.
c. To determine the percentage of infants with growth <10 percentile at 36 weeks PMA or discharge, whichever comes first.
d. To determine the percentage of infants with growth <10 percentile at 18-22 months corrected age.
e. To determine growth in relation to the proportion of time spent with oxygen saturation
    1. <85% and >95%
    2. 85%-95%
f. To determine growth in relation to infants' median oxygen saturation while in supplemental oxygen
    1. median oxygen saturation > 95%
    2. median oxygen saturation 85% - 95%
    3. median oxygen saturation < 85%
g. To relate incidence of BPD in low and high saturation arms to growth.
h. To determine in-hospital growth velocity/trajectory in low and high saturation arms.
i. To determine long-term growth velocity/trajectory, from hospital discharge to follow up at 18-22 months corrected age in low and high saturation arms.
j. To relate neuro-developmental outcome at 18-22 months corrected age to long-term growth in low and high saturation arms.

1.4 Study Design

This is an Observational Secondary study to the SUPPORT trial. Anthropometric measurements, clinical data, interventional data and follow-up data will be collected at .

1.4.1 Anthropometric Measures

Weight, length and head circumference will be measured at birth, postnatal age 7, 14, 21, and 28 days, 32 weeks postmenstrual age and 36 weeks postmenstrual age or discharge which ever comes first.

1. Weight – using standard digital electronic scales (c/o infant's nurse)
2. Length – using the Premie Length Board (average of two values, c/o research staff)
3. Head circumference – using paper measurement tape (average of c/o research staff)

1.4.2 Clinical Data

1. Date when the infant regains birth weight.
2. Date of first enteral feed.
3. Date of full enteral feed > 120ml/kg/d.
4. Total number of days on parenteral nutrition.
5. 24 hour intake 'snapshots' (parenteral, enteral) – postnatal age 7, 14, 21, and 28 day, 32 weeks postmenstrual age and 36 weeks postmenstrual age or discharge which ever comes first.
6. Presence of BPD.

1.4.3 Intervention Data

1. Duration of time spent in target saturation ranges of interest (already part of SUPPORT[‡]).
2. Median values for unmasked oxygen saturation while still on supplemental oxygen therapy[‡].
3. Highest daily FiO_2[‡].
4. Duration of supplemental oxygen exposure[‡].
5. Documentation of post-discharge oxygen use.

1.4.4 Follow Up data

1. Anthropometric measurements at 18-22months corrected age.
2. Neuro-developmental follow up at 18-22 months corrected age.

1.5 Sample Size

Given the importance of using an RCT to establish the impact of different levels of oxygen saturation from birth on short and long term growth, and recognizing the wealth of oxygen saturation data that will be available for analysis combined with the absence of comparable data in the literature, all infants in the SUPPORT Trial as of the start date of the secondary should be recruited **(n=1320)**. This sample size will be adequate to detect subtle differences in growth between the two groups with adequate (≥80%) power. For example, this sample size will have at least 80% power to detect a difference in means between the two saturation groups of less than 40 g (assuming a mean weight of 1000 g in the control group and a standard deviation of 250 g) using a two group t-test with a 0.05 two-sided significance level.

1.6 Study Outcomes

1.6.1 Primary Outcome

Growth in-hospital and at 18-22 months corrected age and in-hospital growth trajectories in high and low saturation arms.

Chapter 2

Administration

2.1 Organizational Structure

Post-natal Growth of Infants Enrolled in the NICHD Neonatal Network Oxygen Saturation (SUPPORT) Study is being conducted by the NICHD Neonatal Research Network. The Network is funded by the NICHD under cooperative agreements with sixteen institutions comprised of twenty clinical centers and a data coordinating center. The Steering committee for the Network consists of the Principal Investigator from each clinical center, the data center, and the NICHD project officer. The Steering Committee Chairman is appointed by NICHD and is not a Principal Investigator from any of the Clinical Centers. The Post-natal Growth Secondary Protocol Subcommittee is responsible for the preparation and maintenance of the protocol, data forms, and manual of operations. This subcommittee will monitor the overall study performance (including protocol compliance) and will report the progress of the trial to the Steering Committee. The Post-natal Growth subcommittee members are:

Cristina Navarrete
Shahnaz Duara
Richard A. Ehrenkranz
Ruth Everett
Neil Finer
Brenda Poindexter
Abhik Das
Rosemary Higgins

2.2 Participating Centers

Centers from the NICHD Neonatal Research Network participating in the trial are listed with NICHD center numbers in parenthesis and principal investigators listed in the right column.

PARTICIPATING CENTERS	NRN PI	SUPPORT STUDY PI
Case Western Reserve Univ. (3) Rainbow Babies and Children's Hospital	Michele Walsh, MD	Michele Walsh, MD
University of Texas-Dallas (4)	Charles Rosenfeld, MD	Walid Salhab, MD
Wayne State University (5) Children's Hospital of Michigan	Seetha Shankaran, MD	Seetha Shankaran, MD
University of Miami (8) Jackson Memorial Hospital	Shahnaz Duara, MD	Cristina Navarrete MD
Emory University (9) Grady Memorial Hospital	Barbara J. Stoll, MD	Susie Buchter, MD
University of Cincinnati (11) University of Cincinnati Hospital	Edward F. Donovan, MD	Vivek Narendran, MD Kurt Schibler, MD
Indiana University (12)	James A. Lemons, MD	Brenda Poindexter, MD

Yale University (13) The Children's Hospital at Yale – New Haven	Richard A. Ehrenkranz, MD	Vineet Bhandari, MD
Brown University (14) Women and Infant's Hospital	William Oh, MD	Abbot Laptook, MD
Stanford University (15) Stanford University Med Center	David K. Stevenson, MD	Krisa Van Meurs, MD
University of Alabama (16) University of Alabama at Birmingham	Waldemar A. Carlo, MD	Waldemar A. Carlo, MD
University of Texas- Houston (18)	Jon E. Tyson, MD	Brenda Morris, MD
Duke University (19)	Ronald Goldberg, MD	C. Michael Cotten, MD
Wake Forest University (20)	Michael O'Shea, MD	Michael O'Shea, MD
Children's Hospital at Strong (21)	Dale L. Phelps, MD	Nirupama Laroia, MD
University of California-San Diego (22)	Neil Finer, MD	Neil Finer, MD

2.3 Responsibilities of the Clinical Centers

The minimum staff required for network participation at each clinical center is the physician Principal Investigator (PI), the Research Coordinator and/or research nurse. The responsibilities of these individuals are described briefly in this chapter.

The **PI** or designee is responsible for ensuring the proper conduct of the trial at his or her clinical center (including recruitment and treatment of patients as specified in the protocol), accurate collection of data and transmission of information to the Data Coordinating Center (DCC). Other specific duties include the following:

- Presenting an in-service to the other physicians
- Applying for IRB approval
- Introducing the study to the parents of prospective patients, and obtaining signed informed consent from the parents of eligible infants (in some centers this responsibility may be delegated)
- Reviewing all infants for whom informed consent has been obtained to confirm their eligibility
- Informing the IRB of the study progress.

The **Research Coordinator** will be responsible for the day-to-day operations of the study at the clinical center, including data collection and management. This responsibility includes the following:

- Presenting an in-service to the appropriate nursing and ancillary staff and respiratory therapists detailing the study protocol
- Collecting information necessary to complete the data collection forms, and coordinating data entry
- Training and certifying the staff in the use of the network microcomputer

- Controlling access to the network microcomputer and ensuring that required back-up, security and confidentiality are maintained
- Responding to edit messages and other communications from the data enter
- Distributing updates of the protocol and of the manual of operations to clinical center staff
- Reporting protocol deviations (including unmasking) by monitoring the respiratory therapy worksheets

The pharmacist/research nurse will be responsible for randomizing the patient using a randomization list kept at each site.The pharmacist will be responsible for reconstituting the study drug for nebulization. Each infant will be monitored for adequate study drug (aerosol) delivery and for possible toxicity. The responsibilities of the pharmacist/research nurse and the respiratory therapist include the following:

- Developing strategies to maintain masking in cooperation with the PI
- Achieving and maintaining fluency with the procedures for obtaining the treatment group assignment from the data center
- Maintaining the study equipment to facilitate rapid set up and connection, minimizing the time between randomization and initiation of study aerosol.
- Monitoring the infant for signs of toxicity
- Monitoring the study aerosol administration and scavenging equipment for potential environmental contamination
- Completing the safety information and submitting it to the data center within 48 hours of study aerosol discontinuation
- Monitoring adherence to the protocol with respect to study aerosol management, and reporting deviations to the data center within 24 hours of occurrence

2.4 Responsibilities of the Data Coordinating Center

The DCC is responsible for all aspects of statistical design and analysis as well as data management of the study. In particular, this includes:

- Processing, updating and distributing the protocol and manual of operations
- Developing, printing and distributing the data forms, including periodic updates as necessary
- Developing, testing and implementing the database and other software. Ensuring that data are correct and complete by implementing editing and auditing procedures
- Monitoring the progress and quality of the study
- Preparing interim and final analyses and reports
- Participating in the preparation of presentations and publications relating to the study.

2.5 Responsibilities of NICHD

In addition to its role as a funding agency, the NICHD participates in the activities of the cooperative agreement by being represented on the Steering Committee. The Program Official also participates in the development of protocol and in assisting the Steering committee in the coordination of the studies conducted by the Network. The NICHD Program Official, in conjunction with the RTI Principal Investigator is responsible for monitoring site performance of all participating centers. The Program Official has the following responsibilities:

- Assistance in the development of the study protocol.
- Assistance in the development of capitation-based budgets, including the identification of study costs and special institutional needs.
- Allocation of network resources to meet study needs including pharmacies, study drug supply, and other special requirements of the study.
- Facilitation of training meetings, site visits, and subcommittee meetings.
- Participating in preparation of publications.

Chapter 3

Study Forms

3.1 Nutritional Intake Form: (GRO-01)

This form will be completed on all enrolled infants on days 1, 7 (±1d), 14 (±1d), 21 (±1d) and 28 (±1d), and on postmenstrual age 32 and 36 weeks or discharge whichever comes first. Plus/minus one day (±1) will entail assessing infant 24 hours before actual data collection day for severity of illness as per clinical team (attending, fellow, or nurse) that would preclude anthropometric measurements. If the infant is too ill for measurements, re-assessments are to be made for the next 48 hours.

3.1.1 Instructions for Completing Form GRO-01 (Nutritional Intake Form)

- **Center Number**
  Each study center has been assigned a Network center number.

- **Site**
  The center assigns these to their various hospitals. If applicable, any site letter or number is acceptable.

- **Network Number**
  The Network number is made up of a four digit Family (Pregnancy) Number plus the Birth Order Number. Therefore the Network Number is 5 digits.

- **Birth Number**
  This code distinguishes between siblings in the NICU. A single birth or first born of a multiple birth will be coded '1', '2', etc. It does not necessarily have to conform to strict birth order from a multiple birth, but must be kept consistent for each baby.

- **Mother's Initials**
  The Mother's normal initials (first, middle and last). If there is **no** middle initial, record the two initials. **This information is optional.**

- **Report Number**
  The Report Number is a sequential number, starting with number 1, documenting the number of times this form has been completed. (i.e., DOL 1 = report number 1; DOL 7 = report number 2 etc.)

1. Date
Record the date in MM/DD/YYYY format in which the day of life and the information correspond.

2. Day of life
Day one of life is the day that the baby is born. All data will be entered under the corresponding day of life.

3. Is the infant medically stable to obtain anthropometrics?
If yes, continue to #4
If no, re-assess within the next 48 hours for clinical stability. If deemed unstable for handling by the end of the 48 hour time frame, leave the space for the unavailable anthropometric measurements marked by *.

4. Today's New Weight
Document weight in grams as recorded by the bedside nurse.

5. Today's New Length
Document length in centimeters, rounded off to the nearest tenth. Measurements should be obtained by the research staff using the Premie Length Board, the infant is placed supine on the board (without a diaper). One examiner holds the infant's head horizontal and aligned to the spine so that there is no lateral tilt of the head or rotation of the chin from the midline. Gentle traction is applied to bring the top of the head into contact with the fixed headboard. The second examiner holds the infant's feet, toes pointing directly upward, and applies gentle traction to straighten the legs. The moveable footboard is brought to the feet and a measurement is taken when it is pressed firmly against the infant's heels. The length must be documented to the nearest tenth. Two measurements are taken and if they are within 1 cm of each other, the average is recorded. If the measurements are not within 1 cm of each other, a third measure should be taken and the median of the three is recorded.

6. Today's New Head Circumference
Document head circumference in centimeters rounded off to the nearest tenth. Measurements should be obtained by the research staff by applying a measuring tape firmly around the head above the supraorbital ridge (most prominent part of the forehead), and over the occiput to give the maximum circumference. Two measurements should be taken, if the measurements are within 0.5 cm of each other, record the average. If they are not within 0.5 cm of each other, a third measure should be taken and the median of the three should be recorded (to the nearest tenth).

SECTION A. PARENTERAL NUTRITIONAL INTAKE

1. Was there parenteral intake?
If yes, complete question 2

2. For each 24-hour period record the following information for each bag of parenteral nutrition.

- Percent dextrose: Record the percent dextrose solution of the given bag of parenteral nutrition
- Amino acids: Record the number of grams/kg/day of amino acids ordered by the physician for this bag of parenteral nutrition (record to the nearest tenth) OR record the concentration of amino acids in grams per liter in a given bag
- Record PN volume received: Enter the volume in cc of parenteral nutrition the infant received from the given bag during the 24 hour period
- Intralipids: Enter the percent solution used (10 or 20%) and the total volume in cc of intralipids that the infant received during the same 24 hour period

SECTION B. ENTERAL INTAKE

1. Was there enteral intake?
If yes, record the following for each:

- Type:
  Record the type code from the Enteral Nutrition Key table (found at the bottom right corner of the form), corresponding to the type given during the 24 hour period. If infant was NPO for the 24 hour time period, record "00" and the remainder of this section should be left blank for the given day
- Caloric Density:
  Document the total caloric density per ounce of the feeding type given. See Appendix.
- Volume received:
  Record the total amount of the particular feeding type given in the 24 hour time period (in cc's to the tenth).
- Nutrient additives:
  Use the codes listed in the Enteral Nutrition Key table to document the use of MCT or other oil, Polycose, human milk fortifier, or liquid or powder formula added to the feeding.

APPENDIX A

Caloric density:

Milk Formula	Full strength (kcal/oz)	½ strength (kcal/oz)
Expressed breast milk Enfamil Premature Formula 20 Similac Special Care 20 Pregestimil 20 Nutramigen Similac 60/40 Isomil/ProSobee Alimentum Neocate	20	10

Marie and Abhik
I just wanted to make sure that we are following nasal breakdown. If things are ok within the groups, it is fine. If there is an excessive incidence in one group – that should be referred to the DSMC.

Thanks
Rose

Hi Abhik,

Nasal breakdown is one of the outcomes we currently look at, in combination with other AEs. Does she want to look at that event separately?

Marie:

Rose thinks we ought to look at Nasal breakdown requiring discontinuation of nasal prongs by treatment group as well when we do our periodic safety looks.

Thanks

Subject: SUPPORT Breathing Outcomes - FU Coordinator Call 11/17
Date: Thursday, November 10, 2005 9:42:42 AM
Attachments: Breathing Brochure11_10.doc

Dear Follow-up Coordinators,

Attached is the Breathing Brochure (formerly the Breathing Diary, which has been shortened). This along with the study documents distributed to you on 11/3 (Forms, Manual, and Protocol) will be discussed on Thursday November 17 from 2-3pm.

We ask that all Follow Up coordinators join the Breathing Outcomes portion and for Inositol, just the sites participating in the Cross Sectional study. However, all are welcome to join.

Agenda
Thursday, November 17

2:00-3:00pm Breathing Outcomes
3:00-4:00pm Inositol Cross Sectional Study (Indiana, Yale, Brown, Stanford, Duke, Wake Forest, Rochester)

Dial toll free: **1-888-994**(b) (6)
Passcode: (b) (6) (then press #)

Please let me know if you have any questions.

Thanks, Jamie

Subject: SUPPORT Breathing Outcomes - FU Coordinator Call 11/17

Dear Follow-up Coordinators,

Attached are the SUPPORT Trial Breathing Outcomes Study documents revised after the call on Tuesday November 1. Due to the confusion with the SUPPORT Follow-up Study and due to IRB concerns with long study titles with multi-syllable words, the title of this study has been changed to the "Breathing Outcomes Study" . We would like to have a call with the coordinators to hear your comments on the Manual and Forms. Several of you have Thursday, November 17 at 2pm already blocked off for the routine NRN Coordinators call. Please let me know if you will be able to join the call from 2-3pm so that we can have a head count of who to expect.

The breathing brochure (formerly the breathing diary) will be distributed to you next week. Please let me know if you have any questions.

Thanks, Jamie

NICHD NEONATAL RESEARCH NETWORK

NICHD SUPPORT Trial
Breathing Study

Premature babies are more likely than full term babies to have breathing problems after discharge from the NICU. The purpose of this study is to see whether the treatment your baby received as part of the SUPPORT Study improves your baby's breathing in the 18-22 months following the baby's due date.

As part of this study, we will contact you every 6 months or so to ask you questions about your baby's breathing. The questions will be about your baby's breathing symptoms, especially wheezing and coughing, and about your baby's need for medical visits and treatments for breathing problems.

Wheezing can mean different sounds to different people. By wheezing, we mean an expiratory sound (a sound that is made when breathing out, not in) that comes from the chest, sometimes described as whistling or musical.

To help us understand your baby's breathing, please note how often your baby has wheezing or coughing, whether your baby visited a doctor's office, emergency room or was hospitalized for breathing problems and what medications your baby needs.

Feel free to use the back of this brochure, a calendar or another sheet to make notes that help you keep track of your baby's breathing.

When we call, we'd like you to gather any notes, medications or other information about your baby's breathing. As with all information we collect, the answers to these questions will be kept confidential.

TABLE OF CONTENTS

Study Protocol

ABSTRACT

Statement of Problem Premature infants have a greater risk of recurrent wheezing and chronic cough and greater need for pulmonary care in early childhood than term infants (1-11). Although Chronic Lung Disease (CLD) is a risk factor, the etiology of symptomatic airway dysfunction, defined hereafter as recurrent wheezing and/or chronic cough, in formerly premature infants is not known.

Hypotheses The goal of this clinical project is to understand better the antecedents of symptomatic airway dysfunction among preterm infants during early childhood by evaluating the effect of treatment with different levels of targeted oxygen saturation in the immediate neonatal period. **The overarching hypothesis is that premature infants exposed to supplemental oxygen suffer oxidant stress in the lung in the immediate newborn period that results in impaired airway growth and development. These airway changes predispose premature infants to greater airway dysfunction and respiratory symptoms when challenged with subsequent environmental or infectious exposures.**

Hypothesis #1- Relative to infants managed with a higher SpO2 range, infants who are managed with a lower targeted SpO2 range will have less symptomatic airway dysfunction and reduced need for outpatient pulmonary care in the first 18-22 months' corrected age (CA), whether they develop CLD or not.

Hypothesis #2- Relative to infants managed with prophylactic surfactant and conventional ventilation, infants who are managed with the early use of CPAP and a permissive ventilator strategy will have less symptomatic airway dysfunction and reduced need for outpatient pulmonary care in the first 18-22 months' CA, whether they develop CLD or not.

Design

This study is a longitudinal follow-up of infants enrolled in the SUPPORT Trial to determine the effect of lower targeted oxygen saturation ranges and more aggressive use of CPAP on the incidence of symptomatic airway dysfunction and volume of outpatient pulmonary care in the first 18-22 months' CA.

Definition of outcomes:

A) Parental Report Symptomatic Airway Dysfunction Defined as Recurrent Wheezing or Chronic Cough
B) Parental Report of Physician Diagnosed Wheezing
C) Volume of Outpatient Pulmonary Care including number of pulmonary medications, office and emergency room visits and re-hospitalizations for respiratory illnesses.

Ascertainment of outcomes:

Outcomes will be measured at 4 time points in the first 18-22 months' CA as follows:

1. NICU discharge -baseline interview at to obtain family and environmental history
2. Six months' CA - telephone or face to face interview to ascertain incidence of symptomatic airway dysfunction and obtain interval history of need for pulmonary care.
3. Twelve months' CA - telephone or face to face interview as at 6 months'
4. 18-22 months' CA- Prior to or as part of the NICHD follow-up clinic visit, a telephone or face to face interview will be conducted to ascertain incidence of symptomatic airway dysfunction and obtain history of need for pulmonary care.

Anticipated Results

We anticipate that, for infants who develop CLD and those who do not, treatment with a lower vs. higher targeted oxygen saturation range will have less symptomatic airway dysfunction and less need for outpatient pulmonary care in the first 18-22 months' CA. We also anticipate that greater use of CPAP compared with conventional management will be associated with less symptomatic airway dysfunction.

Benefits and Risks

The proposed SUPPORT Breathing Outcomes Study will directly measure symptomatic airway dysfunction and outpatient pulmonary morbidity in infants treated with either a higher vs. lower targeted oxygen saturation. These data will provide important insight into the effect of different levels of supplemental oxygen exposure on airway growth and development in formerly premature infants. In addition to creating a potential model for outpatient pulmonary follow up, the proposed follow on study may improve follow up at the 18-22 month NICHD visit by maintaining contact with families during the interval between NICU discharge and the neurodevelopmental follow up visit. We anticipate no risk to patients enrolled in this observational follow-up study.

B. STATEMENT OF THE PROBLEM

Premature infants have a greater risk for recurrent wheezing, chronic cough and more need for pulmonary care in early childhood than term infants(1-11). Although Chronic Lung Disease (CLD) is a risk factor, the etiology of symptomatic airway dysfunction, defined hereafter as recurrent wheezing and/or chronic cough, in formerly premature infants is not known.

C. HYPOTHESES

The overarching hypothesis is that premature infants exposed to supplemental oxygen and, to a lesser extent, mechanical ventilation, in the immediate neonatal period suffer oxidant stress in the lung that results in impaired airway growth and development. These airway changes predispose premature infants to greater airway dysfunction, respiratory symptoms and need for pulmonary care when challenged with subsequent environmental or infectious exposures.

Specific Hypotheses:

Hypothesis #1- We hypothesize that relative to infants managed with a higher SpO2 range, infants managed with a lower SpO2 range will have less frequent episodes of symptomatic airway dysfunction and reduced need for outpatient pulmonary care at 18-22 months' CA.

Hypothesis #2- We hypothesize that relative to infants managed with prophylactic surfactant and conventional ventilation, infants managed with early CPAP and permissive ventilator strategy will have less frequent episodes of symptomatic airway dysfunction and reduced need for outpatient pulmonary care in the first 18-22 months' CA.

Hypothesis #3- We hypothesize that **among infants with CLD**, infants managed with a lower SpO2 range relative to those managed with a higher SpO2 target range and infants managed with early CPAP and permissive ventilator strategy compared with those managed with prophylactic surfactant and conventional ventilation will have less frequent episodes of symptomatic airway dysfunction and reduced need for outpatient pulmonary care during the first 18-22 months' CA.

Hypothesis #4- We hypothesize that **among infants without CLD**, infants managed with a lower SpO2 range relative to those managed with a higher SpO2 target range and infants managed with early CPAP and permissive ventilator strategy compared with those managed with prophylactic surfactant and conventional ventilation will have less frequent episodes of symptomatic airway dysfunction and reduced need for outpatient pulmonary care during the first 18-22 months' CA.

D. SPECIFIC AIMS

The goal of this project is to understand better the etiology of symptomatic airway dysfunction among formerly premature infants during early childhood by examining the interaction of oxygen exposure (targeted SpO2 range), surfactant therapy and early nasal CPAP in the newborn period.

SA#1 - Measure the effect of lower vs. higher targeted SpO2 on the incidence of symptomatic airway dysfunction and volume of outpatient pulmonary care among infants born $24^{0/7}$ - $27^{6/7}$ weeks' gestation during the first 18-22 months' CA.

SA#2 - Measure the effect of early CPAP and permissive ventilator strategy compared with prophylactic surfactant and traditional ventilator strategy on the incidence of symptomatic airway dysfunction and volume of outpatient pulmonary care among infants born 24-27 weeks' gestation during the first 18-22 months' CA.

SA#3 – Among infants who develop CLD, determine whether CLD is milder in infants managed with low compared with high targeted SpO2 by measuring incidence of symptomatic airway dysfunction and volume of outpatient pulmonary care. A similar analysis will be performed by SUPPORT Trial ventilatory strategy assignment, i.e. early CPAP and permissive ventilation compared with prophylactic surfactant and traditional ventilation.

SA#4 – Among infants who do not develop CLD, determine whether pulmonary outcome is better for infants managed with a low compared with high targeted SpO2 range by measuring incidence of symptomatic airway dysfunction and need for outpatient pulmonary care. A similar analysis will be performed by SUPPORT Trial ventilatory strategy assignment, i.e. early CPAP and permissive ventilation compared with prophylactic surfactant and traditional ventilation.

E. RATIONALE/JUSTIFICATION

Although synergy in producing airway injury may exist between oxygen toxicity and mechanical forces applied to the lung, animal and human data suggest that exposure to high concentrations of supplemental oxygen alone is sufficient to cause airway narrowing and greater airway dysfunction when exposed to subsequent environmental or infectious challenges. Understanding the relative contributions of oxygen toxicity and mechanical forces on airway growth and development may facilitate development of targeted therapies for preventing or reducing symptomatic airway dysfunction in premature infants.

Why measure symptomatic airway dysfunction and outpatient pulmonary care as an outcome from a clinical NICU interventional trial?

1) Important information will be available on the effect of oxidant gas exposure on airway development and later symptomatic airway dysfunction. Exposure to oxidant gas has been causally linked with later wheezing. Existing data on the relationship between supplemental oxygen therapy and wheezing come from longitudinal cohort studies, a design that suffers from intrinsic limitations that make controlling for potential confounders of respiratory outcome difficult. By randomizing infants to higher vs. lower target saturation ranges, and thereby presumably higher or lower concentrations of inspired oxygen, *the SUPPORT Trial creates a unique, and perhaps the only, opportunity to evaluate the effect of different levels of supplemental oxygen on subsequent symptomatic airway dysfunction and need for outpatient pulmonary care after NICU discharge.*
2) Using clinical measures of outpatient pulmonary morbidity, the effect of NICU based respiratory interventions on respiratory health and need for outpatient medical care can be directly quantified, allowing assessment of whether infants both with and without CLD have improved pulmonary health as a result of the study intervention.
3) The incidence of CLD, defined as an oxygen requirement at 36 weeks' PMA, is an incomplete measure of pulmonary outcome in formerly premature infants during early infancy. CLD as defined above reflects alveolar gas diffusion and NICU oxygen needs. However, outpatient pulmonary morbidity for formerly premature infants is often airway related, involving wheezing either as a primary symptom such as bronchiolitis or as a complicating symptom of lower respiratory tract infection such as pneumonia. The studies proposed here will directly measure the effect of a randomized NICU-based clinical intervention on symptomatic airway dysfunction and outpatient pulmonary morbidity.
4) The risk of a negative trial is reduced. Because the diagnosis of CLD does not completely predict need for outpatient pulmonary care, clinically significant improvements in pulmonary morbidity may occur with minimal or no change in the incidence of CLD. This result has occurred in other interventional trials in which no difference in CLD were observed (12).
5) At present, there is no standard way to measure symptomatic airway dysfunction in premature infants in NICHD pulmonary intervention trials. There is need for a better measure to assess clinical pulmonary outcome to recognize and promote therapies that reduce need for outpatient care of former extremely premature infants.

F. BACKGROUND / PREVIOUS STUDIES

Recurrent Wheezing In Preterm Infants is a Significant Public Health Problem

Outpatient pulmonary morbidity, especially recurrent wheezing and need for outpatient pulmonary care, is an understudied but clinically important outcome measure for former premature infants with and without CLD. Infants born weighing < 1500 grams (very low birth weight, VLBW) and especially infants born weighing < 1000 grams are at increased risk for small airway narrowing, airway hyperreactivity, wheezing, and nighttime cough (1-11). Up to 30-40% of formerly extremely premature infants have episodes of wheezing after NICU discharge

with many requiring bronchodilators and frequent health care visits. Up to 40-50% of premature infants require re-hospitalization, mostly for treatment of respiratory illnesses (9;12;13). In analysis of cross sectional data from the National Maternal Infant Health Survey and 1991 Longitudinal Follow up Survey, the prevalence of asthma-like recurrent wheezing varied markedly with birth weight. Infants with normal birth weight (NBW, > 2500 grams) had a 6.7% prevalence of asthma compared to 10.9% of low birth weight infants (LBW, 1500-2499 grams) and 21.9% for VLBW (14). Mean per capita asthma related costs have been estimated to be 5 times greater for VLBW compared with NBW infants. The net effect is that VLBW infants, who comprise 2% of asthma patients, consume up to 7% of asthma-related therapy costs (14).

Animal Studies

Animal studies suggest that exposure of the premature lung to hyperoxia (without concomitant mechanical ventilation) for relatively brief periods is sufficient to cause airway remodeling and smooth muscle changes that predispose toward airway narrowing and hyperreactivity to subsequent environmental challenges (15-18). In a rhesus monkey model of asthma, Schlegle et al. exposed infant monkeys to repeated cycles of inhaled House Dust Mite Allergen (HDMA), ozone or filtered air. While repeated exposure to either ozone or HDMA had mild effects, exposure to cycles of ozone followed by HDMA resulted in asthma like changes with significant increases in serum IgE, serum histamine, peripheral eosinophilia and greater airway reactivity. Using supplemental oxygen rather than the stronger oxidant ozone, Schulman et al. found that exposure of newborn guinea pigs to 70% oxygen for 96 hours resulted in airway hyperreactivity at 2 and 9 days after the cessation of oxygen. In cell models, intracellular glutathione buffers airway cells against oxidant injury during hyperoxia (19;20). Although the critical period for lung development is comparatively brief in laboratory animals compared with human infants, the duration of hyperoxic exposure (and risk of oxygen toxicity) for treatment of neonatal lung disease may extend for much longer periods in premature infants known to be deficient in anti-oxidant systems such as intracellular glutathione.

Premature Infants <u>With CLD</u> Are At Greatest Risk For Airway Dysfunction

Among premature infants, infants with bronchopulmonary dysplasia (BPD) are at highest risk for poor pulmonary outcome after NICU discharge. Infants with CLD have small airway compromise with decreased forced expiratory flow velocities, airway hyperreactivity, and increased functional residual volume suggesting airway obstruction (2;5;9;21-24). In a pulmonary follow up of infants with RDS or BPD, De Klein et al. found infants with BPD had reduced FEV1 at baseline while infants with RDS but not BPD had significant improvements in FEV1 following bronchodilator therapy. In this study, a history of recurrent wheezing predicted abnormal pulmonary function (25). In a recent study of infants with CLD, Robin et al. found that 50% of infants with CLD had symptoms of recurrent wheezing and 35% showed significant airway responsiveness to bronchodilators, evidenced by a 24% increase in forced expiratory flow velocity at 75% of expired forced vital capacity (FEF_{75}). This study demonstrated the relationship between recurrent wheezing as a clinical symptom and the physiologic measurement of airway obstruction. Infants with CLD and a history of recurrent wheezing showed greater hyperinflation, expiratory flow limitation and airway responsiveness to albuterol compared to those without a history of recurrent wheezing (24).

Premature Infants <u>Without CLD</u> Have Significant Airway Dysfunction

Among VLBW infants who do not develop CLD, several studies of pulmonary outcome have found an association between neonatal oxygen exposure and increased prevalence of expiratory flow dysfunction and airway hyperreactivity (4;11;26-29). Some authors attribute reductions in airway function to intrinsically small airways as a consequence of poor intrauterine growth rather than superimposed airway injury or reactivity from neonatal respiratory disease (1;30). However, because small airways alone do not fully explain airway hyperreactivity, other mechanisms of small airway dysfunction are necessary to explain respiratory symptoms.

Several pulmonary outcome studies have reported significant increases (2-fold or more) in airway obstruction among VLBW infants without CLD following exposure to as little as 40% oxygen for 5 days (3;4;8;26). Not all studies have had similar results suggesting variability in effect or susceptibility of babies to oxygen exposure (31;32). In 1982, Coates et al. described increased small airway resistance at 10 year follow up of mildly

premature infants (mean gestational age 31 weeks and birth weight 2000 grams) treated with a high oxygen regimen and those exposed to a low oxygen regimen for the treatment of respiratory distress syndrome (RDS). Mechanical ventilation was not used in either group. Pulmonary function tests were performed on survivors receiving either the low or high supplemental oxygen regimen ten years after their initial illness. Infants treated with high levels of supplemental oxygen alone (no mechanical ventilation) had decrements in airway function similar to decrements in function reported for a historical cohort of RDS survivors treated with ventilation and high levels of supplemental oxygen. From these data, the authors concluded that neonatal exposure to high oxygen concentrations in the absence of mechanical ventilation is capable of causing long-term change in small airways (28). These studies suggest that use of lower supplemental oxygen concentration may improve respiratory health of infants who do not develop CLD.

Premature Infants Without CLD Have Increased Risk of Symptomatic Airway Dysfunction and Need for Outpatient Pulmonary Care.

For VLBW infants without CLD, the prevalence of parental or physician reported wheezing is increased compared with term infants, with estimates of the prevalence of wheezing ranging from 10-38% (4;8). Prevalence of wheezing requiring medications is greater compared with term infants. VLBW infants have a 2-4-fold increase in respiratory related re-hospitalization rates compared with term infants (4;8;33-35). Although most studies have found the risk of recurrent wheezing remains elevated throughout childhood, an Australian longitudinal follow-up cohort of VLBW infants found the prevalence of wheezing remained elevated for 2 years then returned to baseline (32;36).

Prevalence of Symptomatic Airway Dysfunction in Formerly Preterm Infants During the Surfactant Era Remains High

With the advent of surfactant therapy, survival of small infants increased dramatically and the incidence of CLD changed minimally (37-40). Classic BPD evolved into the "new CLD" characterized by reduced alveolarization and more variable airway changes (41). Pulmonary follow up studies during the surfactant era showed reduced pulmonary morbidity in surfactant treated patients. Typical of these studies, Sell et al. found the incidence of asthma was significantly lower in infants given synthetic surfactant compared with those given air placebo. Pelkonen et al. performed PFT measurements on 40 children aged 7-12 years who were born before 30 weeks of gestation with an immature surfactant system, and were randomized to one of three treatment groups: prophylactic surfactant, rescue surfactant and placebo (air). Spirometric parameters of children born preterm were compared with those of 20 children born at term. Bronchial obstruction was found in 53% of the prophylactically treated group, in 36% of the rescue group, in 67% of the placebo group, and in 0% of the control group (42). A recent report suggests that the introduction of surfactant therapy markedly altered the pulmonary outcome of premature infants. Published in 2001, the Newborn Lung Project Group reported results of a prospective 12-year follow-up of VLBW infants following the introduction of surfactant therapy (5;8;43). Among infants with CLD, wheezing symptoms decreased from 50 to 16% from the period before compared with the period after surfactant therapy became available. However, among infants without CLD the prevalence of wheezing increased from 14% to 38% with the introduction of surfactant. These data suggest that surfactant therapy has an effect on outpatient respiratory health and underscores the need to consider outpatient pulmonary outcomes in evaluating therapeutic strategies that potentially decrease surfactant replacement therapy.

CLD is an Incomplete Predictor of Outpatient Pulmonary Morbidity

Several authors have looked to respiratory symptoms and need for outpatient pulmonary care as outcome measures for neonatal lung disease (9;10;12;24). In 1988, from a retrospective chart review of 605 premature infants < 1500 grams, Shennan et al. found that the presence of BPD (oxygen requirement at 36 weeks PMA) had a 63% positive predictive value and a 90% negative predictive value for abnormal pulmonary outcome in the first 2 years of age. However, this study from before the era of exogenous surfactant therapy defined abnormal pulmonary outcome as death, oxygen requirement at 40 weeks PMA, 2 or more respiratory related hospital admissions, wheezing requiring drug therapy or persistent wheezing resulting in growth failure, handicap or hypotonia at 1 year of age. Such restrictive criteria for abnormal pulmonary outcome are likely to underestimate the burden of recurrent wheezing on former premature infants and their families. Several recent

interventional studies show that CLD is an incomplete predictor of clinical wheezing and need for outpatient pulmonary care and suggest that differences in oxygen exposure or oxidant stress may affect pulmonary outcome without affecting the incidence of CLD.

Interventional Trials That Did Not Reduce CLD But Did Reduce Outpatient Pulmonary Morbidity.

Recent data in preterm infants treated with human recombinant superoxide dismutase (SOD) found that anti-oxidant therapy did not reduce the incidence of CLD. However, among infants < 27 weeks gestation, SOD therapy resulted in significant reductions in the first year after NICU discharge in the number of emergency room visits and number of re-hospitalizations for respiratory problems and reductions in the need for bronchodilators suggesting a reduced prevalence of wheezing in patients treated with SOD (12). In a randomized, multi-center trial from Helsinki, N acetyl cysteine did not reduce the incidence of CLD. Outpatient pulmonary outcome of these patients has not been reported.

Treatment of Premature Infants With Higher Targeted Oxygen Saturations Is Associated with Poorer Pulmonary Outcome

In the STOP-ROP Study, infants exposed to higher levels of oxygen to achieve a targeted saturation of 96-99% compared with 89-94% had greater risk of adverse pulmonary events including pneumonia, chronic lung disease exacerbations and need for diuretics, oxygen and hospitalization at 3 months' corrected age. *Although all infants in this study had CLD at enrollment, different targeted oxygen saturations were associated with large differences in pulmonary morbidity.* Adverse pulmonary outcomes occurred with differences in FIO2 of as little as 10% for patients treated with ventilation, CPAP or hood (36% $\pm$ 14% vs. 46% $\pm$ 20%, respectively for low vs. high saturation range) and 5% for infants treated with nasal cannula, (26% $\pm$ 6% vs. 31% $\pm$ 11%, respectively for low vs. high saturation range) (44). In a similar study, The Benefits of Oxygen Saturation Targeting (BOOST) Trial randomized infants < 30 weeks' gestation to higher (95-98%) or lower (91-94%) saturations ranges beginning at 32 weeks' PMA to determine whether infants managed with higher targeted saturation range showed better growth and neurodevelopment. As in the STOP-ROP study, need for oxygen therapy was prolonged. Trends towards an increased risk of pulmonary death and fewer outpatient office visits (median 27.5 vs. 31.3, $p < .11$) were seen in the lower targeted oxygen saturation group (13).

Factors In Addition To Prematurity and Oxygen Contribute To Symptomatic Airway Dysfunction

Multiple factors in addition to prematurity and oxygen contribute to the development of airway dysfunction in children (Table 1). In the SUPPORT TRIAL Breathing Outcomes Study, these potential covariates will be measured and controlled for using a randomized trial design. These covariates will also be evaluated as independent predictors of pulmonary outcome in multivariate analyses.

Table 1. ***Important Covariates in Etiology of Recurrent Wheezing***

Demographcis – race, sex, ethnicity, parental factors (educational level, poverty status, and age), and family history of wheezing or atopy.

Environmental – daycare, siblings, crowding, tobacco smoke or wood smoke in the home, pets

Health Services – health care and respiratory medication use appropriate for level of respiratory symptoms

Medical- congenital anatomic airway abnormalities, neonatal sepsis, RSV and other viral infections

G. METHOD/ PROCEDURES

NICHD SUPPORT Trial Breathing Outcomes Study

G.1 Description of study design

This study will add an 18-22 month longitudinal, prospective follow-up study of surviving infants enrolled, randomized and treated as part of the multi-center NICHD Neonatal Research Network SUPPORT Trial.

G.2 Definition of study population

Infants with gestational age of $24^{0/7}$-$27^{6/7}$ weeks' gestation by best obstetrical estimate.

Inclusion criteria:

- Enrollment in the SUPPORT Trial
- Survival to hospital discharge
- Consent for enrollment into the Breathing Outcomes Study, obtained either at the time of enrollment into the SUPPORT Trial or separately.

Exclusion criteria

- Refusal of informed consent

G.3 Description of study intervention

Before delivery, infants will be randomized to subsequent management with high vs. low target oxygen saturation according to the SUPPORT Protocol. The SUPPORT Breathing Outcomes Study begins just prior to NICU discharge (Figure 1).

Figure 1.

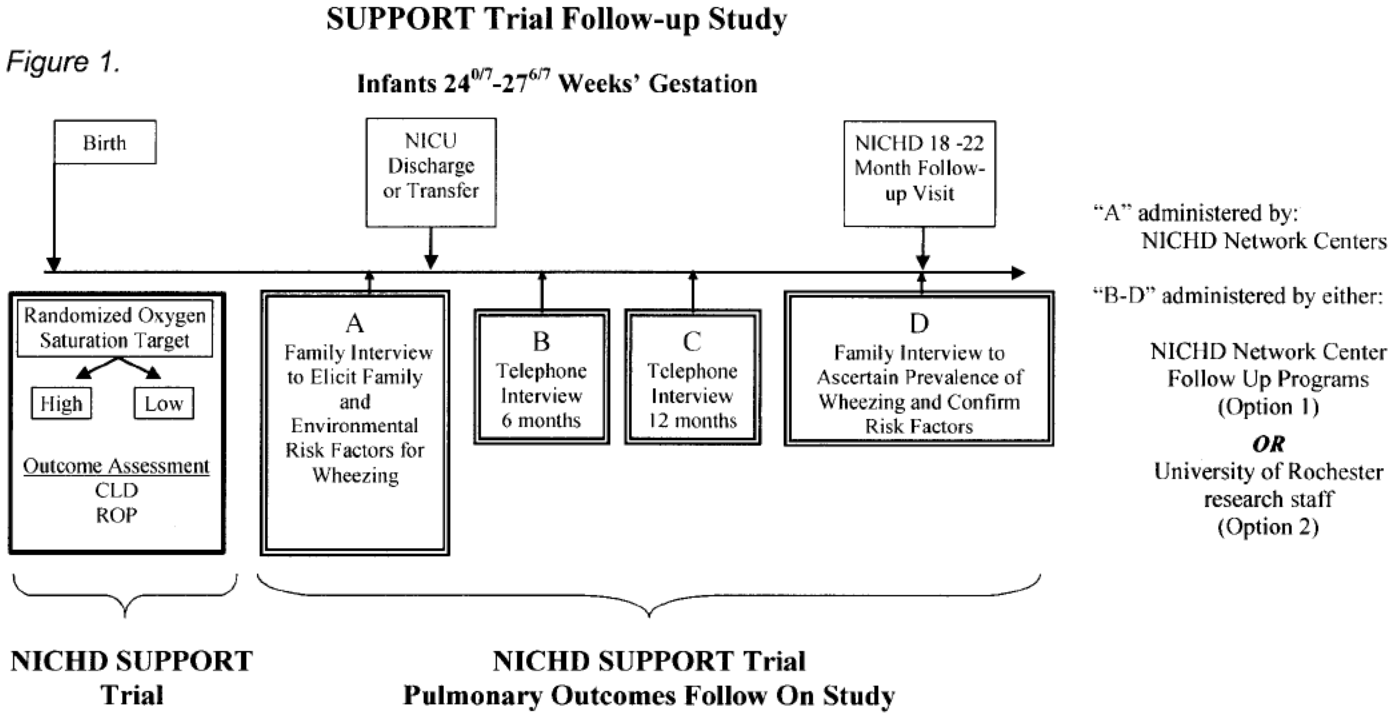

Fig 1, A. Parent (Guardian) Interview to Elicit Family and Environmental Risk Factors for Wheezing and Cough The family interview will be administered either face to face or by telephone to study

participants by site study staff prior to or within 30 days of NICU discharge. The questions are based on intake questions used by the Tucson Respiratory Study and are designed to elicit family history of asthma, atopy, and home environmental exposures and to identify likely care givers (NICU Discharge – Baseline Interview).

Fig 1, B. *Interview at 6 months PMA* – respiratory interval history

Fig 1, C. *Interview at 12 months PMA* – respiratory interval history

Interviews will be undertaken at 6 and 12 months to obtain an interval history of respiratory problems including wheezing, cough, medications used, and health services sought for respiratory related problems (6 and 12 Month Questionnaire). Interviews may be administered either by telephone or face to face.

Fig 1, D. *Parental Interview to Ascertain Incidence of Wheezing and Cough and Confirm Risk Factors*

This parent interview may also be administered either by telephone prior to the regularly scheduled 18-22 month NICHD developmental follow up clinic visit or face to face at the time of the visit. Contacting parents prior to the office visit will help improve the Developmental Follow Up Clinic attendance rate and will allow the clinic visit to provide a back up means to contact the family. The 6, 12 and 18-22 month interviews will be conducted either by the local NICHD Follow Up Program (Option 1) or long distance from Rochester (Option 2), based on center preference (see table 2 below). The interview questionnaires are based on questionnaires administered by the Tucson Respiratory Study at approximately one year of age (18-22 Month Questionnaire). Questions are designed to ascertain the frequency and severity of wheezing and cough episodes and to assess need for outpatient pulmonary care. In addition, risk factors obtained at the 1st interview will be confirmed.

Each interview will collect a 6 month interval history, which, when taken together, will provide a complete respiratory history over the first 18-22 months' corrected age. If one questionnaire is not completed, the subsequent questionnaire will include the full interval history since the last completed questionnaire.

To standardize administration of the interview, the Rochester site will lead an interviewer training program consisting of two parts. Part 1 will consist of a teleconference to discuss study questions and interview script in question by question detail. Part 2 will consist of a practice interview in which interviewers from each center interview the Rochester trainer, who simulates a standardized patient. Following the practice interview, the Rochester trainer and practice interviewer will discuss the interview and give feedback. All interviewers will be required to complete this training.

G.4 Precise definition of co primary/secondary outcomes

G.4.1 Definition of primary outcomes- parental report of recurrent wheezing and chronic cough.

Two primary outcomes will be measured, the incidence of recurrent wheezing and incidence of chronic cough. Whether individual symptoms (recurrent wheezing or chronic cough, alone) or a combination of these symptoms (wheezing and/or chronic cough, together) best quantifies symptomatic airway dysfunction following premature birth is controversial. Many studies have used wheezing alone as a primary outcome measuring pulmonary morbidity in formerly premature infants (10;12;14;48). In 1996, Greenough, using a combined outcome of either wheezing or chronic cough as a measure of symptomatic airway dysfunction, found that greater pulmonary symptoms were associated with longer durations of supplemental oxygen and mechanical ventilation (49;50). Later, in a follow-up study of infants enrolled in The United Kingdom Oscillator Study (UKOS), Greenough found that frequent wheezing episodes but not chronic cough were associated with neonatal respiratory events (51;52). In our study, to address this issue most conservatively, recurrent wheezing and chronic cough will be measured as co-primary outcomes. Secondary analyses will consider these outcomes in combination.

The incidence of wheezing will be ascertained using the primary question used and validated in the Tucson Children's Respiratory Study (a large prospective birth cohort study of term infants) (53-59), "Has his/her chest ever sounded wheezy or whistling?" (53). Likewise, the incidence of cough will be ascertained using the Tucson question, "Has this child ever had a cough when he/she did not have a cold?" (53). As in Greenough's study, recurrent wheezing will be defined as episodes of wheezing occurring more than twice/week. Chronic cough will be defined similarly, cough occurring as more than twice/week. Additional questions will further characterize the wheezing and coughing episodes, including whether symptoms were associated with a viral illness (parental report of a "cold") or an environmental exposure. A symptom diary will be offered to study participants to help facilitate recall of pulmonary symptoms and need for outpatient pulmonary care.

The Tucson Children's Respiratory Study administered the questionnaires both in person and by phone, depending on patient availability. The investigators did not undertake a formal validation of phone vs. face-to-face administration of the questionnaire. Anecdotally, based on phone conversation with the study coordinator, investigators did not observe a difference in quality of responses between phone and questionnaires administered in person.

G.4.1.1 Standard Definition of Wheezing

Several studies have found that multiple colloquialisms in both English and Spanish can be used to describe wheezing (60-64), creating opportunity for misinterpretation of respiratory sounds and potential for over or under estimation of the incidence of wheezing. Other studies have found that clips of respiratory sounds played for families improve accuracy of symptom reporting (65;66), providing data relatively free from biases due to language, culture, literacy or interviewing techniques. To minimize misinterpretation of other respiratory sounds as wheezing, we will provide a verbal AND a brief audio clip that can be played for the interviewee at the beginning of the interview (electronic clip included separately). Accompanying the audio clip, wheezing will be defined verbally by the interviewer as an expiratory sound (a sound that is made when breathing out, not in) coming from the chest, sometimes described as whistling or musical. Although not yet widely used, use of audio clips to standard symptom definition is the best approach to bridge the language gap that exists between English and Spanish and among Spanish speaking populations using different dialects or colloquialisms.

In administering the questionnaires, every effort will be made to accurately measure the occurrence of pulmonary symptoms and health care and medication use, thus establishing the true incidence of pulmonary morbidity in the study population as a whole. Most importantly, however, because pulmonary morbidity is a blinded outcome of a randomized controlled trial, bias favoring one study arm over another should not occur.

G.4.1.2 *Parental Report for Non-English Speaking Populations*

Upon finalization of the questionnaires, Spanish language versions will be created and made available to all centers. The Cornell Translation Service, a University based professional translation service, will be contracted to perform the translation. For centers choosing to administer the questionnaires locally (Option 1), each center will be free to choose their primary interviewer who has the necessary skills. Administration of the questionnaire by a native speaker of the local Spanish dialect is recommended. For centers choosing Rochester to administer the questionnaire to their patients (Option 2), English and Spanish speaking individuals, trained to administer the questionnaires, will conduct the telephone or face to face interviews. An audio clip and verbal definition of wheezing will be presented to the respondent to standardize interpretation of wheezing and to minimize ascertainment biases due to language, culture, literacy or interviewing techniques.

G.4.1.3 *Parental Report of Pulmonary Symptoms Is a Reliable Outcome Measure of Airway Dysfunction*

Evaluation of frequency and severity of respiratory symptoms by parental questionnaire and need for pulmonary care has been used as the primary outcome in multiple follow up studies of term and premature infants (10;12;14;48). A recent review evaluated the value of respiratory symptom history ascertained by parental questionnaire in determining the risk for developing asthma in early childhood. By evaluating 9 large, longitudinal, full term birth cohort studies and reviewing the original questionnaire from 7 of these studies, Koopman found that the questions posed to parents eliciting a history of wheezing in their infants were similar. Parental report of wheezing predicted an increased risk for later respiratory symptoms, including asthma. In the studies proposed here, incidence of recurrent wheezing and chronic cough ascertained by parental report will be primary outcomes, rather than physiologic measurements of airway dysfunction, for several reasons.

G.4.1.4 *Reasons to Use Parental Report of Recurrent Wheezing and Chronic Cough as Primary Outcomes*

- Parental interview can be performed more readily on large numbers of patients. The validity of this approach has been shown in several longitudinal studies including The Tucson Respiratory Study.
- Recurrent wheezing is highly correlated with changes on pulmonary function testing (PFT). In infants with CLD, a history of wheezing was associated with greater expiratory flow limitation, hyperinflation and airway responsiveness to albuterol on PFT compared to those without such a history (24).
- Parental recall of respiratory illnesses has been shown to correlate strongly with review of medical office records. For asthma and bronchitis in the past year, Pless et al. found good agreement between recall of 288 parents and physician office chart review. Parental education and occupation were not predictive of a parent's ability to recall the illness (67). In an assessment of parental recall done to evaluate minor injury in children, Harel found recall declined with time, with the best recall occurring in the first 3 months after injury with further decline after 6 months from the time of the injury (47;68;69).
- Symptomatic airway dysfunction can be assessed in a standardized way. The NHLBI Consensus Expert Report developed standardized questions to assess severity of airway dysfunction. Three standardized questions from this report will be administered at 6, 12 and 18 months to assess symptom severity (70).

G.4.2 Definition Of Secondary Outcomes - Physician Diagnosed Wheezing. A secondary outcome will be parental report of physician diagnosed wheezing, defined as an episode of wheezing occurring at a health care visit. Physician diagnosed wheezing will be collected by parental report during the telephone or face to face interviews, using the question "Has your child been diagnosed with wheezing by a doctor?"

G.4.3 Definitions of Secondary Outcomes - Measures Need and Volume of Outpatient Pulmonary Care
Important secondary outcomes of outpatient pulmonary morbidity will be collected (Table 3).

Table 3. *Secondary Outcomes, Covariates and Sources*	
Outcomes	Source
Secondary Outcomes	
Number and duration of outpatient pulmonary medications including bronchodilator, diuretic, methylxanthine, and inhaled and systemic steroid therapy.	Family interview
Number of office visits for respiratory illnesses including pneumonia, bronchiolitis, asthma, bronchitis	Family interview
Number of emergency room visits for respiratory illnesses including pneumonia, bronchiolitis, asthma, bronchitis	Family interview
Number of re-hospitalizations for respiratory illnesses including pneumonia, bronchiolitis, asthma, bronchitis	Family interview
Growth at 18 months PMA (height, weight and head circumference)	NICHD follow up clinic data

G.4.4 Data Collection

Data collection for The Breathing Outcomes Study will be accomplished using one of two options (Figure 2, Table 2). Regardless of Option chosen, each local center will be responsible for obtaining informed consent and tracking patients following discharge.

Consent: For both options, every effort will be taken to enroll ALL SUPPORT patients into the Breathing Outcomes Study, including currently enrolled SUPPORT patients (both patients still in NICU and those discharged) and future enrollees. By obtaining pulmonary outcome data for both current and future SUPPORT patients, death or adverse pulmonary outcome can be analyzed as competing outcomes. Sample consent forms for currently enrolled and future SUPPORT patients are attached.

G.4.4.1 Data Collection: Ascertainment of Outcomes - Field Work

A. Ascertainment of Wheezing and Outpatient Pulmonary Morbidity By Interview.

There will be 4 parental interviews over 18-22 months, one face to face interview or telephone prior to or within 30 days of NICU discharge and 3 subsequent interviews (by telephone or face to face) at 6 month intervals to collect data on recurrent wheezing, chronic cough and volume of outpatient pulmonary care (Figure 1, A-D above). Based on review of longitudinal studies of full term infants in which follow up patient contacts occurred quarterly to once every 18 months', a 6 month interval for follow up patient contacts is planned in an effort to reduce parental recall omissions which are more likely to occur with less frequent follow up (48;68). The 4 interviews are designed to collect the primary and secondary outcomes of the follow-up study. Other inpatient and outpatient data will be collected as part of the NICHD Neonatal Network Generic Database (GDB) and Follow-up Program.

B. Interview Instruments – Questionnaires are based on the Tucson Children's Respiratory Study, a longitudinal cohort study that followed healthy term infants from birth to over 20 years of age. Questionnaires have been updated with validated symptom severity and tobacco smoke exposure questions, a current list of available respiratory medications and modifications that address health issues faced by formerly premature infants such as use of palivizumab for RSV prophylaxis. The original Tucson questionnaires are designed to elicit a thorough history of possible covariates, such as environmental and infectious exposures and family histories of atopy, asthma or respiratory disease.

C. Administration of Interview Instruments – Six, 12 and 18-22 month interviews will be initiated in one of two ways (table 2):

C.1 Option 1 - NICHD Network Center Follow Up Programs (local contact)

Individual NICHD Network Centers may choose to undertake administration and tracking of patients enrolled in the SUPPORT Breathing Outcomes Study. Local administration of the questionnaires capitalizes on existing NICHD resources available at local centers. Each Network Center choosing local administration of the telephone or face to face questionnaire will identify one or more interviewers who will undergo training in the administration of the questionnaire and tracking of enrolled patients. The Rochester Health Service Research Group will provide training and server as a resource to answer questions regarding administration of the questionnaire (outlined above).

Advantages of Conducting Telephone Interviews From the Local Network Centers

Conducting the telephone interviews from Local Centers will:
1) reduce risk for HIPPA violation
2) capitalize on existing rapport between the patient's family and their local center
3) avoid redundancy in making tracking calls to families

C.2 Option 2 - University of Rochester research staff (long distance contact)

The University of Rochester Neonatology Research Group has conducted similar telephone interview designs as part of an ophthalmologic outcome study of patients enrolled in a randomized trial of cryotherapy to treat ROP and a 15-year, longitudinal neurological assessment conducted by telephone survey among 132 infants treated with surfactant. Telephone follow up rates were 96% follow up at 7 years and 95% follow up at 15 years (71). In the study proposed here, the University of Rochester Health Services Research Group (HSR Group), will conduct the telephone interviews.

In telephone follow up surveys conducted by the HSR Group, follow up rates at 12 months' have exceed 75% in populations at high risk for being lost to follow up (72-78). Working with NICHD Network Centers to assist in tracking local families, follow up rates for this Follow-up Study are expected to exceed 80% and should approach the average annual NICHD follow up rate of 83%.

To facilitate tracking and record keeping, Network Centers choosing Rochester to administer questionnaires to their patients (table 2) will provide contract information to the Rochester site. RTI International will provide monthly updates of patients due for interviews. Local centers will be responsible to maintain updated contact information. Each interview will close with a question as to whether the family plans a new address or phone number prior to the next interview. The names and phone number of a friend or relative will be sought so that they may be contacted in the event that contact with the patient is lost. If contact information is updated, the new contact information will be transmitted back to the local center. By interviewing families every 6 months, a higher follow up rate will be achieved because family contact information will not become so out of date that the family is lost or that re-contacting them is inefficient. We anticipate that each interview will require 2 hours of staff time, with 20-30 minutes to conduct the interview and 90 minutes to contact family and enter data.

Advantages of Conducting Telephone Interviews From a Central Research Facility

Conducting the telephone interviews from Rochester will:
1) require less effort from the individual Network Centers
2) allow standardization of the telephone interview by a core group of trained interviewers
3) blind the telephone interviewer to the SUPPORT Trial study group designation
4) reduce the cost of the study by consolidating the telephone training and follow up at one site.

G.4.4.2 Data Collection: Ascertainment of Environmental and Genetic Covariates

Ascertainment of important environmental exposures and genetic risk factors that might confound the relationship between supplemental oxygen exposure and symptomatic airway dysfunction will be obtained along with the primary outcomes during the same interviews (Table 4). Tobacco smoke exposure is a potentially significant risk factor for airway dysfunction. The tobacco smoke question in the Tucson Study has been replaced by a question shown by Dr. Wakefield et al to correlate with cotinine levels in infants (79;80).

Table 4. Postnatal and Genetic Covariates Evaluated as Potential Confounders of Oxygen and Wheezing

Covariates in Home Environment and Exposures The initial questionnaire and 6 month interviews will gather information on other *inhaled exposures* (tobacco, wood stoves, cold air), *residence* (crowding, siblings, daycare), *infectious exposures* (RSV, palivizumab) and medical risk factors (congenital anatomic airway abnormalities)

Covariates in Family History Questionnaires will elicit *family history* of atopy (family history of asthma, eczema or allergy to foods, pets).

G.4.4.3 Data Collection: Ascertainment of Primary Exposure

Oxygen Exposure

In the SUPPORT Trial, it is assumed that managing infants with a higher vs. lower targeted oxygen saturation range will result in different levels of supplemental oxygen exposure. The SUPPORT Trial will collect data on FIO2 exposure to quantify the anticipated difference. As part of the SUPPORT Trial, FIO2 values will be recorded and analyzed at many time points including time of admission, first blood gas, and as described in the SUPPORT Manual of Operations, Chapter 10 Safety Monitoring Form. Because oxygen is the primary exposure in the SUPPORT Breathing Oucomes Study and plays a central role in the disease model proposed, oxygen exposure will be quantified as described in the main SUPPORT trial and analyzed as a predictor of later symptomatic airway dysfunction.

G.5 Sample size estimate with some statistical support based upon primary outcome

G.5.1 Sample Size

The SUPPORT Trial anticipates enrollment of 1310 patients $\geq 24^{0/7}$ and $\leq 27^{6/7}$ weeks' gestation, providing 80% power to detect a 10% difference between treatment groups in the incidence of death/CLD and death/stage III Retinopathy of Prematurity (ROP). Assuming mortality of 22% for infants in this GA range (NICHD 2001-2002 data), 1021 infants would be expected to survive and be eligible for the SUPPORT Breathing Outcomes study.

Power for detecting a difference between the high vs. low saturation groups for the primary outcome

First we consider power for detecting a difference between the high and low saturation groups for the first primary outcome, recurrent wheezing. We expect the incidence of wheezing to be about 0.17 in the low saturation group and about 0.31 in the high saturation group (12). For the power calculations, we also consider a scenario with a smaller difference between groups: 0.19 for the low saturation group and 0.29 for the high saturation group. We expect the follow up rate to be about 80% (NICHD historical average follow up rate), which would result in data on about 816 patients. We also consider a lower follow up rate of 65%, which would result in about 663 patients. Power to detect a difference between groups based on a chi-square test with type I error alpha set at 0.05 is given in Table 5 for each scenario. From those results, we expect to have more than 80% power for the primary outcome. Also of interest are subgroup analyses, where we look separately at the CLD and non-CLD subjects. Of survivors, we expect 37% or 378 infants to have CLD. For the CLD group, we expect the incidence of wheezing to be about 0.5 in the high saturation group and 0.3 in the low saturation group. If there is a 80% follow up rate, we will have 95% power to detect a difference between the two groups. For the non-CLD subgroup, we expect the incidence to be 0.2 and 0.1 in the high and low groups, respectively. With 80% follow up, we will have 92% power. Thus, we expect to have adequate power for the primary outcome even in the analyses stratified by CLD.

Table 5. Power for primary outcome.

Follow-up rate	Low Saturation	High Saturation	power
80%	0.17	0.31	0.99
80%	0.19	0.29	0.90
65%	0.17	0.31	0.98
65%	0.19	0.29	0.83

Power for detecting a difference between the high vs. low saturation groups for secondary outcomes

We expect the study to be adequately powered for analysis of important secondary outcomes such as use of pulmonary medications. Based on results reported in Davis et al. for infants less than 27 weeks' gestational age [22], we expect the rate of pulmonary medication use to be 0.42 in the high saturation group and 0.19 in the lower saturation group. In that case, even with a 65% follow up rate, we would have more than 99% power to detect a difference between the groups with a chi-square test. Similarly, the CLD subgroup analyses would have more than 80% power under those assumptions. Based on the power numbers above, we could potentially enroll fewer subjects in the trial and still have adequate power. However, we choose to over enroll slightly to make up for the fact that some patients will likely be lost to follow up. The recruitment time will be that of the SUPPORT Trial (2 years) with a run out period of 18-22 months to ascertain follow-up outcomes. The total study period is 36-40 months.

G.5.2 Data Analysis

Analysis of primary dichotomous outcomes will be performed by chi square test and presented as a relative risk for development of that outcome. Number of outpatient pulmonary visits for respiratory illnesses will be presented as median values. The Wilcoxon Rank Sum test, a non-parametric alternative to the two-sample t-test, will be used to test for differences between the two groups. Statistical analyses will need to consider the effect of multiple comparison groups on the level of statistical significance. All analyses will be performed in conjunction with the Research Triangle Institute (RTI, North Carolina). Data will be presented as shown in tables 6-7. Mean FIO2 values in the high and low SpO2 groups will be compared by two sample t-test. Analyses will be done to evaluate the effect of ventilator strategy on pulmonary outcome and presented similarly to table 6 and 7. Other secondary analyses will be performed, including analyses of respiratory outcomes by presence or absence of CLD (oxygen at 36 weeks' PMA determined by SUPPORT study criteria). The incidence of outpatient respiratory diagnoses, such as asthma or reactive airway disease, will be compared between intervention groups and, in sub group analyses, between intervention groups by presence or absence of CLD.

Table 6. *Primary Dichotomous Outcomes*	**Low Saturation**	**High Saturation**	**RR**	**CI**	**p-value**
Parental Report of Recurrent Wheezing (%)					
Parental Report of Chronic Cough (%)					
Need for Outpatient Pulmonary Medications (%)					
Need for Physician Visit for Respiratory Illness (%)					
Need for Re-hospitalization for Respiratory Illness (%)					

Table 7. *Primary Outcomes – Continuous Outcomes*	**Low Saturation**	**High Saturation**	**p-value**
Number of Physician Visit for Respiratory Illness (Median)			
Number of Emergency Visits for Respiratory Illness (Median)			
Number of Re-hospitalization for Respiratory Illness (Median)			

G.5.2 Expected Results

We predict that premature infants managed with a lower targeted oxygen saturation range compared to those managed with a higher targeted oxygen saturation are exposed to lower levels of supplemental oxygen and have reduced risk of recurrent wheezing in the first 18-22 months' CA.

G.5.2 Anticipated Problems and Solutions

1) Participant attrition. As seen in the sample size calculation, the potential for patients to be lost to follow up over time will be offset by over enrolling patients to participate in the follow up. Because patients who enroll in the SUPPORT Trial are randomized, there should be no systematic bias favoring one group over another among patients who are lost to follow up. However, if loss to follow up is in part caused by the treatment or outcomes, this could bias the results. We will therefore investigate whether there are differences in key variables for subjects who are lost to follow up compared to those who remain in the study. For example, we will test whether subjects in one treatment arm were more likely to be lost to follow up than in the other arm. Similarly, we will compare wheezing rates at 6 months' for those who are later lost to follow up compared to those who remain in the study. We do not expect to see any major differences.

2) Difficulty tracking families. With mobile families, keeping contact information up to date may be difficult. To promote successful follow up in both the Breathing Outcome Study described here and the routine NICHD neurodevelopmental follow up visit at 18 - 22 months, each center will be responsible to track families to maintain current contact information for both the family and primary care physician.

3) Center variability in administering the questionnaire. With 11 centers administering the questionnaires, variation in techniques and styles in administering the questionnaires has the potential to introduce ascertainment bias. To minimize this risk, staff administering the questionnaires will undergo an interviewer training program conducted by the Rochester Site. The program will consist of a conference call and a practice interview of a standardized patient.

4) The SUPPORT Breathing Outcomes Study has been prepared as the central project for Dr. Stevens' Patient Oriented Clinical Research Grant (K23 Award), revised submission 7/1/05. If approved, funds from the K23 will be available to offset a portion of the cost of conducting this Follow-up Study. If not approved, NICHD funding has been approved to support the project.

5) Initiation of the Breathing Outcomes Study after enrollment into SPPORT has begun.

5.1 Babies already enrolled in SUPPORT

To help assure pulmonary outcome assessment for all SUPPORT patients, families of babies already enrolled in SUPPORT will be approached with a separate consent to enroll in the Breathing Outcomes Study. IRB approval of this consent form will be required.

5.2 *Future babies eligible for enrollment in SUPPORT*

Going forward, a modified SUPPORT Consent Form, which includes consent for the Breathing Outcomes Study, will be need to be prepared at each center. **The revised SUPPORT Consent will require**

G.6 Available population/compatibility with other ongoing protocols

Another secondary study proposed by a group independent from ours is looking at the genetics of reactive airways disease in patients enrolled in the SUPPORT Trial. The follow on study proposed here should be complementary to the genetics study, enhancing the both the quality and quantity of data on the prevalence of wheezing and need for outpatient pulmonary care in patients enrolled in the SUPPORT Trial.

G.7 Estimate of projected recruitment time

The recruitment time will be that of the SUPPORT Trial with a 18-22 month period of follow up to ascertain primary and secondary outcomes.

H. RISKS / BENEFITS, WITH ESTIMATE OF FREQUENCY / SEVERITY OF RISKS.

By using clinical measures of outpatient pulmonary morbidity, the effect of NICU based respiratory interventions on respiratory health and need for outpatient medical care may be quantified, allowing assessment of whether infants who develop CLD and those who do not have improved pulmonary health as a result of the study intervention. In addition to creating a potential model for outpatient pulmonary follow up, the proposed follow on study may improve follow up at the 18-22 month NICHD visit by maintaining contact with families during the interval between NICU discharge and the follow up visit. We anticipate no risk to the patient of this observational follow on study.

NICHD SUPPORT Trial
Breathing Outcomes Study

NICU Discharge-Baseline Interview

This interview should be administered by trained study staff to the parent/guardian. The target window for this interview is prior to NICU discharge or within the first 30 days following NICU discharge. For patients enrolled in the Pulmonary Outcomes Follow up Study after this target window, this interview should be performed at the time of enrollment.

This interview is for:

_____
(Child's name)

All questions pertain only to his/her health.

N.B. Parents or guardians expressing concerns regarding their child's breathing should be advised to discuss them with the family's primary care physician.

Introduction to the Study:
Premature babies are more likely than full term babies to have breathing problems after discharge from the NICU. The purpose of this study is to see whether or not the treatment your baby received as part of the SUPPORT Study improves your baby's breathing in the 18-22 months following the baby's due date.

As part of this study, we will contact you every 6 months or so to ask you questions about your baby's breathing. The questions will be about your baby's breathing symptoms, especially wheezing and coughing, and about your baby's need for medical visits and treatments for breathing problems.

Wheezing can mean different sounds to different people. By wheezing we mean an expiratory sound (a sound that is made when breathing out, not in) that comes from the chest, sometimes described as whistling or musical.

We have prepared a brochure for you that describes the study and outlines important characteristics of your baby's breathing, especially breathing problems and treatments.

Give brochure

When we call, we'd like you to gather any notes, medications or other information about your baby's breathing. We will ask questions about how often your baby has wheezing or coughing, whether your baby visited a doctor's office, emergency room or was hospitalized for breathing problems, and whether your baby has needed breathing medicines or treatments. If you wish, you may use the brochure to make notes about your baby's breathing.

In order to help us understand your baby's breathing and risk for breathing problems at home, we'd like to ask you a few questions about your home and about whether breathing problems run in the family. As with all information we collect, the answers to these questions will be kept confidential.

NICU Network	SUPPORT TRIAL Breathing Outcomes Study	SUPF01 Rel 1.0 October 12, 2005

NICU Discharge-Baseline Interview

Center: ___ Site: ___ Network No. _____ SUPPORT Follow-up No. _____ Birth No. ___ Mother's Initials: ____

1. Child's Name_____ _____ (first) (last) 2.Today's Date: |__|__| - |__|__| - |__|__|__|__| mm dd yyyy

3. Child's Sex: 1~ Male 2~ Female

4. Child's Birthdate: |__|__| - |__|__| - |__|__|__|__| mm dd yyyy

Enter name and relationship code of the person being interviewed.

5a. Name: _____ _____ 5b. Relationship Code: |__|__|__|

001 - Mother of Child
002 - Father of Child
301 - Adoptive mother
302 - Adoptive father

Other: _____
Common codes are listed here. For other relationships, please look up relationship code from Appendix B of the Follow up Manual of Procedures and enter above.

6. Type of Interview: 1~ Face to Face 2~ Telephone

At this time, we would like a little information about the environment in which your new child will grow up.

7. First, how many people normally live with you in your home for at least 6 months of the year?

Total household members: |__|__|

8. After the first few months, will your child be sharing a room with other family members on a regular basis?

1~ Yes 2~ No

8a. IF YES: How many people will sleep in the same room with him/her? |__|__|

9. How many rooms are there in your house, excluding closets and bathrooms? |__|__|

10. Do you have any pets inside the home? 1~ Yes 2~ No *Skip to Question 11*
If YES, how many.....
10a. *check and record number:* 1~ Dogs in the home? |__|__|
2~ Cats in the home? |__|__|
3~ Other pets are in the home? |__|__| SPECIFY: _____

11. Does your home or apartment have air conditioning or some kind of cooling? 1~ Yes 2~ No *Skip to Question 12*
If YES,
11a. Air Conditioning? 1~ Yes 2~ No
11b. Evaporative Cooling? *(Desert Southwest)* 1~ Yes 2~ No
11c. Other? 1~ Yes 2~ No If YES, SPECIFY_____

12. How is your home heated? (IF MORE THAN ONE, PLEASE CHECK ALL THAT APPLY).
    1~ Steam or hot water (radiator)
    2~ Central gas furnace (furnace)
    3~ Electric
    4~ Wood Stove
    5~ Other SPECIFY: _____
    6~ Don't know

13. What one fuel is used most for cooking in your home?
    1~ Electricity
    2~ Gas
    3~ Fuel Oil
    4~ Wood Stove
    5~ Other SPECIFY: _____
    6~ Don't Know

The next questions are about your baby's diet.

14. Is your child receiving: (READ ALL CHOICES)
    1~ Only breast milk
    2~ Only formula *Skip to Question 15*
    3~ Both breast milk and formula *Skip to Question 15*

If answer to 14 is 1 (only breast milk)

a. Will this be supplemented with formula in the first 6 months?

1~ Yes 2~ No 3~ Don't Know

b. If yes, when will supplements begin? |___|___| months

15. Does the mother (you) plan to work outside the home within the next year?
    1~ Yes
    2~ No
    3~ Don't Know

The next questions are about smoke exposure.

16. Which one of the following 3 statements best describes the situation regarding smoking in your child's **home**? *Read all options to the interviewee before recording a response.*

1❑ Smoking is allowed in any common room of the home
2❑ Smoking is limited to part of the house where the child rarely goes
3❑ There is no smoking inside at all → 16a. Are there any exceptions to this situation?

1~ Yes 2~ No (Skip to Question 17)

16b. Under what circumstances are the exceptions allowed? SPECIFY:

_____

17. Which one of the following 5 statements best describes the situation regarding smoking in your **car**? *Read all options to the interviewee before recording a response.*
    1❑ Do not have a car
    2❑ Smoking is usually or always allowed
    3❑ Smoking is sometimes allowed
    4❑ Smoking occurs in the car only when the child is not inside
    5❑ There is no smoking inside the car → 17a. Are there any exceptions to this situation?

1~ Yes 2~ No (Skip to Question 18)

17b. Under what circumstances are the exceptions allowed? SPECIFY:

_____

18. How often has the baby's mother or primary caretaker (you) smoked since your child was born?

1~ Never 2~ Occasionally 3~ Daily

19. Altogether, how many people who live in the child's home smoke? |__|__| people

In the next section, we'd like to know what breathing and allergy problems run in the family. Administer attached Family History Questionnaire using the following script:

Mother or guardian:

We'll start with the baby's mother. How old is the baby's biologic mother? Does she have bronchitis, emphysema, COPD, bronchiectasis, asthma, inhaled allergies, or food allergies?

Does the baby's mother have any other chronic respiratory illness?

How often does this person smoke in the baby's home?

Father
For the baby's biologic father, is he living? How old is he? Does he have bronchitis, emphysema, COPD, bronchiectasis, asthma, inhaled allergies, or food allergies?

Does he have any other chronic respiratory illness?

How often does he smoke in the baby's home?

Complete the remainder of the table by collecting the same medical history using the scripting above.

20. Finally, which friend or relative is most likely to be able to contact you 6 months from now in case we lose contact with you?

_____ _____
Name Relationship

_____
Address

_____
Telephone

_____
Cell Phone

_____
Email

Thank you for your help in providing us with this important information, and for your continued participation in the Breathing Outcomes Study.

Never = never; rarely = less than once per month; sometimes = once per month but less than once /week; frequently = once per week or greater
DK = Don't Know

NICHD SUPPORT Trial
Breathing Outcomes Study

Administered At 6 And 12 Months Corrected Age

This interview should be administered by a trained study interviewer for:

_____
(Child's name)

All questions pertain only to his/her health.

The parent or care giver, who completed the initial interview, should complete this survey and all future surveys. The interviewer will need to ask for that parent (see Manual of Operations).

Introduction Script:
When parent or primary care giver is on phone:

Hello, my name is <your name>. I am calling from the <NICHD Center>. As you probably remember, when you were in the NICU you enrolled in our study about respiratory health of premature infants. I am calling to ask you some questions about your baby's breathing. It will take about 10-20 minutes to complete. Is this a good time for you?

As with all information we collect, the answers to these questions will be kept confidential.

Before we begin this interview, it would be helpful if you could gather any notes you have about your baby's breathing as well as any medications your child has been prescribed or has been taking and have them in front of you. As with all information we collect, the answers to these questions will be kept confidential.

Center: ____ Site: ___ Network No. _____ SUPPORT Follow-up No. _____ Birth No. ___ Mother's Initials: _____

Instructions:
Parents or guardians expressing concerns regarding their child's breathing should be advised to discuss them with the family's primary care physician.

Where the phrase "last contact" is used below, please substitute with the most specific relevant time prompt, e.g. for the 6 month interview, refer to "since NICU discharge"; for the 12 month interview, refer to "over the past 6 months", etc.

Interview begins:
Some of these questions will be familiar to you. Since we last spoke (__ __) months ago on (__ __/__ __/__ __) we want to learn what changes, if any, there have been to your child's health. We are especially interested in any breathing problems your child may have.

5. Has the child been with you during the past 6 months? 1~ Yes 2~ No

Since our last contact with you about your child.....

6. How many times has your child visited a doctor's office? |___|___| times

6a. How many of these times were because of wheezing or breathing problems? |___|___| times

Since our last contact with you about your child.....

7. How many times has your child visited an Emergency Department (Emergency room)? |___|___| times

7a. How many of these times were because of wheezing or breathing problems? |___|___| times

Since our last contact with you about your child.....

8. How many times has your child stayed in the hospital for one or more nights in a row? |___|___| times

8a. How many of these times were because of wheezing or breathing problems? |___|___| times

The next questions are about your baby's breathing.
The first question is about wheezing. By wheezing we mean an expiratory sound (a sound that is made when breathing out, not in) that comes from the chest, sometimes described as whistling or musical.

9. Since our last contact with you, has your baby's chest sounded wheezy or whistling?

1~ Yes 2~ No 3~ Don't know

Question 9a. "Has your baby's breathing sounded like this?" ***(play audio clip of wheezing).***

1~ Yes 2~ No 3~ Don't know If 2 or 3, SKIP TO QUESTION 10

IF **YES** TO QUESTION 9 or 9a:

9b. Has this occurred with colds?
1~ Yes
2~ No *Skip to c*
3~ Sometimes

9c. Has your child's chest sounded wheezy or whistling apart from colds?
1~ Yes
2~ No

9d. During what month did your child's chest first sound wheezy or whistling?

|___|___|months (enter calendar month, Jan = 01; Feb = 02); |___|___| Year

9e. Since our last contact with you, **on average**, how often has your child's chest sounded wheezy or whistling during:

The Daytime? Would you say...(e.1)	***The Nighttime? Would you say...(e.2)***
1❑ Never	1❑ Never
2❑ Twice a week	2❑ Once every two weeks or less
3❑ More than two times a week, but not every day	3❑ Once a week
4❑ Everyday, but *not* all the time	4❑ More than 1 night a week
5❑ Everyday, all the time	5❑ Frequently/Every night

9f. Since our last contact with you, **during the worst 2 week period**, how often has your child's chest sounded wheezy or whistling during:

The Daytime? Would you say... (f.1)	***The Nighttime? Would you say...(f.2)***
1❑ Never	1❑ Never
2❑ Twice a week	2❑ Once every two weeks or less
3❑ More than two times a week, but not every day	3❑ Once a week
4❑ Everyday, but *not* all the time	4❑ More than 1 night a week
5❑ Everyday, all the time	5❑ Frequently/Every night

9g. Since our last contact with you, has your child been diagnosed with wheezing by a doctor?
1~ Yes
2~ No

IF YES, BE SURE TO COMPLETE QUESTION 27

10. Since our last contact with you, has your child had a cough for more than 3 days when he/she did not have a cold?

1~ Yes 2~ No SKIP TO QUESTION 11

IF **YES** TO QUESTION 10

10a. At what time of the day has this cough usually occurred? (CHECK ALL THAT APPLY)

1~ In the morning, shortly after rising
2~ Later in the day
3~ During the night
4~ No relation to time of day

10b. Has he/she coughed on most days for as much as 2 to 3 months?

1~ Yes
2~ No

10c. During what month and year did your child first develop the cough?

|___|___|months (enter calendar month, Jan = 01; Feb = 02); |___|___| Year

10d. Has your child's chest ever sounded wheezy or whistling with episodes of coughing?

1~ Yes
2~ No

10e. Since our last contact with you, **on average**, how often has your child had coughing during:

The Daytime? Would you say... (e.1)	***The Nighttime? Would you say...(e.2)***
1❑ Never	1❑ Never
2❑ Twice a week	2❑ Once every two weeks or less
3❑ More than two times a week, but not every day	3❑ Once a week
4❑ Everyday, but *not* all the time	4❑ More than 1 night a week
5❑ Everyday, all the time	5❑ Frequently/Every night

10f. Since our last contact with you, **during the worst 2-week period**, how often has your child had coughing?

The Daytime? Would you say... (f.1)	***The Nighttime? Would you say...(f.2)***
1❑ Never	1❑ Never
2❑ Twice a week	2❑ Once every two weeks or less
3❑ More than two times a week, but not every day	3❑ Once a week
4❑ Everyday, but *not* all the time	4❑ More than 1 night a week
5❑ Everyday, all the time	5❑ Frequently/Every night

11. Since our last contact with you, **on average**, how many **days per month** did you have to change your daytime or evening plans because of your child's breathing problems:

1❑ None, we never had to change plans
2❑ More than none but less than 3 days
3❑ 3-6 days
4❑ 7 or more days

12. Since our last contact with you, **during the worst 2 week period**, how many **days** did you have to change your daytime or evening plans because of your child's breathing problems:

1❑ None, we never had to change plans
2❑ More than none but less than 3 days
3❑ 3-6 days
4❑ 7 or more days

13. Since our last contact with you, has your child had asthma, reactive airways disease or a BPD flare-up diagnosed by a doctor? 1~ Yes 2~ No

14. Since our last contact with you, has your child had bronchiolitis, bronchitis, or pneumonia diagnosed by a doctor?

1~ Yes 2~ No

15. Since our last contact with you, has your child had croup diagnosed by a doctor?
1~ Yes 2~ No

The next questions are about your baby's diet.

16. Since our last contact with you, did your baby receive mother's breast milk, either at breast, from a bottle or through a tube?

1~ Yes 2~ No If NO, skip to Question 17

If yes to Question 16:

16a. For how many months did your child receive breast milk feedings?
Would you say... 1~ Less than 1 month
2~ 1-3 months
3~ 4-6 months

16b. For how many months did your child receive breast milk for more than half of his/her feedings?
Would you say... 1~ Less than 1 month
2~ 1-3 months
3~ 4-6 months

The next questions are about smoke exposure.

17. Which one of the following 3 statements best describes the situation regarding smoking in your child's **home**? *Read all options to the interviewee before recording a response.*
1❑ Smoking is allowed in any common room of the home
2❑ Smoking is limited to part of the house where the child rarely goes
3❑ There is no smoking inside at all → 17a. Are there any exceptions to this situation?

1~ Yes 2~ No (Skip to Question 18)

17b. Under what circumstances are the exceptions allowed? SPECIFY:

_____

18. Which one of the following 5 statements best describe the situation regarding smoking in your **car**? *Read all options to the interviewee before recording a response.*
1❑ Do not have a car
2❑ Smoking is usually or always allowed
3❑ Smoking is sometimes allowed
4❑ Smoking occurs in the car only when the child is not inside
5❑ There is no smoking inside the car → 18a. Are there any exceptions to this situation?

1~ Yes 2~ No (Skip to Question 19)

18b. Under what circumstances are the exceptions allowed? SPECIFY:

_____

19. How often has the **mother or primary care giver** smoked since your child was born?

1~ Never 2~ Occasionally 3~ Daily

20. How many people in the child's home smoke? |___|___| people

The next questions are about your home and your babysitter's home or day care.

21. Approximately how many hours per week does your child spend at a babysitter's home or day care?
|___|___| hrs *If 0, skip to Question 22*

IF 21 is greater than 0:

21a. How frequent is there smoke exposure at the babysitter or daycare?
1~ Never 2~ Occasionally 3~ Daily 4~ Don't Know

21b. How many children beside your baby are in the daycare? | | | | children

22. How many children under 12 live in your house? |__|__| children

23. Do you have any pets inside the home? 1~ Yes 2~ No *Skip to Question 24*

23a. If YES, how many pets are there inside the home?
Check all that apply and record number: 1~ Dogs |__|__|
2~ Cats |__|__|
3~ Other |__|__| SPECIFY: _____

The last questions involve respiratory treatments that your baby may receive.

PROPHYLAXIS

24. Has your child had RSV shots to prevent Respiratory Syncytial Virus (Synagis, palivizumab, RSV shot)?

1~ Yes 2~ No 3~ Don't know

25. Has your child had a flu shot? 1~ Yes 2~ No 3~ Don't know

OXYGEN

26. Is your child on any oxygen therapy at home?

1~ Yes 2~ No Skip to Question 27

Indicate Yes or No for each			*lpm = liters per minute
26a. Oxygen cannula	1~ Yes	2~ No FiO2_____	lpm*_____
26b. Oxygen hood	1~ Yes	2~ No FiO2_____	lpm*_____
26c. Ventilator	1~ Yes	2~ No FiO2_____	lpm*_____

MEDICATIONS *(Enter responses in table. Do not prompt for each medication in the Medication Code List below.)*

The last two questions involve the medicines your child is taking for breathing problems.

27. Since our last contact with you, what medicines has your baby taken, including medicines delivered by a nebulizer or breathing machine at home?	27a. Code	27b. Does he/she take that medicine everyday, sometimes or only when sick? *(repeat for each medication)*
1		1❑ Everyday 2❑ Sometimes 3❑ Only when Sick
2		1❑ Everyday 2❑ Sometimes 3❑ Only when Sick
3		1❑ Everyday 2❑ Sometimes 3❑ Only when Sick
4		1❑ Everyday 2❑ Sometimes 3❑ Only when Sick
5		1❑ Everyday 2❑ Sometimes 3❑ Only when Sick
6		1❑ Everyday 2❑ Sometimes 3❑ Only when Sick
7		1❑ Everyday 2❑ Sometimes 3❑ Only when Sick

Medication Code List:

Rescue medicines:
1 Albuterol
2 Proventil
3 Serevent
4 Ventolin
5 Volmax
6 Xopenex

Other Inhaled medications:
7 Cromolyn (Intal)
8 Nedocromil (Tilade)

Inhaled steroids:
9 Advair
10 Aerobid
11 Azmacort
12 Beclovent
13 Flovent
14 Vanceril
15 Pulmicort

Systemic steroids:
16 Decadron
17 Prednisone
18 Prednisolone

Leukotriene blocker:
19 Accolate
20 Singulair

Methylxanthines:
21 Theophylline

Diuretic medications:
22 Diuril
23 Lasix
24 Aldactizide
25 Aldactone

Miscellaneous / Non-specific
26 Nebulizer
27 Other_____

Thank you for your cooperation in providing us with this important information, and for your continued participation in the Breathing Outcomes Study.

NICHD SUPPORT Trial
Breathing Outcomes Study

Administered At 18-22 Months Corrected Age

This interview should be administered by a trained study interviewer. The target window for this interview is between 18-22 months' corrected age.

_____
(Child's name)

All questions pertain only to his/her health.

Introduction Script:
When parent or primary care giver is on phone:

Hello, my name is <your name>. I am calling from the <NICHD Center>. As you probably remember, when you were in the NICU you enrolled in our study about respiratory health of premature infants. I am calling to ask you some questions about your baby's breathing. It will take about 10-20 minutes to complete. Is this a good time for you?

As with all information we collect, the answers to these questions will be kept confidential.

Before we begin this interview, it would be helpful if you could gather any notes you have about your baby's breathing as well as any medications your child has been prescribed or has been taking and have them in front of you.

Formatted: Bullets and Numbering

The next 2 questions are about respiratory infections.....

28. **During the past year**, for how many days has your child been unable to do his/her usual activities because of illnesses such as chest (not head) colds, bronchitis, asthma or pneumonia?
   1❑ 0-3 per year
   2❑ 4-5 per year
   3❑ 6-9 per year
   4❑ more than 9 per year

29. **During the past year**, how many head colds (common colds) has your child had? Would you say...
   1❑ 0-3 per year
   2❑ 4-5 per year
   3❑ 6-9 per year
   4❑ more than 9 per year

The last questions are about allergies.

30. Has your child **ever** had hay fever or any other condition that makes his/her nose runny, stuffy, or itchy **apart** from colds? 1~ Yes 2~ No

31. Has your child **ever** had allergies which cause nose, eye or lung problems?
   1~ Yes 2~ No

32. Has your child **ever** been allergic to any food?
   1~ Yes 2~ No

33. Has he/she **ever** been allergic to any medicine?
   1~ Yes 2~ No

34. Has your child **ever** had eczema (allergic skin rash)?

1~ Yes 2~ No (End of Interview)

34a. Was eczema diagnosed by a doctor?

1~ Yes 2~ No

End of Interview

Manual of Operations

~~November 1, 2005~~November 3, 2005

TABLE OF CONTENTS

Chapter 1
Overview and Trial Design

1.1 Introduction

This manual provides detailed instructions of study procedures for the Breathing Outcomes~~Follow-up~~ Study of the NICHD SUPPORT Trial ~~Pulmonary Outcomes Follow-up Study~~ (The SUrfactant Positive Airway Pressure and Pulse Oximetry Trial in Extremely Low Birth Weight Infants). This manual should be used as a reference guide for study staff including investigators, coordinators, and data managers. The trial objectives and design are summarized briefly below. For further discussion to the study background and design, please refer to the Breathing Outcomes~~Follow-up~~ Study Protocol.

1.2 Study Design

This study is a longitudinal follow-up of surviving infants enrolled, randomized and treated as part of the SUPPORT Trial, which was a prospective, randomized, factorial 2X2 design multi-center trial conducted by the NICHD Neonatal Research Network. This follow-up study will determine the effect of lower targeted oxygen saturation ranges and more aggressive use of CPAP on the incidence of symptomatic airway dysfunction (defined as recurrent wheezing or chronic cough) and volume of outpatient care in the first 18-22 months' corrected age (CA). The individual factors to be tested in this follow-up study are:

1) Symptomatic airway dysfunction and need for outpatient pulmonary care in the first 18-22 months among infants managed with a lower SpO2 range (85% to 89%) as compared to a higher, more conventional SpO2 range (91% to 95%).

2) Symptomatic airway dysfunction and need for outpatient pulmonary care in the first 18-22 months corrected age among infants managed with CPAP and a permissive ventilatory strategy versus infants managed with prophylactic surfactant and conventional ventilation begun in the delivery room and continuing in the NICU.

Table 1 below describes the study treatment groups. Refer to the SUPPORT Trial Protocol for further details regarding the projected outcomes relative to the study interventions

Table 1: SUPPORT Trial Study Treatment Groups

Randomized Intervention	**Low SpO2 85% to 89%**	**High SpO2 91 to 95%**
Treatment **Early CPAP**	Early CPAP + Low SpO2	Early CPAP + High SpO2
Control **Prophylactic/Early Surfactant**	Control + Low SpO2	Control + High SpO2

1.3 Primary Hypotheses

1) We hypothesize that relative to infants managed with a higher SpO2 range (91% to 95%),

infants managed with a lower SpO2 range (85% to 89%) will have less frequent episodes of symptomatic airway dysfunction and reduced need for outpatient pulmonary care at 18-22 months' CA.

2) We hypothesize that relative to infants managed with prophylactic surfactant and conventional ventilation, infants managed with early CPAP and permissive ventilator strategy will have less frequent episodes of symptomatic airway dysfunction and reduced need for outpatient pulmonary care in the first 18-22 months' CA.

1.4 Secondary Hypotheses

1) We hypothesize that **among infants with CLD**, infants managed with a lower SpO2 range relative to those managed with a higher SpO2 target range and infants managed with early CPAP and permissive ventilator strategy compared with those managed with prophylactic surfactant and conventional ventilation will have less frequent episodes of symptomatic airway dysfunction and reduced need for outpatient pulmonary care during the first 18-22 months' CA.

2) We hypothesize that **among infants without CLD**, infants managed with a lower SpO2 range relative to those managed with a higher SpO2 target range and infants managed with early CPAP and permissive ventilator strategy compared with those managed with prophylactic surfactant and conventional ventilation will have less frequent episodes of symptomatic airway dysfunction and reduced need for outpatient pulmonary care during the first 18-22 months' CA.

1.5 Summary of Data Forms

The following is a summary of the data forms used in this study. Further details on each form are provided in subsequent chapters. A complete set of forms can be found in Appendix A.

NICU Discharge-Baseline Interview (SUPF01)
This interview will be administered to the parent or guardian by trained study ~~staff~~ staff prior to NICU discharge or within 30 days after NICU discharge. For patients enrolled into the Breathing Outcomes Study after NICU discharge, this questionnaire can be administered prior to the 6 month questionnaire. Questions concerning family medical history, anticipated living arrangements, and alternate contact information will be asked.

The purpose of the discharge questionnaire is to assure adequate randomization of important covariates affecting outpatient respiratory health and to obtain baseline data on home environment and family history of respiratory diseases.

6 Month and 12 Month Interview (SUPF02)
This interview will be administered by telephone or face to face to the parent or guardian by a trained ~~telephone~~ interviewer at 6 months' CA and again at 12 months' CA.

The purpose of these questionnaires is to obtain an **interval** respiratory history. Questions are designed to collect respiratory history since the last contact with the interviewee, such that when the 6, 12 and 18-22 month questionnaires are taken together, a complete respiratory history over the time period is collected.

18-22 Month Interview (SUPF03)

This interview will be administered to the parent or guardian at 18-22 months CA by either telephone interview prior to the regularly scheduled 18-22 month NICHD developmental follow up clinic visit or face to face at the time of the visit.

The purpose of these questionnaires is to obtain an **interval** respiratory history and to identify environmental exposures that may increase the likelihood of symptomatic airway dysfunction.

Chapter 2
Administration

2.1 Organizational Structure

The NICHD Neonatal Research Network is conducting this study. The Network is funded by the NICHD under cooperative agreements with seventeen institutions comprised of sixteen clinical centers and a data coordinating center. The Steering Committee for the Network consists of the Principal Investigator from each clinical center, the data center, and the NICHD project officer. The Steering Committee Chairman is appointed by NICHD and is not a Principal Investigator from any of the Clinical Centers.

SUPPORT Trial Follow-up Subcommittee

The SUPPORT Protocol Subcommittee is responsible for the preparation and maintenance of the protocol, data forms, and manual of operations. This subcommittee will monitor the overall study performance (including protocol compliance) and will report the progress of the trial to the Steering Committee. SUPPORT Subcommittee members are:

Neil Finer, MD

Waldemar A. Carlo, MD,

Edward F. Donovan MD

Michele Walsh, MD

Shahnaz Duara, MD

Rosemary D. Higgins, MD

Abhik Das, PhD

Ruth Everett, RN

Wade Rich, RRT

In addition, Dr. Vohr, as director of the Follow Up Program, will coordinate input from the Follow Up PIs. Timothy P. Stevens, MD, MPH and Peter Szilagyi, MD, MPH from the Department of Pediatrics at the University of Rochester will be instrumental in designing; implementing and executing the clinical studies outlined here and will have significant ongoing involvement with the project.

2.2 Participating NICHD Neonatal Research Network Centers

Centers from the NICHD Neonatal Research Network participating in the trial are listed below. The NICHD center number is indicated in parentheses next to the name of each center. The Neonatal Research Network principal investigators (PIs) are located in the second column, the Follow-up PIs in the third column and the SUPPORT Study PIs in the fourth column.

PARTICIPATING CENTERS	NRN PI	NRN Follow Up PI	SUPPORT STUDY PI
Case Western Reserve Univ. (3) Rainbow Babies and Children's Hospital	Michele Walsh, MD	Dee Wilson, MD	Michele Walsh, MD
University of Texas-Dallas (4)	Charles Rosenfeld, MD	Roy Heyne, MD	Walid Salhab, MD
Wayne State University (5) Children's Hospital of Michigan	Seetha Shankaran, MD	Yvette Johnson, MD	Seetha Shankaran, MD
University of Miami (8) Jackson Memorial Hospital	Shahnaz Duara, MD	Charles Bauer, MD	Shahnaz Duara, MD
Emory University (9) Grady Memorial Hospital	Barbara J. Stoll, MD	Ira Adams-Chapman, MD	Susie Buchter, MD
University of Cincinnati (11) University of Cincinnati Hospital	Edward F. Donovan, MD	Jean Steichen, MD	Vivek Narendran, MD Kurt Schibler, MD
Indiana University (12)	James A. Lemons, MD	Anna M. Dusick, MD	Brenda Poindexter, MD
Yale University (13) The Children's Hospital at Yale – New Haven	Richard A. Ehrenkranz, MD	~~Linda Mayes~~Richard A. Ehrenkranz, MD	Vineet Bhandari, MD
Brown University (14) Women and Infant's Hospital	William Oh, MD	Betty R. Vohr, MD	Abbot Laptook, MD
Stanford University (15) Stanford University Med Center	David K. Stevenson, MD	Susan R. Hintz, MD	Krisa Van Meurs, MD
University of Alabama (16) University of Alabama at Birmingham	Waldemar A. Carlo, MD	Myriam Peralta, MD	Waldemar A. Carlo, MD
University of Texas- Houston (18)	Jon E. Tyson, MD	Jon Tyson, MD	Brenda Morris, MD
Duke University (19)	Ronald Goldberg, MD	Ricki Goldstein, MD	C. Michael Cotten, MD
Wake Forest University (20)	Michael O'Shea, MD	Robert Dillard, MD	Michael O'Shea, MD
Golisano Children's Hospital at Strong (21) University of Rochester	Dale L. Phelps, MD	Gary Myers, MD	Nirupama Laroia, MD
University of California-San Diego (22)	Neil Finer, MD	Yvonne Vaucher, MD	Neil Finer, MD

2.3 Responsibilities of Clinical Centers

The minimum staff required for network participation at each clinical center is the physician Principal Investigator (PI), the Research Coordinator, and telephone interviewers, if interviews are not conducted by the Research Coordinator.

The research coordinator may identify another individual to conduct the telephone interviews. In this situation, it will be the coordinator's responsibility to assure that the interviewer is certified in standardized administration of the questionnaire (see below). The responsibilities of these individuals are described briefly in this chapter and in more detail in subsequent chapters.

The PI or designee is responsible for ensuring the proper conduct of the trial at his or her clinical center (including recruitment and treatment of patients as specified in the protocol), accurate collection of data and transmission of information to the Data Coordinating Center (DCC). Other specific duties include the following:

- Presenting an in-service to the other physicians
- Applying for IRB approval
- Introducing the study to the parents of prospective patients, and obtaining signed informed consent from the parents of eligible infants (in some centers this responsibility may be delegated)
- Reviewing all infants for whom informed consent has been obtained to confirm their eligibility
- Informing the IRB of the study progress.

The Research Coordinator will be responsible for the day-to-day operations of the study at the clinical center, including data collection and management. This responsibility includes the following:

- Collecting information necessary to complete the data collection forms, and coordinating data entry
- Training and certifying the staff in the use of the network computer
- Controlling access to the network computer and ensuring that required back-up, security and confidentiality are maintained
- Responding to edit messages and other communications from the data center
- Distributing updates of the protocol and of the manual of operations to clinical center staff
- Further responsibilities are based on the study administration option chosen by the center.

2.3.1 Delineation of Responsibilities by Study Administration Option

Clinical Centers have the option of administering the follow-up questionnaires to their own patients (Option 1) or having telephone interviewers of the University of Rochester Health Services Research Group administer the follow-up questionnaires to their patients (Option 2). Table 2 indicates which option the centers have chosen.

Table 2. **SUPPORT Trial - Breathing~~Pulmonary~~ Outcomes Study**

NICHD Site	*6, 12 and 18-22 Month Pulmonary Questionnaires Administered By*	Option Number
Alabama	Alabama	1
Brown	Brown	1
Cincinnati	Cincinnati	1
CWRU	CWRU	1
Dallas	Dallas	1
Duke	Duke	1
Emory	Rochester	2
Houston	Rochester	2
Indiana	Rochester	2
Miami	Miami	1
Rochester	Rochester	2
Stanford	Rochester	2
UCSD	UCSD	1
Wake Forest	Wake Forest	1
Wayne State	Wayne State	1
Yale	Yale	1

Regardless of the option chosen, each local center is responsible for obtaining informed consent, administering the NICU Discharge-Baseline Interview (SUPF01) and distributing the respiratory ~~diary~~brochure to parents, as well as tracking patients following discharge. Table 3 further describes the responsibilities of the local center and Rochester in Option 1 and Option 2.

Table 3.	Option 1	Option 2	
	Local Center	Local Center	Rochester
Consent / IRB	✓	✓	
Questionnaire at Discharge	✓	✓	
Patient Tracking	✓	✓	
Questionnaire at 6 & 12 mo.	✓		✓
Questionnaire at 18-22 mo.	✓		✓
Data Entry (questionnaires)	✓		✓

Each of the responsibilities discussed in table 3 above will be discussed separately below.

2.3.2 Consent

For both options, every effort will be taken to enroll ALL SUPPORT patients into the Breathing~~Pulmonary~~ Outcomes Study, including both currently enrolled SUPPORT patients (both patients still in NICU and those discharged from the NICU) and all future enrollees. By obtaining pulmonary outcome data for both current and future SUPPORT patients, death or adverse pulmonary outcome can be analyzed as competing outcomes. Sample consent forms for currently enrolled and future SUPPORT patients are attached.

2.3.3 Discharge Questionnaire

The purpose of the discharge questionnaire is to assure adequate randomization of important covariates affecting outpatient respiratory health and to obtain baseline data on home environment and family history of respiratory diseases. There are a total of 16 questions on the questionnaire; 9 questions on home environment and exposures, 1 question on alternate contact information, 6 questions on family history of allergy and respiratory problems.

Each center, regardless of study option chosen, will administer the discharge questionnaire. This will allow ascertainment of baseline data as well as confirming contact information for the family. For patients enrolled into the ~~Pulmonary~~ Breathing Outcomes ~~Follow up~~ Study after NICU discharge, this questionnaire can be administered prior to the 6 month questionnaire.

After completing the discharge – baseline questionnaire, parents ~~should~~ will be given the respiratory ~~diary~~ brochure ("My Baby's Breathing Book") ~~and instructed to record~~which will ask them to note how often their baby has wheezing or coughing, whether the baby visited a doctor's office, emergency room or was hospitalized for breathing problems. ~~Parents should be asked to gather the diary and any medications or other information about their baby's breathing when the interviewer calls in six months.~~ By presenting the brochure to the family and discussing it with them as they leave the NICU, each family will have opportunity to review the study with study personnel. This is especially important because many families will have committed to the follow up study several months before discharge. When the interviewer calls in six months, parents should be asked to gather any notes, medications or other information about their baby's breathing.

Formatted: Font: Not Italic

2.3.4 Tracking

All centers (Option 1 and 2 centers) will track their own patient's telephone and contact information for the purpose of administering telephone questionnaires at 6, 12 and 18-22 months. This will also help assure attendance at the routine NICHD neurodevelopmental follow up clinic visit 18-22 months.

The following core set of contact information is recommended for all enrolled patients.

- Network number
- Patient Name
- DOB
- Gender
- Name of Prior Interview Respondent (if different than primary care taker)
    - Primary Caretaker Contact Information
        - Name
        - Relationship to patient
        - Mailing address
        - Telephone number #1
        - Telephone number #2
    - Secondary (Backup) Caretaker Information
        - Name
        - Relationship to patient
        - Mailing address
        - Telephone number #1
        - Telephone number #2

2.3.5 Responsibility of Option 1 Centers In Administering Questionnaires at 6, 12 And 18 Months' Corrected Age

Clinical Centers will have the option of administering the follow-up questionnaires to their own patients (Option 1) or having telephone interviewers from the University of Rochester Health Services Research Group administer the follow-up questionnaires to their patients (Option 2).

- Standardization of Interview Technique
  - In order to assure that interviews are administered in a standard and consistent manner, the University of Rochester Health Services Research Group will conduct an Interviewer Certification Program to train interviewers at Option 1 centers and Rochester based interviewers. All interviews must be performed by certified interviewers (see 2.4.7 below).

- Conducting the Interviews
  - Prior to each interview, a postcard will be mailed to the family reminding them to expect a telephone call.
  - For centers that see patients in an office setting, the questionnaire may be administered face to face.

2.3.6 Responsibility of Option 2 Centers In Administering Questionnaires at 6, 12 And 18 Months' Corrected Age

- Upon receipt of RTI reminder, Option 2 Centers will send a postcard to the family reminding them to expect a telephone call.
- Review and update contact information as necessary and fax contact information to the Rochester Health Services Research Group (RHSRG).
- The RHSRG will conduct the telephone interview.
- At the conclusion of each interview, contact information will be confirmed and updated contact information faxed back to the Option 2 Center.

2.3.7 Responsibilities of the University of Rochester Health Services Research Group

- The certification program will consist of two parts.
  - Part 1 - a teleconference training session during which each question on the questionnaires is reviewed and discussed with the interviewers. The goal is to assure that interviewers understand the purpose of each question and, in a standard way, how to deliver the question, elicit an answer and record the interviewee's response.

  - Part 2 will consist of a practice interview in which interviewers from each center interview the Rochester trainer, who simulates a standardized patient. Following the practice interview, the Rochester trainer and practice interviewer will discuss the interview and give feedback.

- Other responsibilities include:
  - Development and distribution of an audio clip of wheezing to be presented along with a verbal definition to the interview respondent to standardize interpretation of wheezing and to minimize ascertainment biases due to language, culture, literacy or interviewing techniques.
  - Maintaining trained Spanish-speaking individuals to conduct the telephone interviews with Spanish-speaking participants from centers choosing Rochester to administer the questionnaire to their patients (Option 2).
  - Spanish language versions of the questionnaires will be created and made available to all centers. The Cornell Translation Service, a University based professional translation service, will be contracted by the University of Rochester to perform the translation.

2.4 Responsibilities of the Data Coordinating Center

The DCC at RTI International is responsible for all aspects of statistical design and analysis as well as data management of the study. In particular, this includes:

- Processing, updating and distributing the protocol and manual of operations
- Developing and distributing the data forms, including periodic updates as necessary
- Developing, testing and implementing the database and other software. Ensuring that data are correct and complete by implementing editing and auditing procedures
- Monitoring the progress and quality of the study
- Preparing interim and final analyses and reports
- Participating in the preparation of presentations and publications relating to the study

The DCC is also responsible for sending monthly reminder reports to Network Centers. For patients enrolled in the Pulmonary Outcomes Study, the DCC will send a monthly reminder to each center with a list of IDs that are due to have questionnaires conducted. The report will include the following:

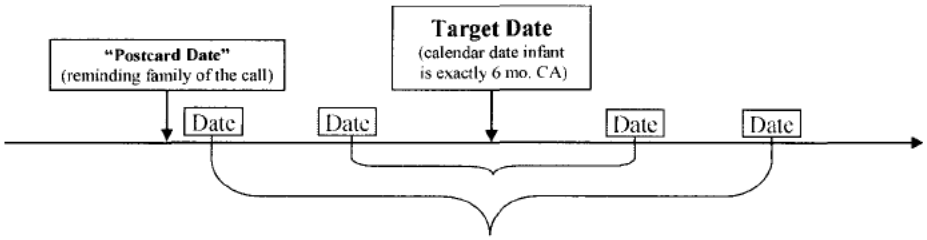
- Network number
- Gestational age
- Gender
- Date of last interview
- Care taker (relationship code) providing the previous interview
- Whether the previous interviews were conducted face to face or by telephone
- List of the 4 interviews that have been completed (CA = corrected age)
- Completed interview dates, dates of previous interviews and interviewee information may be presented as outlined in the table below.

Example table

Example table

Required Interviews	Date	Caretaker Interviewed	Face to Face?
▪ Discharge	__/__/__	_____	Y or N
▪ 6 month CA	__/__/__	_____	Y or N
▪ 12 month CA	__/__/__	_____	Y or N
▪ 18-22 month CA	__/__/__	_____	Y or N

- Target date for the current interview with windows within which interview should be accomplished, goal window (target date ± 2 weeks) and acceptable window (target date ± 4 weeks)
- A "postcard date", 5 weeks prior to the contact, when a postcard might be sent to the family reminding them of the upcoming call or visit



2.5 Responsibilities of NICHD

In addition to its role as a funding agency, the NICHD participates in the activities of the cooperative agreement by being represented on the Steering Committee. The Program Official also participates in the development of protocol and in assisting the Steering Committee in the coordination of the studies conducted by the Network. The NICHD Program Official, in conjunction with the RTI Principal Investigator is responsible for monitoring site performance of all participating centers. The Program Official has the following responsibilities:

- Assistance in the development of the study protocol.
- Assistance in the development of capitation-based budgets, including the identification of study costs and special institutional needs.
- Allocation of network resources to meet study needs.
- Facilitation of training meetings, site visits, and subcommittee meetings.
- Participating in preparation of publications.

Chapter 3
Screening, Eligibility, Consent

3.1 Study Population

This follow-up study will include all surviving infants enrolled, randomized and treated as part of the multi-center NICHD Neonatal Research Network SUPPORT Trial, which were inborn infants of 24 0/7ths to 27 6/7th weeks at birth for which a decision was made to provide full resuscitation as required. Infants 27 weeks or less gestation (completed weeks by best obstetric estimate) were enrolled.

Inclusion Criteria

- Enrollment in the SUPPORT Trial
- Survival to hospital discharge
- Consent for enrollment into the Breathing~~Pulmonary~~ Outcomes ~~Follow-up~~ Study, obtained either at the time of enrollment into the SUPPORT Trial or separately.

3.2 Exclusion Criteria

- Refusal of informed consent

3.3 Informed Consent

Every effort will be taken to enroll ALL SUPPORT Trial patients into this follow-up study, including currently enrolled SUPPORT patients (both patients still in NICU and those discharged) and future enrollees. By obtaining pulmonary outcome data for both current and future SUPPORT patients, death or adverse pulmonary outcome can be analyzed as competing outcomes. Each local center will be responsible for obtaining informed consent for the Breathing Outcomes~~Follow-up~~ Study regardless of whether they are administering the follow-up questionnaires to their patients or Rochester is conducting the telephone interviews.

For future enrollees in the SUPPORT Trial, consent for the Breathing Outcomes~~Follow-up~~ Sstudy will be obtained at the time of enrollment in the main trial. As described in the SUPPORT Trial Manual of Operations, these infants will be recruited for the study by approaching one or both parents at the time of admission to the hospital at risk for premature delivery at 27 weeks or less. It is anticipated that, whenever possible, the parents will be approached by study personnel to discuss the trial and obtain an informed consent for the participation of the infant at delivery. Randomization will be by family, thus all offspring will be randomized to the same trial arms, provided adequate equipment and personnel are available at the time of delivery. Sample consent forms for currently enrolled and future SUPPORT patients are attached (Appendix C).

A Study Brochure will be given to each family at the time of the discharge interview. The brochure reviews the study and its commitments and also asks families to make observations about the baby's breathing symptoms and treatments. Reviewing the brochure is especially

Formatted: Indent: Left: 0"

important because many families will have committed to the follow up study several months before discharge.

3.4 Screening Procedures

This follow-up study will include all surviving infants enrolled, randomized and treated as part of the NICHD Neonatal Research Network SUPPORT Trial.

For future enrollees in the SUPPORT Trial, all admissions for threatened premature delivery will be screened on a daily basis to ensure that eligible patients can be enrolled. Obstetrical colleagues at each participating institution will be informed of the nature of this study and encouraged to discuss this study with their patients at risk of premature delivery. The study coordinator at each site will maintain a screening log of potentially eligible patients. In addition, the usual practice of neonatal consultation for all such at risk deliveries will provide a second opportunity to approach mothers with fetuses at risk of preterm delivery.

Chapter 4
Randomization

4.1 Randomization Procedures

Randomization for the NICHD Neonatal Research Network SUPPORT Trial was stratified by gestational age group (24 - 25 6/7 and 26 - 27 6/7) and occurred prior to delivery for consented deliveries. The randomizations were performed by utilizing specially prepared envelopes. The Data Center prepared brown sealed envelopes which contained the identity of the treatment combination that were assigned to the infants enrolled into the study. Deliveries were randomized as a unit, thus multiples, twins, triplets etc were randomized to the same arm of the trial. One envelope corresponded to the delivery of a consenting mother regardless of the number of babies delivered so that all babies from a given delivery received the same treatment combination.

Refer to Section 4.1.1 of the NICHD Neonatal Research Network SUPPORT Trial Manual of Operations (MOO) for more information on randomization and masking as well as storing and assigning oximeters that occurred during the main study.

During the Breathing Outcomes~~Follow-up~~ Study activities, research coordinators and telephone interviewers, if different from the research coordinators, will remain blinded as to whether infants were randomized to the control or treatment group.

Formatted: Font: Arial

Chapter 5
~~Follow-up~~Breathing Outcomes Study Procedures

Formatted: Font: Arial

Formatted: Font: Arial

5.1 SUPPORT Trial Study Interventions

Refer to Chapter 5 of SUPPORT Trial Manual of Operations (MOO) for more information on the study interventions and the procedures for the treatment groups. The same questionnaires will be administered to both treatment groups in the ~~Follow-up~~ Breathing Outcomes Study.

5.2 ~~Pulmonary Follow Up~~Breathing Outcomes Study Interventions

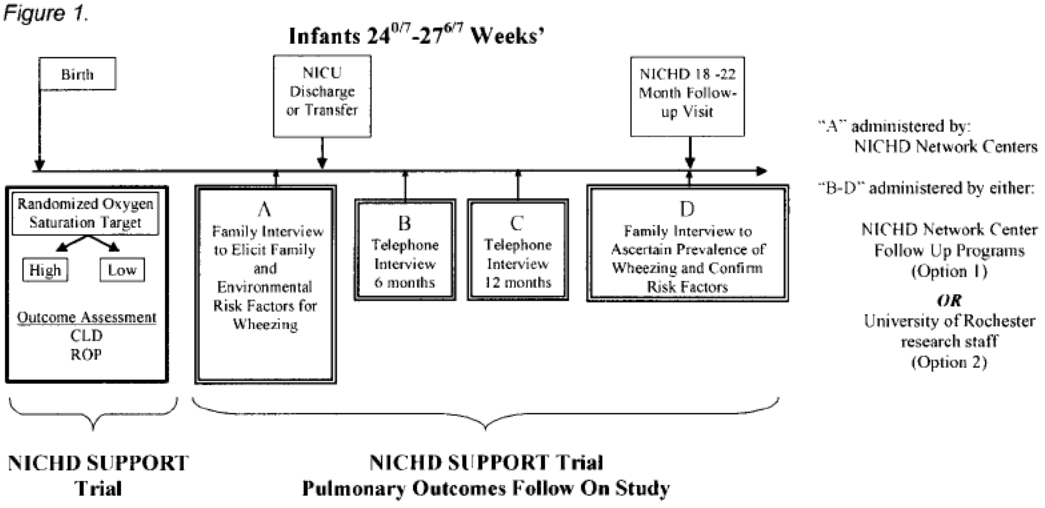
Before delivery, infants will be randomized according to the 2x2 factorial design of the SUPPORT Protocol.

The SUPPORT ~~Follow-up Study of Pulmonary~~Breathing Outcomes Study begins just prior to NICU discharge. See Figure 1 for a diagram of the SUPPORT Trial ~~Follow-up~~Breathing Outcomes Study procedures.

Four questionnaires will be administered at approximately 6 month intervals until the baby is 18-22 months' corrected age according the schedule outlined in Figure 1. Each interview will collect a 6 month interval history, which, when taken together, will provide a complete respiratory history over the first 18-22 months' corrected age. If a questionnaire is not completed, the subsequent questionnaire will include the full interval history since the last completed questionnaire.

SUPPORT Trial Follow-up Study

Figure 1.



DESCRITION OF QUESTIONNAIRES

A) Discharge Questionnaire Administered by Network Centers

The discharge interview consists of a primary caretaker (parent or guardian) interview to elicit family and environmental risk factors for wheezing and cough. The family interview will be administered at each participating Network Center by site study nurses prior to NICU discharge or transfer. The questions are based on intake questions used by the Tucson Respiratory Study and are designed to elicit family history of asthma, atopy, and home environmental exposures and to identify likely care givers. This interview will be administered to the parent or guardian by trained study staff prior to NICU discharge or within 30 days after NICU discharge. For patients enrolled into the Breathing Outcomes Study after NICU discharge, this questionnaire can be administered prior to the 6 month questionnaire.

The purpose of the discharge questionnaire is to assure adequate randomization of important covariates affecting outpatient respiratory health and to obtain baseline data on home environment and family history of respiratory diseases. There are a total of ~~16~~ 25 questions on the questionnaire; the first 6 are demographic, ~~9~~ 11 questions are on home environment and exposures, 2 questions are on diet, 1 question is on alternate contact ~~information,~~information, and a separate 5 ~~6~~ questions are on family history of allergy and respiratory problems.

Each center, regardless of study option chosen, will administer the discharge questionnaire and perform data entry. This will allow ascertainment of baseline data as well as confirming contact information for the family.

B) Respiratory History Questionnaires Administered at 6 and 12 Months' Corrected Age

The purpose of this questionnaire is to obtain an **interval** respiratory history. Questions are designed to collect respiratory history in areas outlined in the table at right. For centers choosing Option 1, interviews may be conducted either by telephone or face to face. For centers choosing Option 2, interviews will be conducted long distance by telephone from The Rochester Health Services Research Group to the family.

Outcome	Question No.
Respiratory Symptoms	9, 10, 13-15
Quality of Life	11, 12
Health Services Utilization	
Office	6
Emergency Department	7
Hospitalization	8
Medication Use	27
Oxygen Use	26
Preventive Services	24, 25
Exposures	16-23

C) Respiratory and Environmental Exposure History Questionnaires Administered at 18-22 Months' Corrected Age

Formatted: Font: Bold, Not Italic

Formatted: Indent: Hanging: 0.25", Tab stops: 0.5", Left + Not at 0.75"

The purpose of this questionnaire is to obtain an **interval** respiratory history and to identify environmental exposures that may increase the likelihood of symptomatic airway dysfunction. Questions are designed to ascertain the frequency and severity of wheezing

and cough episodes and to assess the need for outpatient pulmonary care. In addition, a history of atopy is elicited. There are a total of ~~30~~ 34 questions, encompassing the 27 questions from the discharge and 6 and 12 month questionnaires and 7 concerning infection and allergy history.

This parent interview may also be administered either by telephone prior to the regularly scheduled 18-22 month NICHD developmental follow-up clinic visit or face to face at the time of the visit. Contacting parents prior to the office visit will help improve the Developmental Follow Up Clinic attendance rate. Otherwise, the clinic visit will provide a back up means to contact the family. The 18-22 month interview will be conducted either by the local NICHD Follow Up Program (Option 1) or long distance from Rochester (Option 2), based on center preference (see table 2 below).

5.3 Administration of the ~~Follow-up~~Breathing Outcomes Questionnaires

- The questionnaires are for research only. Caretakers, parents or guardians expressing concern regarding the child's breathing should be encouraged to discuss their concern with the family's primary care physician. Diagnostic or treatment advice should NOT be offered as part of the interview.

5.4 Protocol Violations

The occurrence of any one of the following criteria will determine whether an individual infant will be considered a protocol violation:

- Interview occurring outside the acceptable window (target date + 4 weeks)
- Missed interview

In both of these cases the interview should be conducted at the next available opportunity and should encompass respiratory health since the prior interview.

All protocol violations will be reviewed by the center PI who will discuss each protocol violation with the involved clinicians, identifying steps to avoid future violations.

5.5 Adverse Events

We anticipate no risk to the patient from this observational follow-up study.

Serious adverse events were anticipated in the main SUPPORT Trial for this vulnerable population. Refer to Section 5.5 of the NICHD Neonatal Research Network SUPPORT Trial MOO for more information on adverse event reporting and monitoring.

Chapter 6
NICU Discharge-Baseline Interview

Introduction

The purpose of the discharge questionnaire is to assure adequate randomization of important covariates affecting outpatient respiratory health and to obtain baseline data on home environment and family history of respiratory diseases. There are a total of ~~16~~ 25 questions on the questionnaire; 6 questions on demographics, ~~9~~ 11 questions on home environment and exposures, 2 questions on diet, 1 question on alternate contact information, and a separate ~~5~~6 questions on family history of allergy and respiratory problems.

Each center, regardless of study option chosen, will administer the discharge questionnaire and perform data entry. This will allow ascertainment of baseline data as well as confirming contact information for the family.

Instructions for Completing the NICU Discharge-Baseline Interview (SUPF01)

Timing of the Interview:

This interview should be administered to the parent/guardian by a trained study nurse prior to or within the first 30 days following NICU discharge. If for any reason the infant is enrolled into the Pulmonary Outcome Study later than 30 days following NICU discharge, the questionnaire should be administered prior to interval questionnaires (SUPF02 or SUPF03)

Heading- Infant's Identification
The following information is included in the heading section of all patient specific data forms: Center, Site, Network Number, SUPPORT Follow-up Number, Birth Number and Mother's Initials **(optional).** This information should be completed on the first page of the interview and the SUPPORT Follow-up Number written on subsequent pages in case the completed form pages are separated.

6.1 Conducting the Interview

6.1.1 Initiating the interview:

Script Introducing the Study:
N.B. The interviewer's script is in italics and enclosed in quotations.

"Premature babies are more likely than full term babies to have breathing problems after discharge from the NICU. The purpose of this study is to see whether or not the treatments your baby received as part of the SUPPORT Study improves your baby's breathing in the 18-22 months following the baby's due date.

As part of this study, we will contact you every 6 months or so to ask you questions about your baby's breathing. The questions will be about your baby's breathing symptoms, especially wheezing and coughing, and about your baby's need for medical visits and treatments for breathing problems.

By wheezing we mean an expiratory sound (a sound that is made when breathing out, not in) that comes from the chest, sometimes described as whistling or musical.

We have prepared a ~~diary~~ brochure for you that describes the study and outlines important characteristics of your baby's breathing. ~~to help you keep track of your baby's breathing,~~ especially breathing problems and treatments.

Give ~~diary~~brochure

~~To complete the diary, please record how often your baby has wheezing or coughing, whether your baby visited a doctor's office, emergency room or was hospitalized for breathing problems.~~

When we call, we'd like you to gather ~~the diary and~~ any notes, medications or other information about your baby's breathing. We will ask questions about how often your baby has wheezing or coughing, whether your baby visited a doctor's office, emergency room or was hospitalized for breathing problems, and whether your baby has needed breathing medicines or treatments. If you wish, you may use the brochure to make notes about your baby's breathing.

In order to help us understand your baby's breathing and risk for breathing problems at home, we'd like to ask you a few questions about your home and about whether breathing problems run in the family. As with all information we collect, the answers to these questions will be kept confidential."

Please confirm the study baby's identity.

"We will be discussing, patient name. He/she is a boy/girl born on birth date"
Question 1.
Child's Name:
Please enter the child's name including, nickname that he/she will be called.

Question 2.
Enter the date of the interview in "mm/dd/yyyy" format.

Question 3.
Child's Sex:
Please enter the child's sex.

Question 4.
Child's Birthdate:
Please enter to the child's birth date in "mm/dd/yyyy" format.

Please confirm the identity of the caretaker being interviewed.
Question 5.
"With whom am I speaking?
Question 5a.
What is your relationship to the baby?"

Please specify the primary caretaker's name and relationship to the infant using the relationship codes used in the Network Follow up Program, Appendix B.

Every effort should be made to interview the primary caretaker during this interview and all subsequent interviews (6, 12 and 18 months). If the mother resides in the same household as the child, the mother is the primary caretaker. If each caretaker has exactly 50% custody, record as the primary caretaker, the person who comes in for the discharge. This person should answer all subsequent interviews, if possible.

APPENDIX B OF THE ~~FOLLOW-UP~~BREATHING OUTCOMES MANUAL OF PROCEDURES

RELATIONSHIP CODES

The following codes are used to identify the primary caretaker.
001 - Mother of Child
002 - Father of Child
011 - Husband, Significant Other (SO)(if different from 002)
012 - Wife, Girlfriend (if different from 001)
021 - Maternal grandmother
022 - Paternal (SO) grandmother
031 - Maternal grandfather
032 - Paternal (SO) grandfather
041 - Maternal aunt
042 - Paternal (SO) aunt
051 - Maternal uncle
052 - Paternal (SO) uncle
061 - Brother
062 - Step Brother
071 - Sister
072 - Step Sister
081 - Maternal female cousin
082 - Paternal (SO) female cousin
091 - Maternal male cousin
092 - Paternal (SO) male cousin
101 - Other maternal relative
102 - Other paternal (SO) relative
201 - Foster mother
202 - Foster father
301 - Adoptive mother
302 - Adoptive father
401 - Other non-relative
402 - Social worker/case worker
501 - Staff in congregate care
502 - Still hospitalized
504 - Unknown

Question 6.
Type of Interview:
Record whether the interview conducted face to face or by telephone.

Interview Begins
(N.B. The interviewer's script is in italics and enclosed in quotations)

Script: ***"At this time, we would like a little information about the environment in which your new child will grow up."***

Question 7.
"First, how many people normally live with you in your home for at least 6 months of the year?"
Enter the total number of household members. A household member is a person who spends more than 7 nights in the home over a two week period for at least 6 months of the year.

Question 8.
"After the first few months, will your child be sharing a room with other family members on a regular basis?"
Enter YES if child shares a room with another household member more than 7 nights in a 2 week period.

Question 8a.
If answer to 8 is YES: *"How many people will sleep in the same room with him/her?"*
Please record how many people will sleep in the same room with the child.

Question 9.
"How many rooms are there in your house, excluding closets and bathrooms?" Record how many rooms in the space provided.
A room is a space within the house in which residents play, sleep, work or eat.

Question 10.
"Do you have any pets inside the home?"
If yes record, *"How many dogs in the home? Cats in the home? Do you have other pets in the home? What kinds? How many?"*
If interviewee reports pets, please record the number of dogs and cats separately. Group all other pets together and record total number of pets that are neither a dog nor a cat.

Question 11.
"Does your home or apartment have air conditioning or some kind of cooling?"
Please enter "Yes" or "No"
Question 11.a-11.c_-Please record whether family has air conditioning or evaporative cooling. If family uses another type of home cooling system, please answer YES and record type.

Question 12.
"How is your home heated?, With steam or hot water, with a gas furnace, with electricity, with a wood stove, or something else? "
Please prompt by reading each of the listed heating options. Record all heating methods used in the home or apartment. If more than one heating type is used, please record all heating types used. Steam or hot water heat uses upright radiators or baseboard units. A central gas furnace uses forced air vents that blow air into the room. Included in wood stove heat is use of a fireplace for heat, including fireplaces with energy ~~conserving~~ efficient "inserts".

Question 13.
"What fuel is used most for cooking in your home?"
There is no need to prompt with each alternative cooking fuel. Please record one primary cooking method used in the home or apartment.

Formatted: Indent: Left: 0"

Scripting: "The next questions are about your baby's diet ....."

Question 14.
"Is your child receiving only breast milk, only formula, or both breast milk and formula?"
Record response

Question 14a.
If reply to 14 is only breast milk (choice #1),
"Will the breast milk be supplemented with formula in the next 6 months?"
Please record "Yes", "No" or "Don't Know

Question 14b.
"If so, when do you think the supplement will begin?"
Enter YES, if breast milk will be supplemented with formula. Enter the number of months from date of interview that breast milk will be supplemented with formula.

For interviews conducted after the target period of 30 days following NICU discharge, Question 14 should be stated as, "At the time of NICU discharge was your child receiving" (read all answer choices).

Formatted: Indent: First line: 0.06"

Scripting: "The next question are about your baby's care environment ....."

Question 15.
"Does the mother plan to work outside the home within the next year?"
Select from responses below.
1. Yes
2. No
3. Don't Know

For interviews conducted after the target period of 30 days following NICU discharge, Question 15 should be stated as, "Does the mother plan to work outside of the home within the first year of the child's life?"

Formatted: Indent: Left: 0", First line: 0"

Scripting: "The next questions are about smoke exposure....."

Question 16.
*"Which one of the following 3 statements best describes the situation regarding smoking in your child's **home?**.....Read all options to the interviewee before recording a response: Smoking is allowed in any common room of the home, smoking is limited to part of the house where the child rarely goes, there is no smoking inside at all?*

Question 16a.
If answer to question 16 is "there is no smoking in the house at all", then ask question 13a, *"Are there any exceptions to this situation?"*

If respondent reports any exceptions, record "Yes". If no, skip to question 17.

Question 16b.
If answer to 16a is "Yes", then ask question16b.
"Under what circumstances are the exceptions allowed?"
Record a brief response as free text.

Question 17.
"*Which one of the following 5 statements best describes the situation regarding smoking in your **car?**.... Read all options to the interviewee before recording a response: Smoking is usually or always allowed, smoking is sometimes allowed, smoking occurs in the car only when the child is not inside, there is no smoking inside the car"*
Record the response as it applies to the main automobile in which the baby rides. If family does not ride in a car (public transportation only or baby doesn't leave home), record response #1.

Questions 17a and 17b. Responses questions to17a and 17b are completed similarly to questions 16a and 16b.

Question 18.
"How often have you smoked since this child was born?"
Please record response, never means never, daily means at least once per day, record occasionally for any quantity between never and daily.

Question 19.
"Altogether, how many people in the child's home smoke?" _____people
Record the number of people who reside in the home (spend more than 7 out of 14 nights in the home) who smoke. Any smoker counts, whether they smoke in the home, outside the home or at some distant location.

Family History Form

Scripting: "In the next section, we'd like to know what breathing and allergy problems run in the family."

Administer the attached Family History Questionnaire using the follow script.

Mother:

"We'll start with the baby's mother. How old is the baby's biologic mother? Does she have bronchitis, emphysema, COPD, bronchiectasis, asthma, inhaled allergies, or food allergies?"
Circle Yes, No, or DK (Don't Know).

"Does she (you) have any other chronic respiratory illnesses?"

"How often do you smoke in the baby's home?"

Father:

"For the baby's biologic father, is he living? How old is he? Does he have bronchitis, emphysema, COPD, bronchiectasis, asthma, inhaled allergies, or food allergies?"

"Does he have any other chronic respiratory illnesses?"
Circle Yes, No, or DK (Don't Know).
"How often does he smoke in the baby's home?"
Complete the remainder of the table by collecting the same medical history using the script above.

Please complete a family history for each of the family relationships listed, mother, father, maternal grandmother (Mom's biologic Mother), maternal grandfather (Mom's biologic Father), paternal grandmother (Dad's biologic Mom), and paternal grandfather (Dad's biologic Father). For each relative above, enter whether they have ever had any of the listed respiratory problems. The interviewer need not explain each diagnosis, but may offer an explanation if asked. Record only those responses that pertain to the baby's biologic relatives. If information is not known by the respondent, record as "DK" (Don't Know).

Question 20.
"Finally, which friend or relative is most likely to be able to contact you 6 months from now in case we lose contact with you?"

Record the information for an alternate contact person who is unlikely to move and the most likely to know the baby's family most recent residence / phone number.

Chapter 7
6 and 12 Month Pulmonary Outcome Questionnaires

Introduction

The purpose of this questionnaire is to obtain an **interval** respiratory history, such that when the 6, 12 and 18-22 month questionnaires are taken together, a complete respiratory history over the time period is collected.

The questionnaire will be administered to the parent or guardian by a certified telephone interviewer at 6 months' CA and again at 12 months' CA.

Centers choosing Option 1 will administer the questionnaire using a certified local interviewer and locally maintained contact information. For centers choosing Option 2, a Rochester Health Services Research Group (RHSRG) certified interviewer will conduct the interview via long distance telephone call using contact information maintained by the local center and faxed or emailed to the RHSRG.

Instructions for Completing the 6 and 12 Month Questionnaire (SUPF02)

Instructions for Completing the NICU Discharge-Baseline Interview (SUPF01)

Timing of the Interview:

This interview should be administered by a certified study interviewer. The target window for this interview is at the following corrected ages: 6 months ± 2 weeks and 12 months ± 2 weeks, with an acceptable window of 6 months ± 1 month and 12 months ± 1 month. If for any reason the infant is enrolled into the Pulmonary Outcome Study later than this time window or becomes available for a Pulmonary Outcomes Interview outside this window, the questionnaire should be administered, collecting an interval history from the time of NICU discharge or the most recent interview, whichever is most recent.

Heading- Infant's Identification
The following information is included in the heading section of all patient specific data forms: Center, Site, Network Number, SUPPORT Follow-up Number, Birth Number and Mother's Initials **(optional).** This information should be completed on the first page of the interview and the SUPPORT Follow-up Number written on subsequent pages in case the completed form pages are separated.

7.1 Conducting the Interview

7.1.1 Initiating the interview:

Please request and confirm the identity of the caretaker who completed the initial interview.

Every effort should be made to interview the primary caretaker who completed the initial interview (hereafter referred to as the primary respondent) during this interview and all subsequent interviews (6, 12 and 18 months). If the mother resides in the same household as the child, the mother is the primary caretaker. If each caretaker has exactly 50% custody,

record as the primary caretaker, the person who comes in for the discharge. This person should answer all interviews, if possible.

The interviewer will need to ask for the primary respondent. In the event that the primary respondent is not available, arrangements should be made to call back at a time when the primary respondent will be free to complete the interview. At least 3 call attempts should be made to reach the primary respondent, after that a secondary respondent, who is familiar with the baby and his or her respiratory health, can be identified to complete the interview.

Introduction Script:
When parent or primary care giver is on phone:

"Hello, my name is <your name>. I am calling from the <NICHD Center>. As you probably remember, when you were in the NICU you enrolled in our study about respiratory health of premature infants. I am calling to ask you some questions about your baby's breathing. It will take about 10-20 minutes to complete. Is this a good time for you?"

"Before we begin this interview, it would be helpful if you could gather ~~the breathing diary given to you when you left the NICU as well as~~ any notes you have about your baby's breathing as well as any medications your child has been prescribed or has been taking and have them in front of you. As with all information we collect, the answers to these questions will be kept confidential."

Question 1.
Please enter date of the interview.

Please confirm the identity and contact information for the study baby to be interviewed.

"We will be discussing, patient name. He/she is a boy/girl born on birth date"
Child's Name:
Please enter the child's name.

Child's Birthdate:
Enter to the child's birth date in "mm/dd/yyyy" format.

Child's Telephone Number:
Enter the telephone number to the child's home.

Child's Address:
Enter the address of the child's home.

Alternate Contact Information
Which friend or relative is most likely to be able to contact you 6 months from now in case we lose contact with you?"

Confirm the contact information for an alternate contact person who is unlikely to move and the most likely to know the baby's family most recent residence / phone number.

Question 2a. and 2b.
Enter name and relationship code of the person being interviewed.
Please specify the primary caretaker's name and relationship to the infant using the relationship codes used in the Network Follow up Program.

Question 3.
Type of interview.
Please specify and record whether the interview was administered face to face or via telephone.

Question 4.
Location of Interview.
Please specify and record whether the interview was administered at the local center (Option 1) or by the Rochester site (Option 2).

Instructions:
Parents or guardians expressing concerns regarding their child's breathing should be advised to discuss them with the family's primary care physician.

Where the phrase "last contact" is used below, please substitute with the most specific relevant time prompt, e.g. for the 6 month interview, refer to "since NICU discharge"; for the 12 month interview, refer to "over the past 6 months", etc.

Interview begins:
(N.B. The interviewer's script is in italics and enclosed in quotations)

Scripting:
"Some of these questions will be familiar to you. Since we last spoke (__ __) months ago on (__ __/__ __/__ __) we want to learn what changes, if any, there have been to your child's health. We are especially interested in any breathing problems your child may have....."

Question 5.
"Has the child been with you during the past 6 months?"
Please enter "Yes" or "No". If child has been with the interviewee less than 6 months, please enter "No".

Scripting: "Since <our last contact> with you about your child....."
Please replace the phrase "our last contact", with an interview specific prompt, e.g. "since discharge from the NICU" at the 6 month interview or "since our telephone conversation 6 months ago", for the 12 and 18 month interviews. Equivalent phrases may be used.

Question 6.
"How many times has your child visited a doctor's office?" |___|___| times
Record the number of times that the baby visited the doctor's office for any reason.

Question 6a.

"How many of these times were because of wheezing or breathing problems?"
Record the number of times that the baby visited the doctor's office with breathing problems as one of the 2 major concerns for the visit.

Scripting: "Since <our last contact> with you about your child....."
Please replace the phrase "our last contact", with an interview specific prompt, e.g. "since discharge from the NICU" at the 6 month interview or "since our telephone conversation 6 months ago", for the 12 and 18 month interviews. Equivalent phrases may be used.

Question 7.
"How many times has your child visited an Emergency Department (Emergency room)?"
|___|___| times
Record the number of times that the baby visited the emergency department or emergency room for any reason.

Question 7a.
"*How many of these times were because of wheezing or breathing problems?*"
Record the number of times that the baby visited emergency services with breathing problems as one of the 2 major concerns for the visit.

Question 8.
"How many times has your child stayed in the hospital for 1 or more nights in a row?"
|___|___| times
Record the number of times the baby was hospitalized for any reason, i.e the number of hospitalizations, not the number of hospitalized days.

Question 8a.
"How many of these times were because of wheezing or breathing problems?" |___|___| times
Record the number of times that the baby was hospitalized with breathing problems as one of the 2 major concerns for the visit.

Script:

"The next questions are about your baby's breathing. .....

The first question is about wheezing. By wheezing we mean an expiratory sound (a sound that is made when breathing out, not in) that comes from the chest, sometimes described as whistling or musical."

Question 9.
"Since <our last contact> with you, has your baby's chest sounded wheezy or whistling?"
Enter yes if the respondent reports that the baby's chest has sounded wheezy or whistling. The interviewer may repeat the verbal and audio descriptions of wheezing may be repeated to the respondent. If respondent answers "I don't know", interviewer should ask respondent to think

back over the time period, repeating the description. If parent is still not sure, record "don't know".

Question 9a.

"Has your baby's breathing sounded like this?" ***(play audio clip of wheezing).***

This question is intended for all respondents, regardless of whether they reported wheezing in question 9. The audio clip is from a patient with severe, audible wheezing and represents only one of many manifestation of wheezing breathing sounds. If asked, the interviewer may say that this represents just one type of wheezing. We wish to know about all wheezing and therefore we asked two questions.

Record response, "Yes" or "No". If respondent replies "no" or "don't know", interview skips to question 10. If yes, proceed to questions 9b-g.

Question 9b.

"Has this occurred with colds?"

A "cold" is an upper respiratory infection; other phrases for a "cold" include, "head cold", "rhinitis, "runny or water nose" or "sniffles". A cold may be complicated by an otitis media (ear infection).

A "cold" does not include "chest cold", "bronchitis", "pneumonia", or "bronchiolitis".

Question 9c.

"Has your child's chest sounded wheezy or whistling apart from colds?"

Enter "yes" if the baby had wheezy or whistling in the chest at a time when he / she did not have a cold.

Question 9d.

"During what month did your child's chest first sound wheezy or whistling?"

_____ month ____ year

Please record the month and year during which the child's chest first sounded wheezy or whistling. The respondent may indicate the child's age at which the child's chest first sounded wheezy or whistling. The interviewer should record the month and year of the event.

Here the month and year, rather than the age, that the symptoms began is recorded in an effort to avoid confusion regarding chronologic and corrected ages.

The next 4 questions use similar phrases and the same response options. Please emphasize the phrases which are unique in each question ("on average" or "worst two week period", "daytime" or "nighttime"). If the respondent gives the same response to 5e as 5f, please confirm with the respondent that 5e refers to "on average" and that 5f refers to the "worst two week period".

Question 9e1.

*"~~Over the past 6 months~~Since our last contact with you, **on average**, how often has your child's chest sounded wheezy or whistling during the daytime? Would you say never, twice a week, more than 2 times a week, but not every day, every day, but not all the time, everyday, all the time."*

Record response. Interviewer may repeat the choices or help respondent settle upon the choice.

Question 9e2.

*"~~Over the past 6 months~~Since our last contact with you, **on average**, how often has your child's chest sounded wheezy or whistling during the nighttime? Would you say never, twice a week, more than 2 times a week, but not every day, every day, but not all the time, everyday, all the time."*

Record response. Interviewer may repeat the choices or help respondent settle upon the choice.

Question 9f1.

*"Since our last contact with you~~Over the past 6 months~~, **during the worst 2 week period,** how often has your child's chest sounded wheezy or whistling during the daytime? Would you say never, twice a week, more than 2 times a week, but not every day, every day, but not all the time, everyday, all the time."*

Record response. Interviewer may repeat the choices or help respondent settle upon the choice.

Question 9f2.

*"Since our last contact with you~~Over the past 6 months~~, **during the worst 2 week period,** how often has your child's chest sounded wheezy or whistling during the nighttime? Would you say never, twice a week, more than 2 times a week, but not every day, every day, but not all the time, everyday, all the time."*

Record response. Interviewer may repeat the choices or help respondent settle upon the choice.

Question 9g.

"Since our last contact with you, has your child ~~taken any medicine prescribed~~been diagnosed with wheezing ~~for wheezing~~?"

Record "Yes" or "No". Physician diagnosed wheezing, wheezy or whistling breath sounds should be recorded as a "Yes" response.

Formatted: Indent: Left: 1", First line: 0"

Question 10.

"Since our last contact with you, has your child had a cough for 3 or more days when he/she did not have a cold?"

Record whether the baby coughs for more than 3 days when otherwise well. Do not include coughing associated with eating, drinking or choking. See question 9 for clarification of phrase "cold".

Question 10a.

"At what time of the day has this cough usually occurred? In the morning; shortly after rising; later in the day; during the night; no relation to time of day?"

Interviewer should read all responses to the respondent and circle all that apply.

Question 10b.

"Has he/she coughed on most days for as much as 2 to 3 months?"

Please record "Yes" or "No"

Question 10c.

"During what month did your child first develop the cough?"

Record month and year that the cough first developed, when the respondent recognized the cough whether or not they view it as a problem.

Question 10d.

"Has your child's chest ever sounded wheezy or whistling with episodes of coughing?"

Record yes if the respondent associates wheezing or whistling breath sounds with the presence of the cough.

Questions 10e1-10f2. Questions 10e1-10f2 are completed similarly to questions 9e1-9f2.

Question 11.

*"~~Over the past 6 months,~~ Since our last contact with you, **on average**, how many **days per month** did you have to change your daytime or evening plans because of your child's breathing problems: Was it…*

None, we never had to change plans

More than none, but less than 3 days,

3 to 6 days or

7 or more days."

Please read the choices to the respondent and record their response. The question is designed to determine the number of days that the respondent reports having to change plans because the baby's breathing is different from baseline. An example of a changed plan includes withholding the baby from a planned daycare or babysitting situation because he / she is wheezing.

This does not include preventive avoidance, such as avoiding social situations or trips because the baby might get sick or may be exposed to another child. The interviewer may assist the respondent in selecting ~~a number by establishing a~~ a response by repeating the choices ~~range~~, then having the respondent select a specific answer.

Question 12.

Formatted: Font: Italic
Formatted: Indent: First line: 0.5"
Formatted: Font: Italic
Formatted: Indent: Left: 1", First line: 0.5"
Formatted: Indent: Left: 0"
Formatted: Font: Italic
Formatted: Font: Italic
Formatted: Indent: First line: 0.5"

"Since our last contact with you, ~~Over the past 6 months,~~ ***during the worst 2 week period****, how many* ***days*** *did you have to change ~~for~~ your daytime or evening plans because of your child's breathing problems: Was it…*

None, we never had to change plans
More than none but less than 3 days,
3 to 6 days or
7 or more days."

~~"|__|__|__| # of days~~

———Interviewer should emphasize the "worst 2 week period". Record response using criteria similar to those in Question 11.

Formatted: Indent: Left: 0.5"

The next 4 questions relate to respiratory diagnoses that may be associated with wheezing and airway dysfunction, either directly, as secondary symptom or as a condition that may be confused with airway dysfunction.

Question 13.
"Since our last contact with you, has your child had asthma, ~~or~~ reactive airways disease or a BPD flare-up diagnosed by a doctor?"
Record response, either "Yes" or "No". If respondent does not recognize the condition, record "No".

Question 14.
"Since our last contact with you, has your child had bronchiolitis, bronchitis, or pneumonia diagnosed by a doctor?"
Record response, either "Yes" or "No". If respondent does not recognize the condition, record "No".

Question 15.
"Since our last contact with you, has your child had croup diagnosed by a doctor?"
Record response, either "Yes" or "No". If respondent does not recognize the condition, record "No".

Script: "The next question are about your baby's diet……"

Question 16.
"In the past 6 months, did your baby receive mother's breast milk, either at breast, from a bottle or through a tube?"
If baby received any breast milk, record "Yes".

If yes to Question 16, answer question 16a and 16b, if "No", skip to Question 17:

Question 16a.
"For how many months did your child receive breast milk? Would you say? ….Less than 1 month, 1-3 months, 4-6 months?"
Record duration of time that the baby received any breast milk.

Question 16b.

"For how many months did your child receive breast milk for more than half of his/her feedings? Would you say… Less than 1 month, 1-3 months, 4-6 months?"

Record duration of time that the baby received more than ½ of feedings from breast milk, provided by any route.

A mother who fed her infant breast milk 25% of the time and formula 75% of the time, weaning the baby at 4 months, would answer "yes" to question 16, "4-6 months" to question 16a, and "less than 1 month" to question 16b.

Formatted: Right: 0"
Formatted: Space Before: 0 pt
Formatted: Right: 0", Space Before: 0 pt

Script: "***The next questions are about smoke exposure……"***

Question 17.
*"Which of the following 3 statements best describes the situation regarding smoking in your child's **home?**…… Read all options to the interviewee before recording a response: Smoking is allowed in any common room of the home, smoking is limited to part of the house where the child rarely goes, there is no smoking inside at all?"*

Question 17a.
If answer to question 17 is "there is no smoking inside at all", then ask question 17a,
"Are there any exceptions to this situation?"
If respondent reports any exceptions, record "Yes". If no, skip to question 18.

Question 17b.
If answer to 17a is "Yes", then ask question17b.
"Under what circumstances are the exceptions allowed?"
Record a brief response as free text.

Question 18.
*"Which of the following 5 statements best describes the situation regarding smoking in your **car?**…. Read all options to the interviewee before recording a response: Smoking is usually or always allowed, smoking is sometimes allowed, smoking occurs in the car only when the child is not inside, there is no smoking inside the car"*
Record the response as it applies to the main automobile in which the baby rides. If family does not ride in a car (public transportation only or baby doesn't leave home), record response #1.

Question 18a and 18b. Responses questions to 18a and 18b are completed similarly to questions 17a and 17b.

Question 19.
'How often has the mother or primary caregiver smoked since your child was born?'
If speaking with the mother, please substitute "you" for "mother or primary caregiver". Record response based on occurrence of any smoking activity, regardless of where it takes place. Record "Never" if the mother or primary care giver has never smoked

anywhere since the baby was born, record "Daily" if she /he smokes daily in any location, and record "Occasionally" if response is neither "Never" nor "Daily".

Question 20.
"How many people in the child's home smoke?" |___|___| people
Record response based on occurrence of any smoking activity, regardless of where it takes place.

Script: *"The next questions are about your home and your babysitter's home or day care"*

Question 21.
"Approximately how many hours per week does your child spend at a babysitter's home or day care?" |___|___| hrs If 0 skip to question 22.
Record the number of hours that the baby spends outside his/her home, regardless of whether this is in the home of another parent, grandparent, or friend.

Question 21a.
If response to question 21 is greater than 0,
"How frequent is there smoke exposure at the babysitter or daycare?"
Record response based on occurrence of any smoking activity, regardless of where it takes place. Record never if there is no smoking allowed inside the babysitter or daycare provider's edifice in any location, record daily if smoking occurs inside the edifice daily in any location, and record occasionally if response is neither never nor daily.

Question 21b.
"How many children beside your baby are in the daycare?"
Record the average number of children less than 12 years of age who inhabited the babysitter or daycare over the past 2 weeks when the baby was present.

Question 22.
"How many children under 12 live in your house?" |___|___| children
Record number of children who spend more than 7 nights in the home over a two week period.

Question 23.
"Do you have any pets inside the home?"
Record "Yes" or "No"

Question 23a. If yes record,
"How many dogs? Cats? Do you have other pets? What kinds? How many?"

If respondent reports pets, please record the number of dogs and cats separately. Group all other pets together and record total number of pets that are neither a dog nor a cat.

Script: "*The last questions involve respiratory treatments that your baby may receive.....*"

Question 24.
"Has your child had RSV shots (palivizumab) to prevent Respiratory Syncytial Virus (Synagis, palivizumab, RSV shot)?"

Record respondent's answer, "Yes", "No" or "Don't know". If respondent does not recognize the treatment, record "Don't Know".

Question 25.
"Has your child had a flu shot?"

Record respondent's answer, "Yes", "No" or "Don't know". If respondent does not recognize the vaccine, record "Don't Know".

Question 26.
"Is your child on any oxygen therapy at home?"

Record respondent's answer, "Yes" or "No". If respondent does not know, the interviewer should prompt further by asking, "does your baby use any oxygen equipment, such as an oxygen tank, at home?"

Question 26a – 26c.
These questions can be answered using the following script.

If response to question 26 is "Yes",
"What device is used to provide the oxygen?.....Oxygen hood, nasal cannula or ventilator?"

Record response in checkbox provided.

If response to question 26 is "Yes", the interviewer should ask,
"*What percent oxygen does your baby use?"*

Record response as fraction inspired oxygen (FiO2) in the space adjacent to the oxygen delivery device. For example, room air (ambient air) is 21% oxygen, enter as FiO2 value of 0.21; pure oxygen is 100%, enter as FIO2 value of 1.0

If response to question 26 is either "nasal cannula" or "oxygen hood", interviewer asks,
"How many liters of oxygen does the baby receive?"

Record value as liters per minute (1cc is .001liters, 1/8 liter is 0.125 liters, ¼ liter is 0.25 liters, etc.)

MEDICATIONS

Script: *"The last two questions involve the medicines your child is taking for breathing problems....."*

Question 27.
"Since our last contact with you, w~~W~~hat medicines has your baby taken ~~over the past 6 months~~, including medicines delivered by a nebulizer or breathing machine?"

For this question, record all respiratory related medications. Record a written response in the table and later, after the interview, record the medication code from the table

below. Medications that do not appear on the list are unlikely to be used to treat respiratory conditions in this age group. Do not prompt for each medication in the medication list.

Chapter 8
18-22 Month Questionnaire

Introduction

The purpose of this questionnaire is to obtain an **interval** respiratory history and to identify a history of atopy that may increase the likelihood of symptomatic airway dysfunction. Questions are designed to ascertain the frequency and severity of wheezing and cough episodes and to assess the need for outpatient pulmonary care. In addition, risk factors obtained at the 1st interview will be confirmed. There are a total of ~~30~~ 34 questions, encompassing 27 questions from the ~~discharge, 6~~ month and 12 month questionnaires and 7 questions concerning respiratory infections and allergies.

This interview will be conducted at 18-22 months' corrected age, either by the local NICHD Follow Up Program (Option 1) or long distance from Rochester (Option 2), based on center preference.

Instructions for Completing the 18-22 Month Questionnaire (SUPF03)
Timing of the Interview:
The target window for this interview is between 18 and 22 months' corrected age. If for any reason the infant is enrolled into the Pulmonary Outcome Study at this time window or becomes available for a Pulmonary Outcomes Interview outside this window, the questionnaire should be administered, collecting an interval history from the time of NICU discharge or the most recent interview, whichever is most recent.

This interview should be administered by a certified study interviewer either by telephone prior to the regularly scheduled 18-22 month NICHD developmental follow-up clinic visit or face to face at the time of the visit.

Heading- Infant's Identification
The following information is included in the heading section of all patient specific data forms: Center, Site, Network Number, SUPPORT Follow-up Number, Birth Number and Mother's Initials **(optional).** This information should be completed on the first page of the interview and the SUPPORT Follow-up Number written on subsequent pages in case the completed form pages are separated.

8.1 Conducting the Interview

8.1.1 Initiating the interview:

The 18-22 month questionnaire is conducted in the same fashion as for the 6 and 12 month interviews. In addition to the 27 questions included in the 6 and 12 month questionnaires, the 18-22 month questionnaire includes 7 questions about allergies.

See Chapter 8 of the manual of procedures for directions to administer questions 1-~~28~~ 27 of the 18-22 month questionnaire. Directions for questions 28-34 begin here.

Script: "*The ~~last~~ next 2 questions regard ~~allergies~~ about respiratory infections.....*"

Question 28.
*"**During the past year**, for how many days has your child been unable to do his/her usual activities because of illnesses such as chest (not head) colds, bronchitis, asthma or pneumonia? 0-3 per year, 4-5 per year, 6-9 per year, more than 9 per year?"*

Question 29.
*"**During the past year**, ~~H~~how many head colds (common colds) **~~per year does~~has** your child ~~usually have~~had? Would you say...0-3 per year, 4-5 per year, 6-9 per year, more than 9 per year?"*

Script: "*The last questions regard allergies.....*"

Question 30.
*"Has your child **ever** had hay fever or any other condition that makes his/her nose runny, stuffy, or itchy **apart** from colds?"*
Record response, either "Yes" or "No". If respondent does not recognize the condition, record "No".

Question 31.
*"Has your child **ever** had allergies which cause nose, eye or lung problems?"*
Record response, either "Yes" or "No". If respondent does not recognize the condition, record "No".

Question 32.
*"Has your child **ever** been allergic to any food?"*
Record response, either "Yes" or "No". If respondent does not recognize the condition, record "No".

Question 33.
*"Has he/she **ever** been allergic to any medicine?"*
Record response, either "Yes" or "No". If respondent does not recognize the condition, record "No".

Question 34.
*"Has your child **ever** had eczema (allergic skin rash)?"*
Record response, either "Yes" or "No". If respondent does not recognize the condition, record "No".

Question 34a.
If Question 34 is "Yes",
"Was this diagnosed by a doctor?"
Record response, "Yes" or "No"

SAMPLE CONSENT FORMS

SAMPLE CONSENT FORM FOR PATIENTS ENROLLED IN SUPPORT

TITLE: SUPPORT Trial ~~Pulmonary~~ Breathing Outcomes Study- Follow-up Study of Infants Enrolled in the NICHD Neonatal Research Network SUPPORT Trial

PRINCIPAL INVESTIGATOR: Timothy P. Stevens, MD MPH

CO-PRINCIPAL INVESTIGATOR: Dale L. Phelps, MD

INTRODUCTION and BACKGROUND:
This consent form describes a research study and what you may expect if you decide to have your infant participate. You are encouraged to read this consent form carefully and to ask the person who presents it any questions you may have before making your decision whether or not to have your infant participate.

This form describes the known possible risks and benefits in the study. You are completely free to choose whether to participate.

Your infant is invited to be a part of this research project because (s)he is a premature baby who is a member of the National Institutes for Child Health and Human Development (NICHD) Neonatal Research Network SUPPORT Trial. As described in the SUPPORT Trial Consent that was discussed with you previously, the SUPPORT Trial is designed to find out more about treatment with CPAP (positive pressure applied with a face mask to help keep the lungs inflated) and learn the appropriate levels of oxygen saturation (oxygen levels in the blood) in premature babies. The SUPPORT Study will determine the effect of these treatments on your baby's respiratory and visual health prior to discharge from the Neonatal Intensive Care Unit (NICU).

However, we know that many babies born as early as your baby are at risk for breathing problems, especially wheezing and coughing during early childhood, after discharge from the NICU.

PURPOSE:
The purpose of Pulmonary Outcomes Study described here is to determine the effect of the SUPPORT Study treatment on your baby's respiratory health in early childhood, during the first 18-22 months after his/her expected delivery at full term.

PROCEDURES:
You and your infant's participation will begin with an interview before your infant is discharged from the hospital or at the time of your regular follow-up visit with the NICU Outpatient Clinic. At this interview we will ask you questions about your family, including questions about family history of breathing problems, and questions about your home, including things that may

increase your child's risk of breathing problems. You do not need to answer any questions that make you uncomfortable. The interview will take about 15 minutes.

We will continue to stay in touch with you and your infant by telephone or in person at one of your visits **((((Customize language here based on which option your center chose for administering the questionnaires))))** every 6 months over the next 18-22 months, a total of three times. At these times, we will ask questions about your child's breathing (especially wheezing and coughing), medication use, and visits to a Doctor, Emergency Room, or Hospital visits for treatment of breathing problems. We will also ask you several questions about your family and yourself. The entire call should take about 15 minutes of your time, less if your baby has had no breathing problems.

We will schedule the telephone calls at a time that is convenient for you. The telephone calls will occur when your infant is 6, 12, and 18 months after his/her expected delivery at full term.

The results from your baby's questionnaire will be combined with other infants from around the country. However, your baby's name will not be used.

We also ask your permission to contact your baby's Doctor to obtain their assessment of your baby's breathing and need for breathing treatments.

NUMBER OF PARTICIPANTS:
All babies who participate in the SUPPORT Trial will be offered the opportunity to participate in this study. There will be close to 1300 infants enrolled in the SUPPORT Trial. We hope that as many as possible will choose to participate in this study to help determine the long-term effect of the SUPPORT Study treatments. Approximately 40 babies will be enrolled locally.

RISKS AND DISCOMFORTS:
You may experience anxiety or psychological discomfort while completing these questionnaires and/or the interviews. You are free to choose not to answer any question for any reason.

BENEFITS:
The major benefit to you and your infant is that actual or potential breathing problems experienced by your baby could be identified early and brought to the attention of your baby's Doctor for treatment.

CONFIDENTIALITY OF RECORDS AND HIPAA AUTHORIZATION
While we will make every effort to keep information we learn about you private, this cannot be guaranteed. Other people may need to see the information. While they normally protect the privacy of the information, they may not be required to do so by law. Results of the research may be presented at meetings or in publications, but your name will never be used.

~~The federal Health Insurance Portability and Accountability Act (HIPAA) requires us to get your permission to use health information about you that we either create or use as part of the research. This permission is called an Authorization. We will use your child's research record, related information from your child's medical records, results of laboratory and other diagnostic tests obtained during his/her initial hospitalization, as well as the information and test results obtained during the telephone interviews of your baby's breathing.~~

We will use your child's health information to conduct the study, to monitor your child's respiratory status and to determine long term effects on breathing of the SUPPORT Study treatments. Health information is used to report results of research to sponsors and federal regulators. It may be audited to make sure we are following regulations, policies and study plans. If you have never received a copy of the Strong Health HIPAA Notice, please ask the investigator for one. To meet regulations or for reasons related to this research, the study investigator may share a copy of this consent form and records that identify you with the following people: The Department of Health and Human Services, the University of Rochester, the NICHD Neonatal Research Network and organizations (like RTI International) used by NICHD to manage studies.

If you decide to have your child take part, your Authorization for this study will not expire unless you cancel or revoke it. You can always cancel this Authorization by writing to the study investigator. If you cancel your Authorization, your child will be removed from the study. However, standard medical care and any other benefits to which you are otherwise entitled will not be affected. Canceling your Authorization only affects uses and sharing of information after the study investigator gets your written request. Information gathered before then may need to be used and given to others. For example, information gathered during your child's initial hospitalization will be sent to the NICHD Neonatal Research Network and to RTI International.

As stated in the section on Voluntary Participation below, you can also refuse to sign this consent/Authorization and not be part of the study. You can also tell us you want to leave the study at any time without canceling the Authorization. By signing this consent form, you give us permission to use and/or share your health information.

COSTS:
There is no cost to you to participate in the study.

CONTACT PERSONS:
For more information about this research, or if you believe your infant has suffered a research-related injury, please contact Timothy P. Stevens, MD MPH or Dale L. Phelps, MD (Principal Investigators) at (585) 275-2972. You can also reach them, or one of the other attending physicians, by asking the unit secretary in the NICU to page them.

If you have any questions about your rights as a research subject, you may contact the Human Subjects Protection Specialist at the University of Rochester Research Subjects Review Board at Box 315, 601 Elmwood Avenue, Rochester, NY 14642-8315. Telephone: (585) 276-0005, for long-distance you may call toll-free, (877) 449-4441.

VOLUNTARY PARTICIPATION:
Taking part in this study is entirely voluntary. You are free not to participate or to withdraw at any time, for whatever reason, without risking loss of present or future care you would otherwise expect to receive. In the event that you do withdraw from this study, the information you have already provided will be kept in a confidential manner.

SIGNATURES/ DATES:

I have read (or have had read to me) the contents of this permission form and have been

encouraged to ask questions. I have received answers to my questions. I give permission for my child to participate in this study. I will receive a signed copy of this form for my records and future reference.

SAMPLE CONSENT FORM FOR FUTURE SUPPORT PATIENTS

Consent to Act as a Research Subject

The Surfactant Positive Airway Pressure and Pulse Oximetry Trial in Extremely Low Birth Weight Infants

The SUPPORT Trial of the NICHD Neonatal Research Network

Neil Finer, MD, his associates, and the National Institutes for Child Health and Human Development (NICHD) Neonatal Research Network are conducting a research study to find out more about treatment with CPAP (positive pressure applied with a face mask to help keep the lungs inflated) and learn the appropriate levels of oxygen saturation (oxygen levels in the blood) in premature babies. You are being asked to allow your child to be in the study because there is a possibility he/she will be born between 16 and 12 weeks early (24-28 weeks gestational age).

The purposes of this trial are the following:
1) To compare infants who receive delivery room CPAP and who have strict guidelines for having a breathing tube placed with infants who have the tube placed and surfactant (a liquid which helps babies with immature lungs breath easier by helping keep their lungs from collapsing) given in the delivery room.
2) To compare low range (85-89%) oxygen saturation levels with high range (91-95%) levels to determine if a lower range results in decreased ROP (Retinopathy of Prematurity, an eye disease that may result in impairment of vision or even blindness, which may be caused by excessive levels of oxygen.)

Duration of the Study: We expect to include about 1300 babies in the study from all the NICHD Neonatal Research Network hospitals over a two-year period.

The use of CPAP and Intubation/Surfactant are both treatments currently used in the delivery room at UCSD. The decision as to which to use is currently made by the physician attending the delivery.

The oxygen level currently used in the NICU at UCSD is between 85% and 95%. Both treatment groups (85-89% and 91-95%) fall within that range. The study will attempt to keep babies in one of these two smaller ranges.

If you agree to allow your child to be in this study, the following will happen to your child: Prior to delivery, and after your permission, your baby will be randomized (chosen by chance like the flip of a coin) to one of two lung treatment strategies. The treatments are as follows:
1) CPAP in the delivery room immediately after birth and continuing in the NICU, or
2) The placement of a tube in his/her trachea (windpipe) in the delivery room followed by surfactant administration and ventilation (breathing for the baby using a machine).

In addition to being randomly assigned to one of the two groups described above, your baby will be randomized to a High reading or Low reading oximeter (a monitor that displays how

much oxygen is in the blood). The oximeters (oxygen monitors) used in this trial are FDA approved oximeters which have been modified for research purposes. This modification makes the monitors show a value which is either slightly higher or slightly lower than the true oxygen level when values are between 85 and 95%. Outside those ranges, the oximeter works the same as the standard of care device.

Which group your baby is randomized to will not be known to the nurse taking care of your baby, or his/her physician. Only the study coordinator will know which group your baby is in. Within the range of oxygen which we normally keep babies in, your baby will either be on the high end of normal or the low end of normal. He/she will remain on this device until he/she reaches 36 weeks adjusted age. (e. g. 24 wks gestation plus 12 weeks of age = 36 weeks adjusted age). Other care will be conducted as normal during his/her participation in the study.

We will continue to stay in touch with you and your infant by telephone or in person at one of your visits ((((Customize language here based on which option your center chose for administering the questionnaires)))) every 6 months over the next 18-22 months, a total of three times. At these times, we will ask questions about your child's breathing (especially wheezing and coughing), medication use, and visits to a Doctor, Emergency Room, or Hospital for treatment of breathing problems. We will also ask you several questions about your family and yourself. The entire call should take about 15 minutes of your time, less if your baby has had no breathing problems.

We will schedule the telephone calls at a time that is convenient for you. The telephone calls will occur when your infant is 6, 12, and 18 months after his/her expected delivery at full term.

The results from your baby's questionnaire will be combined with other infants from around the country. However, your baby's name will not be used.

Participation in this study may involve some added risks or discomforts. Because all of the treatments proposed in this study are standard of care, there is no predictable increase in risk for your baby. Infants randomized to the CPAP group may, at some point in their care, require intubation and assisted ventilation (methods to help them breathe). If the attending physician deems this necessary, participation in the study will not affect this decision. Some unknown risks may be learned during the study. If these occur, you will be informed by the study personnel. The only other risk of this study is the risk to confidentiality. Every effort will be made to keep your child's medical record confidential. There will be no name or other patient identification in any study report that may be published after the study is completed. Measures taken to protect you and your baby's identity are described in the confidentiality section of this document.

There may be benefits to your child directly, including a possible decrease in chronic lung disease (need for extra oxygen near discharge) **or wheezing** <u>or cough</u> **in the first 2 years** and/or a decrease in the need for eye surgery as a result of exposure to oxygen. Because we do not know in advance the actual strategies chosen for your child, or which of the treatment strategies is the most effective, it is also possible that your baby will receive no direct benefit. The knowledge learned from this study may help us treat babies in the future. However, as noted above, each of the 4 possible combinations of treatments is considered by some units to represent their desired approach.

If your child is injured as a direct result of participation in this research, the University of California will provide any medical care your child needs to treat those injuries. The University will not provide any other form of compensation to you if your child is injured. You may call the UCSD Human Research Protections Program office at (858) 455-5050 for more information about this, or to inquire about your rights as a research subject, or to report research-related problems.

_____ has explained this study to you and answered your questions. If you have other questions or research-related problems, you may reach Wade Rich, the Study Coordinator, or Renee Bridge, the Research Nurse, at 619-543-6560. You may contact the principal investigator Dr. Neil Finer at 619-543-3794

As an alternative to participation in this study you may decide to have your baby's doctor decide which treatment your baby will receive. If you decide not to include your child in this study, none of his/her medical information will be included in the study data. Participation in research is entirely voluntary. You may refuse to participate or withdraw at any time without jeopardy to the medical care your child will receive at this institution of other loss of benefits to which your child is entitled. If you withdraw your child from the study, the attending physician will decide whether to maintain current treatment or change it, based on your child's needs at the time of the decision. Data collection for research purposes will stop at that time.

Clinical information will be collected from your baby's chart by study personnel at UCSD. Information will be labeled with a code number. Coded information will be sent to the NICHD Neonatal Network's Data Coordinating Center at RTI International in Research Triangle Park, North Carolina. The study log linking the code number with your baby's identity will be kept under lock and key at UCSD. Information directly identifying your baby will not leave UCSD. Research records will be kept confidential to the extent provided by law.

You may withdraw your child from the study for any reason. In addition, the study doctors may decide to withdraw your child if they feel it is in his/her best interest to do so. You have received a copy of this consent document to keep and the Experimental Subject's Bill of Rights.

You agree to have your child participate.

Subject: FW: SUPPORT visits by Dr.Sayre

Rose, Neil,

I was going to send this to sites and Maribeth. Can you review? Thanks.

Coordinators at more than one site have asked me why we have
scheduled visits from Maribeth Sayre at Masimo for Support centers.
Please be advised that
these visits are being planned, carried out, and paid for by Masimo.
The are not related to the study in any way. If you need help with your
oximeters, you may
call Maribeth as you always have and she will assist you as best she
can. You may treat any visits initiated by Masimo as a sales call, and
treat them as you would any other visit from a company representative.
You should not, at the request of Dr. Higgins, discuss patient
information or study data with Dr. Sayre.

Thank you,
Wade Rich

Subject: RE: SUPPORT visits by Dr.Sayre

Hi Rose

I have no knowledge of this and there should not be any Masimo visits for SUPPORT. The equipment is bought and paid for, this is not an FDA trial, and they have no role at the sites. In addition I do not want them interfering with the study oximeters. I will ask Wade to call Maribeth and Masimo and clarify.

I am out of town for the next 8 days, but I will try to stay tuned to my email. I'm not sure if I will be able to do this. If necessary I will call her myself.

Neil

Subject: SUPPORT visits by Dr.Sayre

Rose,

Just curious as to the nature of the SUPPORT Study visits that Dr. Maribeth Sayre is scheduling. Is this just a PR meet and greet and tour of the sites at our center? She did mention that she wanted to know if we had any problems or suggestions --- and I assume that only deals with the Masimo equipment, not other study issues. What information is she privy to? A few guidelines would be helpful.

Thank you.

Nancy P.

Subject: RE: SUPPORT visits by Dr.Sayre

Rose,

Correct, she is the Director of Medical Affairs for Masimo. I wanted to be sure that I understood the nature of her visit ("meet and greet" but no "show and tell"). Since we had received no official word that there would be a monitoring visit, I was a bit surprised when I received her telephone call and began wondering about what my obligations were to her. Thank you for the information.....it will help me in scheduling her visit.

Hi Nancy,
It is my understanding that Dr. Sayre is with Massimo, correct? If so, she should discuss only the equipment. No patient information or study data can be shared with her.

Thanks for asking!

Rose,

Just curious as to the nature of the SUPPORT Study visits that Dr. Maribeth Sayre is scheduling. Is this just a PR meet and greet and tour of the sites at our center? She did mention that she wanted to know if we had any problems or suggestions --- and I assume that only deals with the Masimo equipment, not other study issues. What information is she privy to? A few guidelines would be helpful.

Thank you.

SUPPORT TRIAL COMMENTS

NICU Discharge-Baseline Interview

p.1 Many parents may not understand what is meant by wheezing. Will the audiotape used for subsequent interviews be utilized?

Also, in section describing contents of diary may want to indicate that subsequent contact may be by phone or face-to-face interview.

p.3 14a. Don't know should be option 3

p.4 Under Father. Should change "Does she have bronchitis..." to Does *he* have bronchitis

Is there a page 5?

p. 6 Table Paternal Grandfather repeated. Need to change to paternal grandmother.

p.7 The parent or caregiver who completed the initial interview is requested to complete this interview. What if not primary caregiver?

Some of our families may not remember agreeing to the follow-up component. May need to remind them what the study entails. Would also be

a good idea to review follow-up at time of discharge for all surviving patients.

p. 9 It may be helpful to explain what is meant by wheezing/play audiotape prior to Q6.

Question 9. What if they answer 2 or 3 to 9 and then 1 to 9a. Or subsequently change their response to 9 after hearing audiotape. What response should be recorded? Initial or subsequent?

p. 11 Question 12. "...change for..." should be change *your *Question 13 Will miss those patients with wheezing/ bronchospasm whose physicians diagnose with exacerbation of BPD
*

*p.14 Prednisolone not included as a systemic steroid

p.15 target window for interview should be 18-22 months not 8-22

p.17 Again, may want to define what is meant by wheezing prior to question 6

p.20 Question 16a. Does this question refer to past 6 months only or in total. May need to clarify for parent.

p.21 Intro to Question 27 states "last 2 questions" However, there are more that 2 questions.

p.22 Question 29. Difficult to say how many colds per year usually as <2y.

Jon
The SUPPORT growth secondary group had a call today. The steering committee has approved the protocol to go forward without dollars at this point in time. There will be a vote in April 2006 for the financial part of the study. The data collection has been markedly decreased. We have a one page form which will be distributed within the next week or two.

Thanks

Subject: SUPPORT GROWTH SECONDARY

HI,
I need a vote from the PI's regarding the SUPPORT GROWTH SECONDARY presented by Dr. Duara last week at the steering committee meeting.

Please indicate your preference:

1. Yes – this needs to go forward without additional funding and should start now
2. Yes – this needs to go forward and we should commit funds from the 2006 budget (this will impact the possibility of other protocols being instituted)
3. No – this needs to wait for the next budget period with reassessment in April 2006
4. No – this should not be done

I have attached the protocol.
Send me your vote by September 30.

Thanks
Rose

You are absolutely correct. This situation arose over the fact that home visits are encouraged for non-compliant families, and may be made by a psychometrist or psychologist with a coordinator, nurse etc. and the physician is not always a part of the home-visit assessment team. Another example is when the physician goes on a home visit with a severely handicapped child (example spastic quad, blind, deaf etc) and attributes a 49 to the Bayley. Most sites do not permit a single person to do home visits.That individual or a second clinic professional can be trained to appropriately ask the questions on the NFO5. It is an issue currently at Indiana since the IRB states that it must specifically stipulate in the manual who the person (s) are who are qualified to do the specific component of the assessment. Only the trained professional who saw the child would obviously fill out the form. There is a lot of cross training at sites for efficiency purposes, which is a good idea and contributes to improved compliance with the protocol. We can discuss this further tomorrow with the group. It may be at some sites such as yours that a physician goes on all home visits and it is a non-issue.

Subject: RE: Reminder: SUPPORT Follow-up Conf Call - Tues Nov 1 at 2pmEST

I'm not clear on exactly what change is being proposed re who can fill out the NF05. Sounds like some consideration is being given to extending this beyond the group of interrator-certified/trained medical practitioners. First of all, given how much discussion/debate we have had among ourselves about where/how to draw the line on some of these critical assessment items, I think we should be very cautious about delegating these skills to others with less appreciation/experience in neuromotor exam/assessment. Secondly, I don't think we can have one person assess some of the items and another draw the conclusions.

>>> "Betty Vohr" <BVohr@WIHRI.org> 10/31/05 3:24 PM >>>
Greetings all. I am ccing you on emails that were initiated by Anna Dusick. It involves a minor change in the manual stipulating who can fill ou the NFO5. I hope that we can approve this at the end of the conference call for Support. The basic request is to describe and expand who can fill this out. Some IRBs are very directive in this regard.

I think we need to remember that their are tremendous site differences in how this is carried out.

From: Dusick, Anna M. [mailto:adusick@iupui.edu]
Sent: Monday, October 31, 2005 2:57 PM
To: Betty Vohr
Subject: RE: NFO5 and the manual

This is interesting as the judgement parts (GMFS, hand and UE coordination) may require some training that a psychologist/psychometrist has. In some cases, the study nurse coordinator will not have the skills for the GMFS or the hand and UE coordination items. I was hoping to get away from that discussion and to keep the data entry tight. Also, it does not quite fit with my rationale, as an LPN for example, may not have the skills for hand function assessment. I added it anyway. See what you think.

I would keep the term Study nurse, coordinator etc. so we do not get into human subjects violations and not use "other trained clinical staff person". We cannot, for example "deputize" another staff person for the day we are away.

What are your thoughts on asterisking the items on the NF05 that the non-Neuroexaminer can complete? In the case of an audit, the study police would look for wrongly entered items not permitted by the protocol, and we want to keep the integrity of the data. As PI it would be each of our responsibility to be sure just the permitted parts of the NF05 are completed by a non-neuro examiner. This may be more than some want to do. For example, even if obvious, the Study personnel cannot answer the CP diagnosis unless a neuro-examiner.

Dear Follow-up PI's,

Please note that a conference call to review the SUPPORT Follow-up study documents (Manual of Operations, forms, and respiratory diary previously distributed to you) will be held tomorrow - Tuesday, November 1 from 2 - 3pm EST. If you are not able to join this call please submit your comments via email or ask your follow-up coordinator to serve as your proxy. We look forward to hearing your comments on the study documents.

Also, Dr. Shankaran would like to take the first 10-15 minutes of the call to provide an update on the aEEG Follow-up. Please review the one form that will change for the aEEG follow-up, Form 9 - the Bayley Scales Summary Score Sheet, which is attached. The rest of the forms will be the same as those used for the Hypothermia follow-up. The Infant Examination Form (Form 05) will not change but clarifications in the MOO have been made to improve data collection on hearing impairment. Below is the relevant section of the aEEG Follow-up MOO:

b. Hearing impaired:

Code '1' if no apparent functional impairment at the time of this assessment.

Code '2' if impairment at the time of this assessment.

Where impairment is defined as any restriction or lack of ability to perform within the range considered as normal or if there is chronic otitis media with associated delayed speech skills.

1) If Impairment (2), hearing aid requirement:

Code '0' if no hearing aid has been prescribed by a hearing specialist.

Code '1' if hearing aid has been prescribed by a hearing specialist for the right ear only.

Code '2' if hearing aid has been prescribed by a hearing specialist for the left ear only.

Code '3' if hearing aid has been prescribed by a hearing specialist for both ears.

The aEEG Follow-up MOO and forms will be distributed to you in the next week.

Subject: RE: MRI Secondary for SUPORT
Date: Monday, October 31, 2005 11:12:39 AM

Hi Mike and Susan
The use of the baby bean bag seems to work very well. Our center has a very active MR program and getting to the magnet and taking up time is a prime issue. I would recommend that you consider this type of device. We will be doing 3 more infant today and tomorrow, and if this works, I would probably suggest that we send out some information about it with pictures. I'll keep you informed.
I agree with Susan, but would suggest that your IRB let the parents judge the benefit vs risk in view of the information that can be oobtained.

Sent: Friday, October 28, 2005 6:39 PM
To: Michael O`Shea
Cc: neil finer; higginsr@mail.nih.gov
Subject: Re: MRI Secondary for SUPORT

Mike,

Thank you for your note.

1) First, I want to make sure that the concept of "congenital infection" is clear in the secondary - I am specifically talking about TORCH infections/HIV/syphylis, not something like GBS or E.Coli. I was really only trying to eliminate a potentially powerfully confounding variable. My suggestion would be to state that any head imaging would only be used in the STUDY if TORCH infections are not suspected. I think that is pretty much what you suggested below.

2) There is no doubt that white matter injury can be better visualized on MRI than US. The follow-on point is that neuromotor outcome is linked to white matter development/injury and that this is a major issue in neurodevelopmental outcome in the preterm infant. Your recent review (with Serena Counsell and Professor Dammann) is wonderful and quite comprehensive, and I think you spell out well the limitations and positive points of the few studies that have been published of head-to-head comparisons of MRI and US in predicting outcome. If a counterargument from your colleagues includes the work of Linda de Vries - which is incredibly great work - you might point out that Dr. deVries did WEEKLY ultrasounds to get the good results she got. You might also point to the work of Wilson-Costello and recently of Abbott Laptook underscoring the limitations of ultrasound alone with respect to explaining adverse neurodevelopmental outcomes among premies.

Bottom line, if YOU can't convince your colleagues and IRB with your considerable debating powers and knowledge, I am not sure it can be done. If they can't be convinced, I agree that the best option is to indicate that two attempts will be made without sedation, then forget it.

By the way, Wade Rich (UCSD's wonderful coordinator) and I have become best friends by email - he has managed to get MRI's of two SUPPORT patients without sedation - and their site had not previously used that technique, so it was new. Maybe the sedation won't be needed?? Hopefully...

Susan

> Susan and Neil,
>
> Our IRB has raised a couple of questions about the MRI Secondary and I'm hoping you can help with the answers.
>
> 1) The main SUPPORT Trial does not have as one of its exclusion criteria congenital infection, whereas the secondary MRI study lists congenital infection as an exclusion criteria. If a center desires, as we do, to have a single consent form (similar to the Stanford consent form which Susan distributed as a template) the discrepancy between the exclusion criteria for the primary and secondary studies raises a problem. Specifically, if a child is enrolled in SUPPORT and then after delivery the diagnosis is made of a congenital infection, it would seem that the child becomes ineligible for the secondary. If this correct, then then consent form needs to state that the MRI will be done only on those infants who are not found to have a congenital infection, right?
>
> 2) In the past our IRB has not approved the use of conscious sedation for research studies unless there is a prospect of benefit to the child. While I understand that some neonatologists and radiologists feel that there is clinical benefit to an MRI, this is a difficult position to adopt here where we obtain both an early and a late cranial ultrasound and so the issue becomes not whether the MRI is beneficial but whether it is beneficial in a child who already has information from two ultrasounds. I am not convinced that this is the case nor are my colleagues. That presents several options:
>
> -- Perhaps you can provide a convincing argument that I can use to convince my colleagues and the IRB that the MRI holds the potential for benefit

Subject: RE: infant enrolled at less than 401 grams
Date: Monday, October 31, 2005 8:39:15 AM

Let us keep this baby in the study. For future reference, we can send out a memo to the sites that only GDB babies should be considered for inclusion in the Candidiasis study.

Thanks

Abhik

Cc: Das, Abhik; 'Higgins, Rosemary (NIH/NICHD)'; Poole, W. Kenneth
Subject: RE: infant enrolled at less than 401 grams

It was our intent to have GDB babies in the study because the GDB database and candida database could be reconcilled for some of the information for the candida study. For example some potential morbidities (such as ROP) rely on the GDB. My concern is that when we developed the CRFs for the candida study, the candida steering committee consistently thought (and said) 'we will have GDB' when deciding on capture elements.

However, the crucial elements (blood results and CAO3-CA06) will not be missing for this infant. So my thinking is

1) This baby should stay in the study for reasons Dale has outlined
2) We should remind coordinators that infants should be enrolled in GDB to get into Candida study.

Subject RE: infant enrolled at less than 401 grams

Hi all,

I think because the protocol specifies infants of <1000g

And
The infant's mother has been approached and already has consented to be in the study, that we should include this infant.
(There is no additional cost because the GDB data are already being completed because the infant was enrolled in the SUPPORT study.)

I could propose for the future that an infant of <1000g BW who is also less than 401 grams could also be enrolled in the Candidiasis study IF she/he had been enrolled in SUPPORT. (this will make them 24 weeks or older)

If, however, the RTI database is going to have problems because the BW is outside the parameters permitted for analyses, I could understand why the future plan would be not to include infants of less than 401g.

Also, if the majority vote is that this infant not be in Candidiasis, I would understand. Just let us know so that we don't collect samples on the baby.

Dale

Subject: RE: infant enrolled at less than 401 grams

For the sake of consistency I dont think any data from this baby should be used in analyses for this study. So, I would recommend stopping the data collection unless it is not prudent for the site to do that at this stage (since they have already approached and consented the mother about this study).

Thanks

Abhik

Danny

I had spoken to Abhik and Ken about this. The baby was included in SUPPORT and therefore GDB forms were filled out due to SUPPORT. This was addressed up front in SUPPORT, but never discussed in candida with respect to infants < 401 grams. Since we were almost close to halfway on candida, we thought that these infants should not be included in the trial (as they have not been recruited thus far). This is a fluke as the child was enrolled in SUPPORT. As far as continuing to obtain samples, I would defer to the data center.

infant enrolled at less than 401 grams

Hi Danny,
We have a baby that we put in the GDB at less than 401 grams because the baby was enrolled in SUPPORT. Because she was in the GDB, we enrolled her in Candidiasis. Last Thursday, Rose told us on the coordinator's call that infants less than 401 are not eligible for Candidiasis. What should we do with this baby? Should we continue to obtain samples, or stop?

Subject: Reminder: SUPPORT Follow-up Conf Call - Tues Nov 1 at 2pm EST
Date: Monday, October 31, 2005 8:02:17 AM
Attachments: aEEGF09 BayleyScales jn.DOC

Dear Follow-up PI's,

Please note that a conference call to review the SUPPORT Follow-up study documents (Manual of Operations, forms, and respiratory diary previously distributed to you) will be held tomorrow - **Tuesday, November 1 from 2 - 3pm EST.** If you are not able to join this call please submit your comments via email or ask your follow-up coordinator to serve as your proxy. We look forward to hearing your comments on the study documents.

Also, Dr. Shankaran would like to take the first 10-15 minutes of the call to provide an update on the aEEG Follow-up. Please review the one form that will change for the aEEG follow-up, Form 9 - the Bayley Scales Summary Score Sheet, which is attached. The rest of the forms will be the same as those used for the Hypothermia follow-up. The Infant Examination Form (Form 05) will not change but clarifications in the MOO have been made to improve data collection on hearing impairment. Below is the relevant section of the aEEG Follow-up MOO:

b. Hearing impaired:

Code '1' if no apparent functional impairment at the time of this assessment.
Code '2' if impairment at the time of this assessment.

Where impairment is defined as any restriction or lack of ability to perform within the range considered as normal or if there is chronic otitis media with associated delayed speech skills.

1) If Impairment (2), hearing aid requirement:

Code '0' if no hearing aid has been prescribed by a hearing specialist.
Code '1' if hearing aid has been prescribed by a hearing specialist for the right ear only.
Code '2' if hearing aid has been prescribed by a hearing specialist for the left ear only.
Code '3' if hearing aid has been prescribed by a hearing specialist for both ears.

The aEEG Follow-up MOO and forms will be distributed to you in the next week.

The call-in information is as follows:

Seetha,
We have had extreme difficulties in finding a day that maximizes participation for this call. Nov 1 seemed to work for the highest number of people. Attached is the revised aEEGF09 (Bayley Scales Summary Score Sheet) based on my discussion with Becky. Please let me know if I have accurately captured the revisions and I will send it out before the call on Tuesday.

You mention sending the group the Infant Examination Form (aEEGF05) as well but we did not make changes to the form, we just made some clarifications in the MOO. Below is the relevant section of the form and the corresponding description in the MOO. Will it be sufficient to simply send the text below rather than the entire form since changes will not be made to the form?

b. Hearing impaired: ___

1 = No apparent functional impairment 2 = Impairment

1) If impairment (2), hearing aid requirement: ___

0 = None 1 = Right only 2 = Left only 3 = Both

b. Hearing impaired:

Code '1' if no apparent functional impairment at the time of this assessment.
Code '2' if impairment at the time of this assessment.

Where impairment is defined as any restriction or lack of ability to perform within the range considered as normal or if there is chronic otitis media with associated delayed speech skills.

1) If Impairment (2), hearing aid requirement:

Code '0' if no hearing aid has been prescribed by a hearing specialist.
Code '1' if hearing aid has been prescribed by a hearing specialist for the right ear only.
Code '2' if hearing aid has been prescribed by a hearing specialist for the left ear only.
Code '3' if hearing aid has been prescribed by a hearing specialist for both ears.

Jamie
Nov 1 is a very bad day for me but that is the only day available , right? I need to speak to all the FU PI's so this is the only opportunity so I will have to attend

I would like to start at beginning of the call (2 PM) and briefly do the following

a) Update on aEEG FU forms and manual

b) Changes from the Hypothermia trial forms: 1) hearing assessment clarification and 2) Bayley summary forms---I would like you to send the 2 forms that we are discussing (the hearing assessment and the Bayley summary form) to all so they can see what I am talking about. Becky has gone over this with you

c) Changes to Extended FU study as discussed on last conference call

d) need to get data on SES/maternal education/ on all subjects

Anything else, Becky or Rose?

Thanks
SS

Subject: SUPPORT GROWTH SECONDARY

HI,

I need a vote from the PI's regarding the SUPPORT GROWTH SECONDARY presented by Dr. Duara last week at the steering committee meeting.

Please indicate your preference:

1. Yes – this needs to go forward without additional funding and should start now
2. Yes – this needs to go forward and we should commit funds from the 2006 budget (this will impact the possibility of other protocols being instituted)
3. No – this needs to wait for the next budget period with reassessment in April 2006
4. No – this should not be done

I have attached the protocol.

Send me your vote by September 30.

Thanks

Rose

Subject: SUPPORT Pt question

Hi Wade,
I have a few questions for you regarding a recent enrollee into the SUPPORT trial here at UC. here's the situation: Infant (b) (6) was born (b) (6) at 27 and 2/7 weeks gestation, and randomized into the control arm of the study. He required extensive active resuscitation (including chest compressions, 7 rounds of epi, multiple round of bicarb) over his first 40 minutes of life. (I have already submitted that resuscitation as an AE, btw). On the way back to the NICU, the team stopped with the baby in mom's recovery room for (b) (6). by the time they got the baby back, and retaped the ETT, then gave him surfactant (since it is policy here to give it back in the NICU), he was about 1.5 hours old. (so I have written that up as protocol deviation #1.)
On DOL #3 (b) (6), he met extubation criteria. However, he has not yet been extubated because he has no respiratory effort of his own. He has generalized hypotonia, little to no spontaneous movement, weak reponses to noxious stimuli, and absent gag reflex. He had a brief trial of CPAP via ETT, which he quickly failed. The suspected diagnosis is HIE at this point, though it has not been confirmed. (he has some mild dysmorphic features, and the possible diagnosis of congenital muscular dystrophy has been suggested by the neuro team.)
So, sorry to be so detailed, but I wanted to paint the complete picture for you. What is the best way to document this. Should I write up a second deviation? And if so, should I code it as #10 "other"? (I don't see it specifically listed in the previous 9 types of deviations.) Or should I capture it somewhere else as "extenuating circumstances" that have prevented his extubation? In the MOP on page 5-4 it states "Failure to attempt to extubate an infant meeting all of the above criteria will be recorded as a study protocol deviation unless extenuating circumstances are noted."
Your input would be greatly appreciated!
thanks, kate bridges

Post-natal Growth of Infants Enrolled in the NICHD Neonatal Network Oxygen Saturation (SUPPORT) Study: A Proposed Secondary Study

Cristina Navarrete MD, and Shahnaz Duara MD
University of Miami Miller School of Medicine, Miami, FL.

Abstract:

Post-natal growth restriction is a major problem in preterm infants. Perturbations in oxygenation are recognized to influence post-natal growth; hypoxic conditions can directly impair growth and hyperoxic conditions predispose infants to BPD, which in turn has been linked to poor growth. The NICHD Neonatal Network is conducting a prospective trial of preterm infants randomized to two levels of baseline oxygen saturations. The effect of baseline saturations on pulmonary morbidity and ROP are the primary outcome measures. With respect to post-natal growth, there is a paucity of data relating alterations in baseline oxygen saturation and/or frequent deviations above or below the baseline to growth outcomes. We propose a secondary study to quantify short-term growth velocity in-hospital and long-term growth at 18-22 months of corrected age for infants enrolled in the SUPPORT Trial in relationship to oxygen saturation.

A. Hypothesis to be tested

Primary:

1. Infants in the low oxygen saturation group (85-89%) will have better in-hospital and long-term (18-22 months corrected age) growth.

2. Trajectories of growth in hospital will be better for infants in the low oxygen saturation group.

Secondary:

1. Growth will be greater in infants who spend > 50% of the time with daily median oxygen saturation between 85% -95% while on supplemental oxygen, independent of randomization to low or high oxygen saturation.

2. Infants with BPD will have poorer in-hospital and long-term growth than infants without BPD, independent of the saturation randomization arm.

3. Better long-term growth will be positively related to neuro-developmental outcome, independent of the saturation randomization arm.

B. Specific Aims:

1. To determine anthropometric measurements (wt, HC, length) in infants randomized to low and high oxygen saturation arms, from birth to hospital discharge and again at 18-22 months corrected age.
2. To determine nutritional intake (parenteral and enteral) during hospital stay.
3. To determine the percentage of infants with growth <10 percentile at 36 weeks PMA or discharge, whichever comes first.
4. To determine the percentage of infants with growth <10 percentile at 18-22 months corrected age.
5. To determine growth in relation to the proportion of time spent with oxygen saturation
    a. <85% and >95%
    b. 85%-95%
6. To determine growth in relation to infants' median oxygen saturation while in supplemental oxygen
    a. median oxygen saturation > 95%
    b. median oxygen saturation 85% - 95%
    c. median oxygen saturation < 85%
7. To relate incidence of BPD in low and high saturation arms to growth.
8. To determine in-hospital growth velocity/trajectory in low and high saturation arms.
9. To determine long-term growth velocity/trajectory, from hospital discharge to follow up at 18-22 months corrected age in low and high saturation arms.
10. To relate neuro-developmental outcome at 18-22 months corrected age to long-term growth in low and high saturation arms.

Rationale:

The SUPPORT Trial will randomize infants to two ranges of SpO2 in order to test the hypothesis that use of a lower SpO2 range will result in an increase in survival of preterm infants without the occurrence of threshold retinopathy of prematurity and/or the need for surgical intervention. Retrospective cohort data from several units in the U.K., with different oxygen supplementation policies, revealed poorer growth patterns in the preterm infants exposed to higher oxygen saturations for the duration of oxygen exposure (Tin 2001). Conversely, observational data of infants with established BPD show better growth with home oxygen support (Groothius 1987), and two recent RCT of different target saturations in older oxygen-dependent premature infants showed no difference in short or long-term growth outcomes (STOP-ROP 2000, BOOST Trial 2003). There are no RCT data evaluating the short or long-term growth impact of different SpO2 strategies with supplemental oxygen use in a birth cohort of extremely preterm infants. Therefore, this study provides an opportunity for us to

obtain critically needed growth information on premature infants who are exposed from birth to different target oxygen saturation strategies.

Background

Improvements in antenatal care, respiratory support and nutrition have contributed to increased survival of ELBW infants. As the number of survivors increase, the long term outcome of these infants becomes more important. Lemons et al described growth failure or weight <10th percentile at 36 weeks postmenstrual age in 97% of ELBW infants surviving to discharge. Some morbidities in adulthood are linked to growth during the early post-natal period (Singhal 2004) and make adequacy of growth in this population of heightened interest.

Instead of following intra-uterine growth curves of age matched fetuses, VLBW infants exhibit wide-spread post-natal growth retardation (Cooke 2004), losing ground during the first weeks of life (Berry 1997). To resume growth post-natally, nutrition is of paramount importance; however, other factors such as severity of illness and perhaps oxygenation also play a role. Observational studies of infants with BPD showed poor post-natal growth when infants were sent home without oxygen supplementation (Markestad 1981).

Although preterm infants without lung disease attain oxygen saturations >95%, artificial attempts to keep arterial oxygenation at a "physiological" level may not be beneficial to growth, the lung or retina (Tin 2001). Animal studies have shown that newborn mammals (mice, rats, guinea pigs) develop poor growth with chronic hypoxia and that blunted body growth is directly proportional to the profundity of the exposure to chronic hypoxia (Mortola 1990). Chronic hypoxemia has also been suggested as the cause of poor growth in patients with cyanotic congenital heart disease (Dundar 2000). When home oxygen supplementation was discontinued inappropriately by parents in a cohort of VLBW infants with BPD, there was a deceleration in the rate of weight gain, which improved when oxygen supplementation was resumed (Groothius 1987). Hudak et al in 1989 observed that ELBW infants with CLD who went home on oxygen supplementation had good catch-up growth at 19 months. Taken collectively, these data suggest that hypoxic conditions affect growth negatively and supplementing oxygen may improve growth.

The optimal level of oxygen saturation to promote post-natal growth is unknown. Most of the available human data is limited to oxygen supplementation of infants who are oxygen dependent or have BPD. Baraldi et al demonstrated that discharged infants with BPD, who were kept on supplemental oxygen to keep saturations above 94%, had progressive but poor weight gain (stayed below 3rd percentile) at 9 months corrected age follow-up. In infants with BPD whose oxygen supplementation was intentionally discontinued, the subset who exhibited episodes of desaturations below 88-91% had a significant decline in the rate of weight gain as compared to those who maintained saturations above 92% (Moyer-Mileur 1996). Conversely, when two different oxygen saturation control policies (high: 88-98% and low: 70-90%) were retrospectively reviewed in <28

week gestation infants, the infants being cared for in the high oxygen saturation policy units were more likely to weigh less than the 3rd percentile at discharge (45% vs. 17%, Tin 2001). The infants assigned to the high oxygen saturation limits were also more likely to have BPD and ROP.

Recently, the BOOST Trial demonstrated that randomizing infants born <30 weeks gestation who were still on oxygen at 32 weeks postmenstrual age either to standard saturations (91-94%) or to high saturations (95-98%) produced no significant difference in growth at 12 months corrected age. This study, while randomizing infants to two different levels of saturations (conventional and high), only enrolled infants if they were still on oxygen supplementation at 32 weeks PMA and used higher limits than planned by SUPPORT. Our proposal is novel in that randomization to the two oxygen strategies begins at birth and continues for as long as the infants are in supplemental oxygen - by implementing this secondary we will be able to determine the impact of these strategies on short and long-term growth.

Methods:

Anthropometric Measures – at birth, postnatal days 7, 14, 21, and 28 days, 32 w PMA and 36 w PMA or discharge (wt, length, HC)

1. Weight - using standard digital electronic scales (c/o infant's nurse)
2. Length - using the Premie Length Board (average of two values, c/o research staff)
3. Head circumference - using paper measurement tape (average of c/o research staff)

Clinical Data-

1. Date when infant regains birth weight
2. Date of first enteral feed
3. Date of full enteral feeds (enteral > 120ml/kg/d)
4. Total number of days on parenteral nutrition
5. 24 h intake 'snapshots' (Parenteral, Enteral) – postnatal days 7, 14, 21, and 28, 32w PMA, 36w PMA or discharge (whichever comes first)
6. Presence of BPD

Intervention Data –

1. Duration of time spent in target saturation ranges of interest (Already part of SUPPORT‡)
2. Median values for unmasked oxygen saturation while still on supplemental oxygen therapy‡
3. Highest daily FiO_2‡
4. Duration of supplemental oxygen exposure‡
5. Documentation of post-discharge oxygen use

Follow Up data –

1. Anthropometric measurements at 18-22months corrected age
2. Neuro-developmental follow up at 18-22 months corrected age

Primary Outcome:

Growth in-hospital and at 18-22 months corrected age and in-hospital growth trajectories in high and low saturation arms.

Sample Size:

Given the importance of using an RCT to establish the impact of different levels of oxygen saturation from birth on short and long term growth, and recognizing the wealth of oxygen saturation data that will be available for analysis combined with the absence of comparable data in the literature, all infants in the SUPPORT Trial should be recruited into this secondary (n=1320). This sample size will be adequate to detect subtle differences in growth between the two groups with adequate ($\geq$80%) power. For example, this sample size will have at least 80% power to detect a difference in means between the two saturation groups of less than 40 g (assuming a mean weight of 1000 g in the control group and a standard deviation of 250 g) using a two group t-test with a 0.05 two-sided significance level.

Statistical Analysis:

Based upon intent-to-treat, differences between treatment arms with respect to continuous outcomes (such as weight, length, etc.) will be assessed by the Student t-test or the Mann-Whitney U-test, depending upon whether the empirical distribution of the data is approximately normal or heavily skewed. Adjusted analyses will be conducted using linear regression to determine the relationship between measures of oxygen saturation and growth in the presence of covariates and confounders (such as site, gestational age, gender, etc.). Categorical outcomes (such as BPD, growth failure, etc.) will be compared across treatment groups using the chi-square test. Logistic regression models will be developed to determine whether oxygen saturation independently affects growth after correction for confounding variables that also alter growth.

In-hospital growth data will be available over multiple points in time. Outcomes available from this temporal distribution will enable us to perform a longitudinal analysis comparing the trajectories of growth between the two treatment groups. Longitudinal studies are powerful both in terms of explanatory power and statistical efficiency. They are useful in examining whether children in the two different oxygen saturation arms have different developmental trajectories over time. Further, longitudinal studies are statistically more efficient since they acknowledge and account for naturally occurring differences among children, including unmeasured characteristics such as genetic make-up, prenatal exposures, etc.

In order to analyze longitudinal growth data we propose to use hierarchical modeling, where the first stage models growth as a function of time/child's age, and the second stage models this association as a function of each child's

treatment status. This flexible modeling formulation allows each child to have its own unique developmental trajectory, which could depend on its treatment status.

Discussion of Anticipated Results

We anticipate a better growth outcome in-hospital and at 18-22 months corrected age in the infants randomized to the lower target saturation range who maintained their median oxygen saturations within study range. We further anticipate that longitudinal analyses will demonstrate that these infants will have a sustained higher trajectory of growth over time compared to infants in the higher target saturation range.

Budget:

Additional nursing time, needed to collect required anthropometric data and other data from chart review at discharge and at follow-up, is estimated to be 1 hour. The cost for the entire cohort (1320 subjects), at $32.00 per nursing hour, would be $42,220. Assuming a 35% mortality for this extremely preterm population (estimated from GDB), 858 subjects could be expected to survive to discharge and estimating time for survivors alone will reduce the budget to $27,456.00.

Rose,
Can I provide the protocol for SUPPORT to an parent or grandparent? I know some of the
info is posted on trials.gov., but the full protocol is not so I wanted to make sure of the regs. Neil is in-flight, which is why I am asking you.

Wade

Post-natal Growth of Infants Enrolled in the NICHD Neonatal Network Oxygen Saturation (SUPPORT) Study: A Proposed Secondary Study

Cristina Navarrete MD, and Shahnaz Duara MD
University of Miami Miller School of Medicine, Miami, FL.

Abstract:

Post-natal growth restriction is a major problem in preterm infants. Perturbations in oxygenation are recognized to influence post-natal growth; hypoxic conditions can directly impair growth and hyperoxic conditions predispose infants to BPD, which in turn has been linked to poor growth. The NICHD Neonatal Network is conducting a prospective trial of preterm infants randomized to two levels of baseline oxygen saturations. The effect of baseline saturations on pulmonary morbidity and ROP are the primary outcome measures. With respect to post-natal growth, there is a paucity of data relating alterations in baseline oxygen saturation and/or frequent deviations above or below the baseline to growth outcomes. We propose a secondary study to quantify short-term growth velocity in-hospital and long-term growth at 18-22 months of corrected age for infants enrolled in the SUPPORT Trial in relationship to oxygen saturation.

A. Hypothesis to be tested

Primary:

1. Infants in the low oxygen saturation group (85-89%) will have better in-hospital and long-term (18-22 months corrected age) growth.

2. Trajectories of growth in hospital will be better for infants in the low oxygen saturation group.

Secondary:

1. Growth will be greater in infants who spend > 50% of the time with daily median oxygen saturation between 85% -95% while on supplemental oxygen, independent of randomization to low or high oxygen saturation.

2. Infants with BPD will have poorer in-hospital and long-term growth than infants without BPD, independent of the saturation randomization arm.

3. Better long-term growth will be positively related to neuro-developmental outcome, independent of the saturation randomization arm.

B. Specific Aims:

1. To determine anthropometric measurements (wt, HC, length) in infants randomized to low and high oxygen saturation arms, from birth to hospital discharge and again at 18-22 months corrected age.
2. To determine nutritional intake (parenteral and enteral) during hospital stay.
3. To determine the percentage of infants with growth <10 percentile at 36 weeks PMA or discharge, whichever comes first.
4. To determine the percentage of infants with growth <10 percentile at 18-22 months corrected age.
5. To determine growth in relation to the proportion of time spent with oxygen saturation
    a. <85% and >95%
    b. 85%-95%
6. To determine growth in relation to infants' median oxygen saturation while in supplemental oxygen
    a. median oxygen saturation > 95%
    b. median oxygen saturation 85% - 95%
    c. median oxygen saturation < 85%
7. To relate incidence of BPD in low and high saturation arms to growth.
8. To determine in-hospital growth velocity/trajectory in low and high saturation arms.
9. To determine long-term growth velocity/trajectory, from hospital discharge to follow up at 18-22 months corrected age in low and high saturation arms.
10. To relate neuro-developmental outcome at 18-22 months corrected age to long-term growth in low and high saturation arms.

Rationale:

The SUPPORT Trial will randomize infants to two ranges of SpO2 in order to test the hypothesis that use of a lower SpO2 range will result in an increase in survival of preterm infants without the occurrence of threshold retinopathy of prematurity and/or the need for surgical intervention. Retrospective cohort data from several units in the U.K., with different oxygen supplementation policies, revealed poorer growth patterns in the preterm infants exposed to higher oxygen saturations for the duration of oxygen exposure (Tin 2001). Conversely, observational data of infants with established BPD show better growth with home oxygen support (Groothius 1987), and two recent RCT of different target saturations in older oxygen-dependent premature infants showed no difference in short or long-term growth outcomes (STOP-ROP 2000, BOOST Trial 2003). There are no RCT data evaluating the short or long-term growth impact of different SpO2 strategies with supplemental oxygen use in a birth cohort of extremely preterm infants. Therefore, this study provides an opportunity for us to

obtain critically needed growth information on premature infants who are exposed from birth to different target oxygen saturation strategies.

Background

Improvements in antenatal care, respiratory support and nutrition have contributed to increased survival of ELBW infants. As the number of survivors increase, the long term outcome of these infants becomes more important. Lemons et al described growth failure or weight <10th percentile at 36 weeks postmenstrual age in 97% of ELBW infants surviving to discharge. Some morbidities in adulthood are linked to growth during the early post-natal period (Singhal 2004) and make adequacy of growth in this population of heightened interest.

Instead of following intra-uterine growth curves of age matched fetuses, VLBW infants exhibit wide-spread post-natal growth retardation (Cooke 2004), losing ground during the first weeks of life (Berry 1997). To resume growth post-natally, nutrition is of paramount importance; however, other factors such as severity of illness and perhaps oxygenation also play a role. Observational studies of infants with BPD showed poor post-natal growth when infants were sent home without oxygen supplementation (Markestad 1981).

Although preterm infants without lung disease attain oxygen saturations >95%, artificial attempts to keep arterial oxygenation at a "physiological" level may not be beneficial to growth, the lung or retina (Tin 2001). Animal studies have shown that newborn mammals (mice, rats, guinea pigs) develop poor growth with chronic hypoxia and that blunted body growth is directly proportional to the profundity of the exposure to chronic hypoxia (Mortola 1990). Chronic hypoxemia has also been suggested as the cause of poor growth in patients with cyanotic congenital heart disease (Dundar 2000). When home oxygen supplementation was discontinued inappropriately by parents in a cohort of VLBW infants with BPD, there was a deceleration in the rate of weight gain, which improved when oxygen supplementation was resumed (Groothius 1987). Hudak et al in 1989 observed that ELBW infants with CLD who went home on oxygen supplementation had good catch-up growth at 19 months. Taken collectively, these data suggest that hypoxic conditions affect growth negatively and supplementing oxygen may improve growth.

The optimal level of oxygen saturation to promote post-natal growth is unknown. Most of the available human data is limited to oxygen supplementation of infants who are oxygen dependent or have BPD. Baraldi et al demonstrated that discharged infants with BPD, who were kept on supplemental oxygen to keep saturations above 94%, had progressive but poor weight gain (stayed below 3rd percentile) at 9 months corrected age follow-up. In infants with BPD whose oxygen supplementation was intentionally discontinued, the subset who exhibited episodes of desaturations below 88-91% had a significant decline in the rate of weight gain as compared to those who maintained saturations above 92% (Moyer-Mileur 1996). Conversely, when two different oxygen saturation control policies (high: 88-98% and low: 70-90%) were retrospectively reviewed in <28

week gestation infants, the infants being cared for in the high oxygen saturation policy units were more likely to weigh less than the 3rd percentile at discharge (45% vs. 17%, Tin 2001). The infants assigned to the high oxygen saturation limits were also more likely to have BPD and ROP.

Recently, the BOOST Trial demonstrated that randomizing infants born <30 weeks gestation who were still on oxygen at 32 weeks postmenstrual age either to standard saturations (91-94%) or to high saturations (95-98%) produced no significant difference in growth at 12 months corrected age. This study, while randomizing infants to two different levels of saturations (conventional and high), only enrolled infants if they were still on oxygen supplementation at 32 weeks PMA and used higher limits than planned by SUPPORT. Our proposal is novel in that randomization to the two oxygen strategies begins at birth and continues for as long as the infants are in supplemental oxygen - by implementing this secondary we will be able to determine the impact of these strategies on short and long-term growth.

Methods:

Anthropometric Measures – at birth, postnatal days 7, 14, 21, and 28 days, 32 w PMA and 36 w PMA or discharge (wt, length, HC)

1. Weight - using standard digital electronic scales (c/o infant's nurse)
2. Length - using the Premie Length Board (average of two values, c/o research staff)
3. Head circumference - using paper measurement tape (average of c/o research staff)

Clinical Data-

1. Date when infant regains birth weight
2. Date of first enteral feed
3. Date of full enteral feeds (enteral > 120ml/kg/d)
4. Total number of days on parenteral nutrition
5. 24 h intake 'snapshots' (Parenteral, Enteral) – postnatal days 7, 14, 21, and 28, 32w PMA, 36w PMA or discharge (whichever comes first)
6. Presence of BPD

Intervention Data –

1. Duration of time spent in target saturation ranges of interest (Already part of SUPPORT‡)
2. Median values for unmasked oxygen saturation while still on supplemental oxygen therapy‡
3. Highest daily FiO_2‡
4. Duration of supplemental oxygen exposure‡
5. Documentation of post-discharge oxygen use

Follow Up data –

1. Anthropometric measurements at 18-22months corrected age
2. Neuro-developmental follow up at 18-22 months corrected age

Primary Outcome:

Growth in-hospital and at 18-22 months corrected age and in-hospital growth trajectories in high and low saturation arms.

Sample Size:

Given the importance of using an RCT to establish the impact of different levels of oxygen saturation from birth on short and long term growth, and recognizing the wealth of oxygen saturation data that will be available for analysis combined with the absence of comparable data in the literature, all infants in the SUPPORT Trial should be recruited into this secondary (n=1320). This sample size will be adequate to detect subtle differences in growth between the two groups with adequate ($\geq$80%) power. For example, this sample size will have at least 80% power to detect a difference in means between the two saturation groups of less than 40 g (assuming a mean weight of 1000 g in the control group and a standard deviation of 250 g) using a two group t-test with a 0.05 two-sided significance level.

Statistical Analysis:

Based upon intent-to-treat, differences between treatment arms with respect to continuous outcomes (such as weight, length, etc.) will be assessed by the Student t-test or the Mann-Whitney U-test, depending upon whether the empirical distribution of the data is approximately normal or heavily skewed. Adjusted analyses will be conducted using linear regression to determine the relationship between measures of oxygen saturation and growth in the presence of covariates and confounders (such as site, gestational age, gender, etc.). Categorical outcomes (such as BPD, growth failure, etc.) will be compared across treatment groups using the chi-square test. Logistic regression models will be developed to determine whether oxygen saturation independently affects growth after correction for confounding variables that also alter growth.

In-hospital growth data will be available over multiple points in time. Outcomes available from this temporal distribution will enable us to perform a longitudinal analysis comparing the trajectories of growth between the two treatment groups. Longitudinal studies are powerful both in terms of explanatory power and statistical efficiency. They are useful in examining whether children in the two different oxygen saturation arms have different developmental trajectories over time. Further, longitudinal studies are statistically more efficient since they acknowledge and account for naturally occurring differences among children, including unmeasured characteristics such as genetic make-up, prenatal exposures, etc.

In order to analyze longitudinal growth data we propose to use hierarchical modeling, where the first stage models growth as a function of time/child's age, and the second stage models this association as a function of each child's

treatment status. This flexible modeling formulation allows each child to have its own unique developmental trajectory, which could depend on its treatment status.

Discussion of Anticipated Results

We anticipate a better growth outcome in-hospital and at 18-22 months corrected age in the infants randomized to the lower target saturation range who maintained their median oxygen saturations within study range. We further anticipate that longitudinal analyses will demonstrate that these infants will have a sustained higher trajectory of growth over time compared to infants in the higher target saturation range.

Budget:

Additional nursing time, needed to collect required anthropometric data and other data from chart review at discharge and at follow-up, is estimated to be 1 hour. The cost for the entire cohort (1320 subjects), at $32.00 per nursing hour, would be $42,220. Assuming a 35% mortality for this extremely preterm population (estimated from GDB), 858 subjects could be expected to survive to discharge and estimating time for survivors alone will reduce the budget to $27,456.00.

Subject:	Re: Please Review: SUPPORT Follow-up MOO and Forms
Date:	Monday, October 17, 2005 6:29:11 PM

My comments on the manual and forms are as follows:

1-2 Section 1.5: NICU Discharge: Though this is covered in more detail on 7-1, would suggest inserting after "prior to NICU discharge" the following: "or within 30 days post discharge"

For 6 and 12 month interviews, would suggest deleting "telephone" and then adding "by telephone or face-to-face" (as specified on 2-6 and 5-2).

2-5 Section 2.3.3 I don't have a problem encouraging families to use the diaries, but I think it unrealistic to expect the average family we deal with to keep it up over a period of 6 months with any degree of consistency/completeness. Granted whatever they do record may bolster 6 month recall, but I don't think we should only ask them to report what they have recorded, unless they are confident that it is complete.

3-1 Section 3.3 Though the amount of text added to the main SUPPORT consent form to include the follow-up study is modest, and the follow-up design is not complicated, the main trial is more involved, and I suspect it may be all some parents can do to understand and consent to the main trial, especially at the time sensitive point the main trial consent needs to be obtained. Not to mention the fact that a not insignificant percent of the smallest infants may not survive. Though it would be nice to get it all out of the way up front, I think someone will still need to rediscuss the follow-up study closer to discharge or shortly therafter.

5-2 Discharge The questionnaire in Appendix B actually comprises 25 questions, some of which are multi-part. The first 6 are demographic, 11 concern home environment, 2 relate to diet, 1 provides alternate contact info, and a separate 5 cover family history (also multipart). The description here should reflect that.

Likewise, the 6 and 12 month questionnaires comprise a total of 27 questions (again, some mult-part); and the 18-22 month form includes those 27 plus another 7 concerning 1 year history of infection/allergy.

5-3 Section 5.4 Might want to cross-reference 7-1 with regards to the definition of "windows" for each of the questionnaires.

7-2 Intro The second paragraph of the intro script indicates "it may be helpful if you could gather...." This suggests that some interviews may proceed without the requested items, if, for example diary cannot be found or has not been kept, or if meds are not readily available at the time of the call. Though it might be of some interest to ask/note whether and to what extent the answers are based on pure recall vs. diary (or medication containers), I'm not sure how one would meaningfully use that info to characterize/qualify results.

7-3 Question 6-8 Since the symptom of wheezing is included in these 3 utilization questions, the definition of

wheezing and audio clip really needs to be introduced prior to these questions; alternatively, 6-8 could be moved down to follow 9-15.

7-5 Q. 9e1-9f2 Do these questions literally refer to the last 6 months, or should they, like 6-8, be limited to the period since the last contact? Same for Q. 11-12.

7-7 Q. 11-12 Secondly, I think averaging over 6 months will be a challenge except in the case of the child with relatively infrequent, or conversely frequent, sx.

7-7 Q. 10c It is not clear what kind/duration of cough "the cough" refers to. Are we really interested in the first time the child had a 3-4 day URI associated cough?

Or are we more interested in the first month the child had a cough without cold, that persisted more than a few days?

7-7 Q. 12 Typo: "...change your (not for) daytime or evening plans...."

7-11 Q. 26 Might want to note that "pure oxygen is 100%"

8-1 Actually,questions 28-29 are not principally about allergies, but about upper or lower respiratory tract infections. Would suggest a separate intro for these 2 questions, since the allergy intro might mislead the parent in answering 28-29.

Appendix C C-2 The last paragraph under Procedures needs to be omitted, since we are dropping the chart audit.

C-6 the first sentence of the last paragraph adds language about "wheezing in the first 2 years" but does not mention "coughing"

Appendix E Breathing Diary Blank. See comments above re diary.

Appendix B 6, 12, 18-22 month questionnaires:

Questions 9e-f; 10e-f: There is a big difference between never and twice a week for daytime, but if that's the key threshold we are interested in, fine.

Question 13: As I mentioned at our last meeting, I think this question is going to miss those infants whose physicians continue to carry them under the NICU discharge diagnosis of BPD/CLD, in which case future events are considered "flare-ups" of that chronic disease, rather than just "reactive airway disease" or "asthma" variants, which should only be applied if there is evidence to support that alternate/additional diagnosis.

Thus I would still recommend including BPD/CLD or flare-ups thereof in question 13, assuming we don't need/want to separate it out as a separate question.

Question 27: Since all of the meds in the first column of the table can be inhaled, I would modify the label for Intal and Tilade "Other Inhaled Medications"

Prednisolone is not included in your list of systemic steroids.

Finally, has the protocol been modified to reflect certain key changes in questionnaire administration (such as possibility of face to face and windows for admin); and to reflect omission of the outpatient chart review, since it is the protocol and consents that we submit to IRB, rather than manual of ops. There is also one table in the protocol (Table 1 on page 8), which lists Important Covariates, which I don't think has been updated to reflect streamlining of the questionnaires, since the current questionnaires no longer ascertain info in the Environmental category regarding urban vs rural residence, presence of dust; nor either of the listed Health Services parameters, as far as I can tell; nor info re GERD or congenital anatomic airway abnormalities (unless these were diagnosed and captured in the NICU).

Dear Follow-up PIs and Coordinators,

Attached are the SUPPORT Follow-up Manual of Operations and questionnaires for your review and comments.

The agenda for the next Coordinators' call on Thurs 10/20 has already been set though we would very much like your comments.

It has been difficult finding a day/time that fits the PI's schedules so we are expanding the date/time options. Please let me know your availability for these additional times:

Thursday, October 20: afternoon

Friday, October 21: 12-3

Monday, October 31: 4-5pm

Tuesday, Nov 1: afternoon

Wednesday Nov 2: afternoon

Thurs Nov 3 afternoon

Friday Nov 4 afternoon

Thank you,

Jamie E. Newman, MPH

Rose
When we do get the Follow-up PI's on a call can I add 2 items to agenda
a) Revised Extended Follow -UP study of Hypothermia subjects (will send out the additions of NEPSY/deletions Beery, VMI)
b) Minor change in aEEG FU form (to ensure that the "untestable" children are coded correctly and not as "missing"
What do you think
Let me know
Thanks
Seetha

Subject: RE: Please Review: SUPPORT Follow-up MOO and Forms

I have a few comments for the conference call.

1. In the directions on page 1 I would change it to administered by trained study staff to the parent/guardian. At the moment it states a nurse and some of the IRBs might have a problem if a physician or other trained professional(respiratory therapist) administered the questionnaire.

2. The breathing diary was not forwarded. There was nothing in Appendix E. ?

3. The questionnaires need to have a place on each page to put the study number as an identifier.

4. The parent name is requested on the form. This conflicts with current confidentiality requirements. I believe that the code is adequate.

5. Family history form for maternal and paternal grandparents. How is this to be filled out if the person has expired,or if the person being interviewed does not have the information ?

6. Linda Mayes is not the Follow-up PI at Yale, it is Richard Ehrenkranz.

SUPPORT Trial
Pulmonary Outcomes Follow-up Study

The SUrfactant Positive Airway Pressure and Pulse Oximetry Trial in Extremely Low Birth Weight Infants (SUPPORT Trial)

NICHD Neonatal Research Network

Manual of Operations

October 12, 2005

TABLE OF CONTENTS

Chapter 1
Overview and Trial Design

1.1 Introduction

This manual provides detailed instructions of study procedures for the Follow-up Study of the NICHD SUPPORT Trial Pulmonary Outcomes Follow-up Study (The SUrfactant Positive Airway Pressure and Pulse Oximetry Trial in Extremely Low Birth Weight Infants). This manual should be used as a reference guide for study staff including investigators, coordinators, and data managers. The trial objectives and design are summarized briefly below. For further discussion to the study background and design, please refer to the Follow-up Study Protocol.

1.2 Study Design

This study is a longitudinal follow-up of surviving infants enrolled, randomized and treated as part of the SUPPORT Trial, which was a prospective, randomized, factorial 2X2 design multi-center trial conducted by the NICHD Neonatal Research Network. This follow-up study will determine the effect of lower targeted oxygen saturation ranges and more aggressive use of CPAP on the incidence of symptomatic airway dysfunction (defined as recurrent wheezing or chronic cough) and volume of outpatient care in the first 18-22 months' corrected age (CA). The individual factors to be tested in this follow-up study are:

1) Symptomatic airway dysfunction and need for outpatient pulmonary care in the first 18-22 months among infants managed with a lower SpO2 range (85% to 89%) as compared to a higher, more conventional SpO2 range (91% to 95%).

2) Symptomatic airway dysfunction and need for outpatient pulmonary care in the first 18-22 months corrected age among infants managed with CPAP and a permissive ventilatory strategy versus infants managed with prophylactic surfactant and conventional ventilation begun in the delivery room and continuing in the NICU.

Table 1 below describes the study treatment groups. Refer to the SUPPORT Trial Protocol for further details regarding the projected outcomes relative to the study interventions

Table 1: SUPPORT Trial Study Treatment Groups

Randomized Intervention	**Low SpO2 85% to 89%**	**High SpO2 91 to 95%**
Treatment Early CPAP	Early CPAP + Low SpO2	Early CPAP + High SpO2
Control Prophylactic/Early Surfactant	Control + Low SpO2	Control + High SpO2

1.3 Primary Hypotheses

1) We hypothesize that relative to infants managed with a higher SpO2 range (91% to 95%), infants managed with a lower SpO2 range (85% to 89%) will have less frequent episodes of

symptomatic airway dysfunction and reduced need for outpatient pulmonary care at 18-22 months' CA.

2) We hypothesize that relative to infants managed with prophylactic surfactant and conventional ventilation, infants managed with early CPAP and permissive ventilator strategy will have less frequent episodes of symptomatic airway dysfunction and reduced need for outpatient pulmonary care in the first 18-22 months' CA.

1.4 Secondary Hypotheses

1) We hypothesize that **among infants with CLD**, infants managed with a lower SpO2 range relative to those managed with a higher SpO2 target range and infants managed with early CPAP and permissive ventilator strategy compared with those managed with prophylactic surfactant and conventional ventilation will have less frequent episodes of symptomatic airway dysfunction and reduced need for outpatient pulmonary care during the first 18-22 months' CA.

2) We hypothesize that **among infants without CLD**, infants managed with a lower SpO2 range relative to those managed with a higher SpO2 target range and infants managed with early CPAP and permissive ventilator strategy compared with those managed with prophylactic surfactant and conventional ventilation will have less frequent episodes of symptomatic airway dysfunction and reduced need for outpatient pulmonary care during the first 18-22 months' CA.

1.5 Summary of Data Forms

The following is a summary of the data forms used in this study. Further details on each form are provided in subsequent chapters. A complete set of forms can be found in Appendix A.

NICU Discharge-Baseline Interview (SUPF01)
This interview will be administered to the parent or guardian by a trained study nurse prior to NICU discharge. Questions concerning family medical history, anticipated living arrangements, and alternate contact information will be asked.

The purpose of the discharge questionnaire is to assure adequate randomization of important covariates affecting outpatient respiratory health and to obtain baseline data on home environment and family history of respiratory diseases.

6 Month and 12 Month Interview (SUPF02)
This interview will be administered to the parent or guardian by a trained telephone interviewer at 6 months' CA and again at 12 months' CA.

The purpose of these questionnaires is to obtain an **interval** respiratory history. Questions are designed to collect respiratory history since the last contact with the interviewee, such that when the 6, 12 and 18-22 month questionnaires are taken together, a complete respiratory history over the time period is collected.

18-22 Month Interview (SUPF03)

This interview will be administered to the parent or guardian at 18-22 months CA by either telephone interview prior to the regularly scheduled 18-22 month NICHD developmental follow up clinic visit or face to face at the time of the visit.

The purpose of these questionnaires is to obtain an **interval** respiratory history and to identify environmental exposures that may increase the likelihood of symptomatic airway dysfunction.

Chapter 2
Administration

2.1 Organizational Structure

The NICHD Neonatal Research Network is conducting this study. The Network is funded by the NICHD under cooperative agreements with seventeen institutions comprised of sixteen clinical centers and a data coordinating center. The Steering Committee for the Network consists of the Principal Investigator from each clinical center, the data center, and the NICHD project officer. The Steering Committee Chairman is appointed by NICHD and is not a Principal Investigator from any of the Clinical Centers.

SUPPORT Trial Follow-up Subcommittee

The SUPPORT Protocol Subcommittee is responsible for the preparation and maintenance of the protocol, data forms, and manual of operations. This subcommittee will monitor the overall study performance (including protocol compliance) and will report the progress of the trial to the Steering Committee. SUPPORT Subcommittee members are:

Neil Finer, MD

Waldemar A. Carlo, MD,

Edward F. Donovan MD

Michele Walsh, MD

Shahnaz Duara, MD

Rosemary D. Higgins, MD

Abhik Das, PhD

Ruth Everett, RN

Wade Rich, RRT

In addition, Dr. Vohr, as director of the Follow Up Program, will coordinate input from the Follow Up PIs. Timothy P. Stevens, MD, MPH and Peter Szilagyi, MD, MPH from the Department of Pediatrics at the University of Rochester will be instrumental in designing, implementing and executing the clinical studies outlined here and will have significant ongoing involvement with the project.

2.2 Participating NICHD Neonatal Research Network Centers

Centers from the NICHD Neonatal Research Network participating in the trial are listed below. The NICHD center number is indicated in parentheses next to the name of each center. The Neonatal Research Network principal investigators (PIs) are located in the second column, the Follow-up PIs in the third column and the SUPPORT Study PIs in the fourth column.

PARTICIPATING CENTERS	NRN PI	NRN Follow Up PI	SUPPORT STUDY PI
Case Western Reserve Univ. (3) Rainbow Babies and Children's Hospital	Michele Walsh, MD	Dee Wilson, MD	Michele Walsh, MD
University of Texas-Dallas (4)	Charles Rosenfeld, MD	Roy Heyne, MD	Walid Salhab, MD
Wayne State University (5) Children's Hospital of Michigan	Seetha Shankaran, MD	Yvette Johnson, MD	Seetha Shankaran, MD
University of Miami (8) Jackson Memorial Hospital	Shahnaz Duara, MD	Charles Bauer, MD	Shahnaz Duara, MD
Emory University (9) Grady Memorial Hospital	Barbara J. Stoll, MD	Ira Adams-Chapman, MD	Susie Buchter, MD
University of Cincinnati (11) University of Cincinnati Hospital	Edward F. Donovan, MD	Jean Steichen, MD	Vivek Narendran, MD Kurt Schibler, MD
Indiana University (12)	James A. Lemons, MD	Anna M. Dusick, MD	Brenda Poindexter, MD
Yale University (13) The Children's Hospital at Yale – New Haven	Richard A. Ehrenkranz, MD	Linda Mayes, MD	Vineet Bhandari, MD
Brown University (14) Women and Infant's Hospital	William Oh, MD	Betty R. Vohr, MD	Abbot Laptook, MD
Stanford University (15) Stanford University Med Center	David K. Stevenson, MD	Susan R. Hintz, MD	Krisa Van Meurs, MD
University of Alabama (16) University of Alabama at Birmingham	Waldemar A. Carlo, MD	Myriam Peralta, MD	Waldemar A. Carlo, MD
University of Texas- Houston (18)	Jon E. Tyson, MD	Jon Tyson, MD	Brenda Morris, MD
Duke University (19)	Ronald Goldberg, MD	Ricki Goldstein, MD	C. Michael Cotten, MD
Wake Forest University (20)	Michael O'Shea, MD	Robert Dillard, MD	Michael O'Shea, MD
Golisano Children's Hospital at Strong (21) University of Rochester	Dale L. Phelps, MD	Gary Myers, MD	Nirupama Laroia, MD
University of California-San Diego (22)	Neil Finer, MD	Yvonne Vaucher, MD	Neil Finer, MD

2.3 Responsibilities of Clinical Centers

The minimum staff required for network participation at each clinical center is the physician Principal Investigator (PI), the Research Coordinator, and telephone interviewers, if interviews are not conducted by the Research Coordinator.

The research coordinator may identify another individual to conduct the telephone interviews. In this situation, it will be the coordinator's responsibility to assure that the interviewer is certified in standardized administration of the questionnaire (see below). The responsibilities of these individuals are described briefly in this chapter and in more detail in subsequent chapters.

The PI or designee is responsible for ensuring the proper conduct of the trial at his or her clinical center (including recruitment and treatment of patients as specified in the protocol), accurate collection of data and transmission of information to the Data Coordinating Center (DCC). Other specific duties include the following:

- Presenting an in-service to the other physicians
- Applying for IRB approval
- Introducing the study to the parents of prospective patients, and obtaining signed informed consent from the parents of eligible infants (in some centers this responsibility may be delegated)
- Reviewing all infants for whom informed consent has been obtained to confirm their eligibility
- Informing the IRB of the study progress.

The Research Coordinator will be responsible for the day-to-day operations of the study at the clinical center, including data collection and management. This responsibility includes the following:

- Collecting information necessary to complete the data collection forms, and coordinating data entry
- Training and certifying the staff in the use of the network computer
- Controlling access to the network computer and ensuring that required back-up, security and confidentiality are maintained
- Responding to edit messages and other communications from the data center
- Distributing updates of the protocol and of the manual of operations to clinical center staff
- Further responsibilities are based on the study administration option chosen by the center.

2.3.1 Delineation of Responsibilities by Study Administration Option

Clinical Centers have the option of administering the follow-up questionnaires to their own patients (Option 1) or having telephone interviewers of the University of Rochester Health Services Research Group administer the follow-up questionnaires to their patients (Option 2). Table 2 indicates which option the centers have chosen.

Table 2. **SUPPORT Trial - Pulmonary Outcomes Study**

NICHD Site	*6, 12 and 18-22 Month Pulmonary Questionnaires Administered By*	Option Number
Alabama	Alabama	1
Brown	Brown	1
Cincinnati	Cincinnati	1
CWRU	CWRU	1
Dallas	Dallas	1
Duke	Duke	1
Emory	Rochester	2
Houston	Rochester	2
Indiana	Rochester	2
Miami	Miami	1
Rochester	Rochester	2
Stanford	Rochester	2
UCSD	UCSD	1
Wake Forest	Wake Forest	1
Wayne State	Wayne State	1
Yale	Yale	1

Regardless of the option chosen, each local center is responsible for obtaining informed consent, administering the NICU Discharge-Baseline Interview (SUPF01) and distributing the respiratory diary to parents, as well as tracking patients following discharge. Table 3 further describes the responsibilities of the local center and Rochester in Option 1 and Option 2.

Table 3.	Option 1	Option 2	
	Local Center	Local Center	Rochester
Consent / IRB	✓	✓	
Questionnaire at Discharge	✓	✓	
Patient Tracking	✓	✓	
Questionnaire at 6 & 12 mo.	✓		✓
Questionnaire at 18-22 mo.	✓		✓
Data Entry (questionnaires)	✓		✓

Each of the responsibilities discussed in table 3 above will be discussed separately below.

2.3.2 Consent

For both options, every effort will be taken to enroll ALL SUPPORT patients into the Pulmonary Outcomes Study, including both currently enrolled SUPPORT patients (both patients still in NICU and those discharged from the NICU) and all future enrollees. By obtaining pulmonary outcome data for both current and future SUPPORT patients, death or adverse pulmonary outcome can be analyzed as competing outcomes. Sample consent forms for currently enrolled and future SUPPORT patients are attached.

2.3.3 Discharge Questionnaire

The purpose of the discharge questionnaire is to assure adequate randomization of important covariates affecting outpatient respiratory health and to obtain baseline data on home environment and family history of respiratory diseases. There are a total of 16 questions on the questionnaire; 9 questions on home environment and exposures, 1 question on alternate contact information, 6 questions on family history of allergy and respiratory problems.

Each center, regardless of study option chosen, will administer the discharge questionnaire. This will allow ascertainment of baseline data as well as confirming contact information for the family. For patients enrolled into the Pulmonary Outcomes Follow up Study after NICU discharge, this questionnaire can be administered prior to the 6 month questionnaire.

After completing the discharge questionnaire, parents should be given the respiratory diary and instructed to record how often their baby has wheezing or coughing, whether the baby visited a doctor's office, emergency room or was hospitalized for breathing problems. Parents should be asked to gather the diary and any medications or other information about their baby's breathing when the interviewer calls in six months.

2.3.4 Tracking

All centers (Option 1 and 2 centers) will track their own patient's telephone and contact information for the purpose of administering telephone questionnaires at 6, 12 and 18-22 months. This will also help assure attendance at the routine NICHD neurodevelopmental follow up clinic visit 18-22 months.

The following core set of contact information is recommended for all enrolled patients.

- Network number
- Patient Name
- DOB
- Gender
- Name of Prior Interview Respondent (if different than primary care taker)
    - Primary Caretaker Contact Information
        - Name
        - Relationship to patient
        - Mailing address
        - Telephone number #1
        - Telephone number #2
    - Secondary (Backup) Caretaker Information
        - Name
        - Relationship to patient
        - Mailing address
        - Telephone number #1
        - Telephone number #2

2.3.5 Responsibility of Option 1 Centers In Administering Questionnaires at 6, 12 And 18 Months' Corrected Age

Clinical Centers will have the option of administering the follow-up questionnaires to their own patients (Option 1) or having telephone interviewers from the University of Rochester Health Services Research Group administer the follow-up questionnaires to their patients (Option 2).

- Standardization of Interview Technique
  - In order to assure that interviews are administered in a standard and consistent manner, the University of Rochester Health Services Research Group will conduct an Interviewer Certification Program to train interviewers at Option 1 centers and Rochester based interviewers. All interviews must be performed by certified interviewers (see 2.4.7 below).

- Conducting the Interviews
  - Prior to each interview, a postcard will be mailed to the family reminding them to expect a telephone call.
  - For centers that see patients in an office setting, the questionnaire may be administered face to face.

2.3.6 Responsibility of Option 2 Centers In Administering Questionnaires at 6, 12 And 18 Months' Corrected Age

- Upon receipt of RTI reminder, Option 2 Centers will send a postcard to the family reminding them to expect a telephone call.
- Review and update contact information as necessary and fax contact information to the Rochester Health Services Research Group (RHSRG).
- The RHSRG will conduct the telephone interview.
- At the conclusion of each interview, contact information will be confirmed and updated contact information faxed back to the Option 2 Center.

2.3.7 Responsibilities of the University of Rochester Health Services Research Group

- The certification program will consist of two parts.
  - Part 1 - a teleconference training session during which each question on the questionnaires is reviewed and discussed with the interviewers. The goal is to assure that interviewers understand the purpose of each question and, in a standard way, how to deliver the question, elicit an answer and record the interviewee's response.

  - Part 2 will consist of a practice interview in which interviewers from each center interview the Rochester trainer, who simulates a standardized patient. Following the practice interview, the Rochester trainer and practice interviewer will discuss the interview and give feedback.

- Other responsibilities include:

- Development and distribution of an audio clip of wheezing to be presented along with a verbal definition to the interview respondent to standardize interpretation of wheezing and to minimize ascertainment biases due to language, culture, literacy or interviewing techniques.

- Maintaining trained Spanish-speaking individuals to conduct the telephone interviews with Spanish-speaking participants from centers choosing Rochester to administer the questionnaire to their patients (Option 2).

- Spanish language versions of the questionnaires will be created and made available to all centers. The Cornell Translation Service, a University based professional translation service, will be contracted by the University of Rochester to perform the translation.

2.4 Responsibilities of the Data Coordinating Center

The DCC at RTI International is responsible for all aspects of statistical design and analysis as well as data management of the study. In particular, this includes:

- Processing, updating and distributing the protocol and manual of operations
- Developing and distributing the data forms, including periodic updates as necessary
- Developing, testing and implementing the database and other software. Ensuring that data are correct and complete by implementing editing and auditing procedures
- Monitoring the progress and quality of the study
- Preparing interim and final analyses and reports
- Participating in the preparation of presentations and publications relating to the study

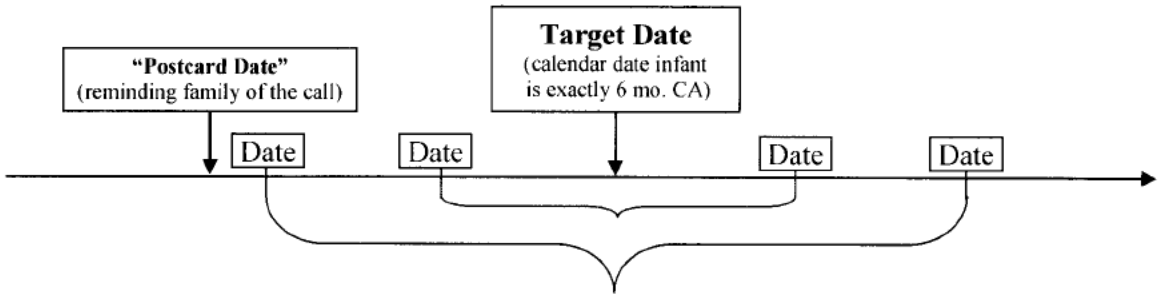
The DCC is also responsible for sending monthly reminder reports to Network Centers. For patients enrolled in the Pulmonary Outcomes Study, the DCC will send a monthly reminder to each center with a list of IDs that are due to have questionnaires conducted. The report will include the following:

- Network number
- Gestational age
- Gender
- Date of last interview
- Care taker (relationship code) providing the previous interview
- Whether the previous interviews were conducted face to face or by telephone
- List of the 4 interviews that have been completed (CA = corrected age)
- Completed interview dates, dates of previous interviews and interviewee information may be presented as outlined in the table below.

Example table

Required Interviews	Date	Caretaker Interviewed	Face to Face?
▪ Discharge	__/__/__	_____	Y or N
▪ 6 month CA	__/__/__	_____	Y or N
▪ 12 month CA	__/__/__	_____	Y or N
▪ 18-22 month CA	__/__/__	_____	Y or N

- Target date for the current interview with windows within which interview should be accomplished, goal window (target date ± 2 weeks) and acceptable window (target date ± 4 weeks)
- A "postcard date", 5 weeks prior to the contact, when a postcard might be sent to the family reminding them of the upcoming call or visit



2.5 Responsibilities of NICHD

In addition to its role as a funding agency, the NICHD participates in the activities of the cooperative agreement by being represented on the Steering Committee. The Program Official also participates in the development of protocol and in assisting the Steering Committee in the coordination of the studies conducted by the Network. The NICHD Program Official, in conjunction with the RTI Principal Investigator is responsible for monitoring site performance of all participating centers. The Program Official has the following responsibilities:

- Assistance in the development of the study protocol.
- Assistance in the development of capitation-based budgets, including the identification of study costs and special institutional needs.
- Allocation of network resources to meet study needs.
- Facilitation of training meetings, site visits, and subcommittee meetings.
- Participating in preparation of publications.

Chapter 3
Screening, Eligibility, Consent

3.1 Study Population

This follow-up study will include all surviving infants enrolled, randomized and treated as part of the multi-center NICHD Neonatal Research Network SUPPORT Trial, which were inborn infants of 24 0/7ths to 27 6/7th weeks at birth for which a decision was made to provide full resuscitation as required. Infants 27 weeks or less gestation (completed weeks by best obstetric estimate) were enrolled.

Inclusion Criteria

- Enrollment in the SUPPORT Trial
- Survival to hospital discharge
- Consent for enrollment into the Pulmonary Outcomes Follow up Study, obtained either at the time of enrollment into the SUPPORT Trial or separately.

3.2 Exclusion Criteria

- Refusal of informed consent

3.3 Informed Consent

Every effort will be taken to enroll ALL SUPPORT Trial patients into the Follow-up Study, including currently enrolled SUPPORT patients (both patients still in NICU and those discharged) and future enrollees. By obtaining pulmonary outcome data for both current and future SUPPORT patients, death or adverse pulmonary outcome can be analyzed as competing outcomes. Each local center will be responsible for obtaining informed consent for the Follow-up Study regardless of whether they are administering the follow-up questionnaires to their patients or Rochester is conducting the telephone interviews.

For future enrollees in the SUPPORT Trial, consent for the Follow-up study will be obtained at the time of enrollment in the main trial. As described in the SUPPORT Trial Manual of Operations, these infants will be recruited for the study by approaching one or both parents at the time of admission to the hospital at risk for premature delivery at 27 weeks or less. It is anticipated that, whenever possible, the parents will be approached by study personnel to discuss the trial and obtain an informed consent for the participation of the infant at delivery. Randomization will be by family, thus all offspring will be randomized to the same trial arms, provided adequate equipment and personnel are available at the time of delivery. Sample consent forms for currently enrolled and future SUPPORT patients are attached (Appendix C).

3.4 Screening Procedures

This follow-up study will include all surviving infants enrolled, randomized and treated as part of the NICHD Neonatal Research Network SUPPORT Trial.

For future enrollees in the SUPPORT Trial, all admissions for threatened premature delivery will be screened on a daily basis to ensure that eligible patients can be enrolled. Obstetrical colleagues at each participating institution will be informed of the nature of this study and encouraged to discuss this study with their patients at risk of premature delivery. The study coordinator at each site will maintain a screening log of potentially eligible patients. In addition, the usual practice of neonatal consultation for all such at risk deliveries will provide a second opportunity to approach mothers with fetuses at risk of preterm delivery.

Chapter 4
Randomization

4.1 Randomization Procedures

Randomization for the NICHD Neonatal Research Network SUPPORT Trial was stratified by gestational age group (24 - 25 6/7 and 26 - 27 6/7) and occurred prior to delivery for consented deliveries. The randomizations were performed by utilizing specially prepared envelopes. The Data Center prepared brown sealed envelopes which contained the identity of the treatment combination that were assigned to the infants enrolled into the study. Deliveries were randomized as a unit, thus multiples, twins, triplets etc were randomized to the same arm of the trial. One envelope corresponded to the delivery of a consenting mother regardless of the number of babies delivered so that all babies from a given delivery received the same treatment combination.

Refer to Section 4.1.1 of the NICHD Neonatal Research Network SUPPORT Trial Manual of Operations (MOO) for more information on randomization and masking as well as storing and assigning oximeters that occurred during the main study.

During the Follow-up Study activities, research coordinators and telephone interviewers, if different from the research coordinators, will remain blinded as to whether infants were randomized to the control or treatment group.

Chapter 5
Follow-up Study Procedures

5.1 SUPPORT Trial Study Interventions

Refer to Chapter 5 of SUPPORT Trial Manual of Operations (MOO) for more information on the study interventions and the procedures for the treatment groups. The same questionnaires will be administered to both treatment groups in the Follow-up Study.

5.2 Pulmonary Follow Up Study Interventions

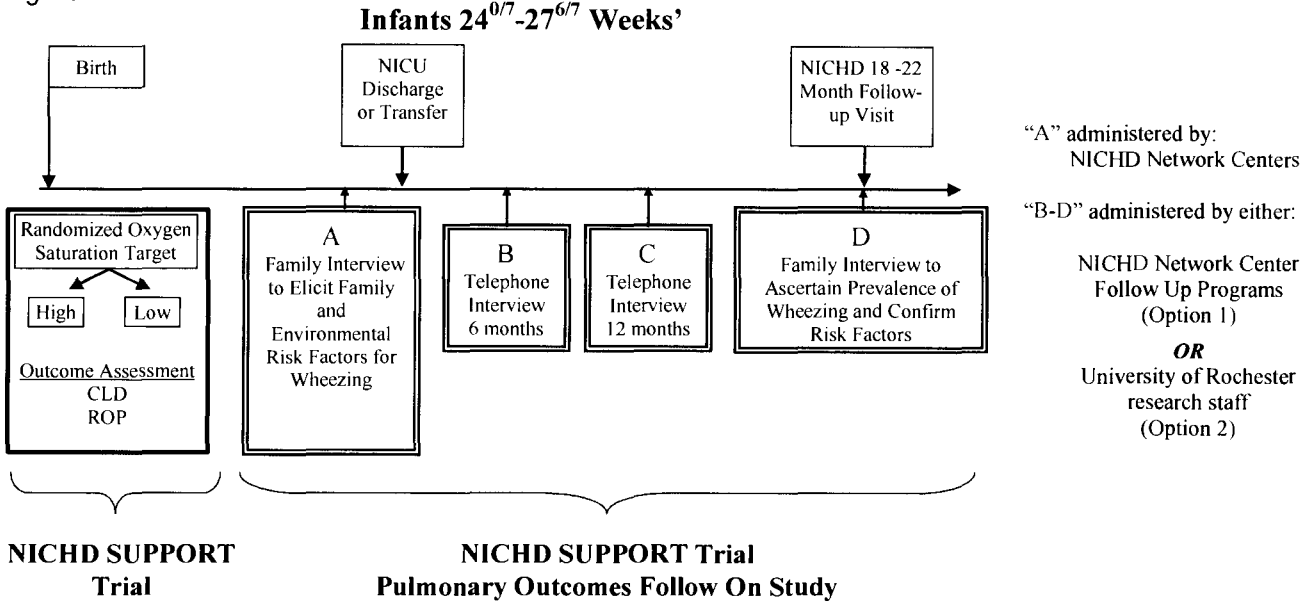
Before delivery, infants will be randomized according to the 2x2 factorial design of the SUPPORT Protocol.

The SUPPORT Follow-up Study of Pulmonary Outcomes begins just prior to NICU discharge. See Figure 1 for a diagram of the SUPPORT Trial Follow-up Study procedures.

Four questionnaires will be administered at approximately 6 month intervals until the baby is 18-22 months' corrected age according the schedule outlined in Figure 1. Each interview will collect a 6 month interval history, which, when taken together, will provide a complete respiratory history over the first 18-22 months' corrected age. If a questionnaire is not completed, the subsequent questionnaire will include the full interval history since the last completed questionnaire.

SUPPORT Trial Follow-up Study

Figure 1.



DESCRITION OF QUESTIONNAIRES

A) Discharge Questionnaire Administered by Network Centers

The discharge interview consists of a primary caretaker (parent or guardian) interview to elicit family and environmental risk factors for wheezing and cough. The family interview will be administered at each participating Network Center by site study nurses prior to NICU discharge or transfer. The questions are based on intake questions used by the Tucson Respiratory Study and are designed to elicit family history of asthma, atopy, and home environmental exposures and to identify likely care givers.

The purpose of the discharge questionnaire is to assure adequate randomization of important covariates affecting outpatient respiratory health and to obtain baseline data on home environment and family history of respiratory diseases. There are a total of 16 questions on the questionnaire; 9 questions on home environment and exposures, 1 question on alternate contact information, 6 questions on family history of allergy and respiratory problems.

Each center, regardless of study option chosen, will administer the discharge questionnaire and perform data entry. This will allow ascertainment of baseline data as well as confirming contact information for the family.

B) Respiratory History Questionnaires Administered at 6 and 12 Months' Corrected Age

The purpose of this questionnaire is to obtain an **interval** respiratory history. Questions are designed to collect respiratory history in areas outlined in the table at right. For centers choosing Option 1, interviews may be conducted either by telephone or face to face. For centers choosing Option 2, interviews will be conducted long distance by telephone from The Rochester Health Services Research Group to the family.

Outcome	Question No.
Respiratory Symptoms	9, 10, 13-15
Quality of Life	11, 12
Health Services Utilization	
Office	6
Emergency Department	7
Hospitalization	8
Medication Use	27
Oxygen Use	26
Preventive Services	24, 25
Exposures	16-23

C) Respiratory and Environmental Exposure History Questionnaires Administered at 18-22 Months' Corrected Age

The purpose of this questionnaire is to obtain an **interval** respiratory history and to identify environmental exposures that may increase the likelihood of symptomatic airway dysfunction. Questions are designed to ascertain the frequency and severity of wheezing and cough episodes and to assess the need for outpatient pulmonary care. In addition, a history of atopy is elicited. There are a total of 30 questions, encompassing questions from the discharge and 6 and 12 month questionnaires.

This parent interview may also be administered either by telephone prior to the regularly scheduled 18-22 month NICHD developmental follow-up clinic visit or face to face at the

time of the visit. Contacting parents prior to the office visit will help improve the Developmental Follow Up Clinic attendance rate. Otherwise, the clinic visit will provide a back up means to contact the family. The 18-22 month interview will be conducted either by the local NICHD Follow Up Program (Option 1) or long distance from Rochester (Option 2), based on center preference (see table 2 below).

5.3 Administration of the Follow-up Questionnaires

- The questionnaires are for research only. Caretakers, parents or guardians expressing concern regarding the child's breathing should be encouraged to discuss their concern with the family's primary care physician. Diagnostic or treatment advice should NOT be offered as part of the interview.

5.4 Protocol Violations

The occurrence of any one of the following criteria will determine whether an individual infant will be considered a protocol violation:

- Interview occurring outside the window
- Missed interview

In both of these cases the interview should be conducted at the next available opportunity and should encompass respiratory health since the prior interview.

All protocol violations will be reviewed by the center PI who will discuss each protocol violation with the involved clinicians, identifying steps to avoid future violations.

5.5 Adverse Events

We anticipate no risk to the patient from this observational follow-up study.

Serious adverse events were anticipated in the main SUPPORT Trial for this vulnerable population. Refer to Section 5.5 of the NICHD Neonatal Research Network SUPPORT Trial MOO for more information on adverse event reporting and monitoring.

Chapter 6
NICU Discharge-Baseline Interview

Introduction

The purpose of the discharge questionnaire is to assure adequate randomization of important covariates affecting outpatient respiratory health and to obtain baseline data on home environment and family history of respiratory diseases. There are a total of 16 questions on the questionnaire; 9 questions on home environment and exposures, 1 question on alternate contact information, 6 questions on family history of allergy and respiratory problems.

Each center, regardless of study option chosen, will administer the discharge questionnaire and perform data entry. This will allow ascertainment of baseline data as well as confirming contact information for the family.

Instructions for Completing the NICU Discharge-Baseline Interview (SUPF01)

Timing of the Interview:

This interview should be administered to the parent/guardian by a trained study nurse prior to or within the first 30 days following NICU discharge. If for any reason the infant is enrolled into the Pulmonary Outcome Study later than 30 days following NICU discharge, the questionnaire should be administered prior to interval questionnaires (SUPF02 or SUPF03)

Heading- Infant's Identification
The following information is included in the heading section of all patient specific data forms: Center, Site, Network Number, SUPPORT Follow-up Number, Birth Number and Mother's Initials **(optional).** This information should be completed on the first page of the interview and the SUPPORT Follow-up Number written on subsequent pages in case the completed form pages are separated.

6.1 Conducting the Interview

6.1.1 Initiating the interview:

Script Introducing the Study:
N.B. The interviewer's script is in italics and enclosed in quotations.

"Premature babies are more likely than full term babies to have breathing problems after discharge from the NICU. The purpose of this study is to see whether or not the treatments your baby received as part of the SUPPORT Study improves your baby's breathing in the 18-22 months following the baby's due date.

As part of this study, we will contact you every 6 months or so to ask you questions about your baby's breathing. The questions will be about your baby's breathing symptoms, especially wheezing and coughing, and about your baby's need for medical visits and treatments for breathing problems.

By wheezing we mean an expiratory sound (a sound that is made when breathing out, not in) that comes from the chest, sometimes described as whistling or musical.

We have prepared a diary for you to help you keep track of your baby's breathing, especially breathing problems and treatments.

Give diary

To complete the diary, please record how often your baby has wheezing or coughing, whether your baby visited a doctor's office, emergency room or was hospitalized for breathing problems.

When we call, we'd like you to gather the diary and any medications or other information about your baby's breathing.

In order to help us understand your baby's breathing and risk for breathing problems at home, we'd like to ask you a few questions about your home and about whether breathing problems run in the family. As with all information we collect, the answers to these questions will be kept confidential."

Please confirm the study baby's identity.

"We will be discussing, patient name. He/she is a boy/girl born on birth date"
Question 1.
Child's Name:
Please enter the child's name including, nickname that he/she will be called.

Question 2.
Enter the date of the interview in "mm/dd/yyyy" format.

Question 3.
Child's Sex:
Please enter the child's sex.

Question 4.
Child's Birthdate:
Please enter to the child's birth date in "mm/dd/yyyy" format.

Please confirm the identity of the caretaker being interviewed.
Question 5.
"With whom am I speaking?
Question 5a.
What is your relationship to the baby?"

Please specify the primary caretaker's name and relationship to the infant using the relationship codes used in the Network Follow up Program, Appendix B.

Every effort should be made to interview the primary caretaker during this interview and all subsequent interviews (6, 12 and 18 months). If the mother resides in the same household as the child, the mother is the primary caretaker. If each caretaker has exactly 50% custody,

record as the primary caretaker, the person who comes in for the discharge. This person should answer all subsequent interviews, if possible.

APPENDIX B

RELATIONSHIP CODES

The following codes are used to identify the primary caretaker.

001 - Mother of Child
002 - Father of Child
011 - Husband, Significant Other (SO)(if different from 002)
012 - Wife, Girlfriend (if different from 001)
021 - Maternal grandmother
022 - Paternal (SO) grandmother
031 - Maternal grandfather
032 - Paternal (SO) grandfather
041 - Maternal aunt
042 - Paternal (SO) aunt
051 - Maternal uncle
052 - Paternal (SO) uncle
061 - Brother
062 - Step Brother
071 - Sister
072 - Step Sister
081 - Maternal female cousin
082 - Paternal (SO) female cousin
091 - Maternal male cousin
092 - Paternal (SO) male cousin
101 - Other maternal relative
102 - Other paternal (SO) relative
201 - Foster mother
202 - Foster father
301 - Adoptive mother
302 - Adoptive father
401 - Other non-relative
402 - Social worker/case worker
501 - Staff in congregate care
502 - Still hospitalized
504 - Unknown

Question 6.
Type of Interview:
Record whether the interview conducted face to face or by telephone.

Interview Begins
(N.B. The interviewer's script is in italics and enclosed in quotations)

Script: ***"At this time, we would like a little information about the environment in which your new child will grow up."***

Question 7.

"First, how many people normally live with you in your home for at least 6 months of the year?"

Enter the total number of household members. A household member is a person who spends more than 7 nights in the home over a two week period for at least 6 months of the year.

Question 8.

"After the first few months, will your child be sharing a room with other family members on a regular basis?"

Enter YES if child shares a room with another household member more than 7 nights in a 2 week period.

Question 8a.

If answer to 8 is YES: *"How many people will sleep in the same room with him/her?"* Please record how many people will sleep in the same room with the child.

Question 9.

"*How many rooms are there in your house, excluding closets and bathrooms?"* Record how many rooms in the space provided.

A room is a space within the house in which residents play, sleep, work or eat.

Question 10.

"Do you have any pets inside the home?"

If yes record, *"How many dogs in the home? Cats in the home? Do you have other pets in the home? What kinds? How many?"*

If interviewee reports pets, please record the number of dogs and cats separately. Group all other pets together and record total number of pets that are neither a dog nor a cat.

Question 11.

"Does your home or apartment have air conditioning or some kind of cooling?"

Please enter "Yes" or "No"

Question 11.a-11.c Please record whether family has air conditioning or evaporative cooling. If family uses another type of home cooling system, please answer YES and record type.

Question 12.

"How is your home heated?, With steam or hot water, with a gas furnace, with electricity, with a wood stove, or something else? "

Please prompt by reading each of the listed heating options. Record all heating methods used in the home or apartment. If more than one heating type is used, please record all heating types used. Steam or hot water heat uses upright radiators or baseboard units. A central gas furnace uses forced air vents that blow air into the room. Included in wood stove heat is use of a fireplace for heat, including fireplaces with energy conserving "inserts".

Question 13.

"What fuel is used most for cooking in your home?"

There is no need to prompt with each alternative cooking fuel. Please record one primary cooking method used in the home or apartment.

Scripting: "The next questions are about your baby's diet ....."

Question 14.
"Is your child receiving only breast milk, only formula, or both breast milk and formula?"
Record response

Question 14a.
If reply to 14 is only breast milk (choice #1),
"*Will the breast milk be supplemented with formula in the next 6 months?"*
Please record "Yes", "No" or "Don't Know

Question 14b.
"If so, when do you think the supplement will begin?"
Enter YES, if breast milk will be supplemented with formula. Enter the number of months from date of interview that breast milk will be supplemented with formula.

Scripting: "The next question are about your baby's care environment ....."

Question 15.
"Does the mother plan to work outside the home within the next year?"
Select from responses below.
1. Yes
2. No
3. Don't Know

Scripting: "The next questions are about smoke exposure....."

Question 16.
"Which one of the following 3 statements best describes the situation regarding smoking in your child's ***home?****.....Read all options to the interviewee before recording a response: Smoking is allowed in any common room of the home, smoking is limited to part of the house where the child rarely goes, there is no smoking inside at all?*

Question 16a.
If answer to question 16 is "there is no smoking in the house at all", then ask question 13a, *"Are there any exceptions to this situation?"*
If respondent reports any exceptions, record "Yes". If no, skip to question 17.

Question 16b.
If answer to 16a is "Yes", then ask question16b.
"Under what circumstances are the exceptions allowed?"
Record a brief response as free text.

Question 17.

"*Which one of the following 5 statements best describes the situation regarding smoking in your* ***car?****…. Read all options to the interviewee before recording a response: Smoking is usually or always allowed, smoking is sometimes allowed, smoking occurs in the car only when the child is not inside, there is no smoking inside the car*"

Record the response as it applies to the main automobile in which the baby rides. If family does not ride in a car (public transportation only or baby doesn't leave home), record response #1.

Questions 17a and 17b. Responses questions to17a and 17b are completed similarly to questions 16a and 16b.

Question 18.

"How often have you smoked since this child was born?"

Please record response, never means never, daily means at least once per day, record occasionally for any quantity between never and daily.

Question 19.

"Altogether, how many people in the child's home smoke?" _____people

Record the number of people who reside in the home (spend more than 7 out of 14 nights in the home) who smoke. Any smoker counts, whether they smoke in the home, outside the home or at some distant location.

Family History Form

Scripting: "In the next section, we'd like to know what breathing and allergy problems run in the family."

Administer the attached Family History Questionnaire using the follow script.

Mother:

"We'll start with the baby's mother. How old is the baby's biologic mother? Does she have bronchitis, emphysema, COPD, bronchiectasis, asthma, inhaled allergies, or food allergies?"

"Does she (you) have any other chronic respiratory illnesses?"

"How often do you smoke in the baby's home?"

Father:

"For the baby's biologic father, is he living? How old is he? Does he have bronchitis, emphysema, COPD, bronchiectasis, asthma, inhaled allergies, or food allergies?"

"Does he have any other chronic respiratory illnesses?"

"How often does he smoke in the baby's home?"

Complete the remainder of the table by collecting the same medical history using the script above.

Please complete a family history for each of the family relationships listed, mother, father, maternal grandmother (Mom's biologic Mother), maternal grandfather (Mom's biologic Father), paternal grandmother (Dad's biologic Mom), and paternal grandfather (Dad's biologic Father). For each relative above, enter whether they have ever had any of the listed respiratory problems. The interviewer need not explain each diagnosis, but may offer an explanation if asked. Record only those responses that pertain to the baby's biologic relatives.

Question 20.

"Finally, which friend or relative is most likely to be able to contact you 6 months from now in case we lose contact with you?"

Record the information for an alternate contact person who is unlikely to move and the most likely to know the baby's family most recent residence / phone number.

Chapter 7
6 and 12 Month Pulmonary Outcome Questionnaires

Introduction

The purpose of this questionnaire is to obtain an **interval** respiratory history, such that when the 6, 12 and 18-22 month questionnaires are taken together, a complete respiratory history over the time period is collected.

The questionnaire will be administered to the parent or guardian by a certified telephone interviewer at 6 months' CA and again at 12 months' CA.

Centers choosing Option 1 will administer the questionnaire using a certified local interviewer and locally maintained contact information. For centers choosing Option 2, a Rochester Health Services Research Group (RHSRG) certified interviewer will conduct the interview via long distance telephone call using contact information maintained by the local center and faxed or emailed to the RHSRG.

Instructions for Completing the 6 and 12 Month Questionnaire (SUPF02)

Instructions for Completing the NICU Discharge-Baseline Interview (SUPF01)

Timing of the Interview:

This interview should be administered by a certified study interviewer. The target window for this interview is at the following corrected ages: 6 months ± 2 weeks and 12 months ± 2 weeks, with an acceptable window of 6 months ± 1 month and 12 months ± 1 month. If for any reason the infant is enrolled into the Pulmonary Outcome Study later than this time window or becomes available for a Pulmonary Outcomes Interview outside this window, the questionnaire should be administered, collecting an interval history from the time of NICU discharge or the most recent interview, whichever is most recent.

Heading- Infant's Identification
The following information is included in the heading section of all patient specific data forms: Center, Site, Network Number, SUPPORT Follow-up Number, Birth Number and Mother's Initials **(optional).** This information should be completed on the first page of the interview and the SUPPORT Follow-up Number written on subsequent pages in case the completed form pages are separated.

7.1 Conducting the Interview

7.1.1 Initiating the interview:

Please request and confirm the identity of the caretaker who completed the initial interview.

Every effort should be made to interview the primary caretaker who completed the initial interview (hereafter referred to as the primary respondent) during this interview and all subsequent interviews (6, 12 and 18 months). If the mother resides in the same household as the child, the mother is the primary caretaker. If each caretaker has exactly 50% custody,

record as the primary caretaker, the person who comes in for the discharge. This person should answer all interviews, if possible.

The interviewer will need to ask for the primary respondent. In the event that the primary respondent is not available, arrangements should be made to call back at a time when the primary respondent will be free to complete the interview. At least 3 call attempts should be made to reach the primary respondent, after that a secondary respondent, who is familiar with the baby and his or her respiratory health, can be identified to complete the interview.

Introduction Script:
When parent or primary care giver is on phone:

"Hello, my name is <your name>. I am calling from the <NICHD Center>. As you probably remember, when you were in the NICU you enrolled in our study about respiratory health of premature infants. I am calling to ask you some questions about your baby's breathing. It will take about 10-20 minutes to complete. Is this a good time for you?"

"Before we begin this interview, it would be helpful if you could gather the breathing diary given to you when you left the NICU as well as any medications your child has been prescribed or has been taking and have them in front of you. As with all information we collect, the answers to these questions will be kept confidential."

Question 1.
Please enter date of the interview.

Please confirm the identity and contact information for the study baby to be interviewed.

"We will be discussing, patient name. He/she is a boy/girl born on birth date"
Child's Name:
Please enter the child's name.

Child's Birthdate:
Enter to the child's birth date in "mm/dd/yyyy" format.

Child's Telephone Number:
Enter the telephone number to the child's home.

Child's Address:
Enter the address of the child's home.

Alternate Contact Information
Which friend or relative is most likely to be able to contact you 6 months from now in case we lose contact with you?"

Confirm the contact information for an alternate contact person who is unlikely to move and the most likely to know the baby's family most recent residence / phone number.

Question 2a. and 2b.
Enter name and relationship code of the person being interviewed.

Please specify the primary caretaker's name and relationship to the infant using the relationship codes used in the Network Follow up Program.

Question 3.
Type of interview.

Please specify and record whether the interview was administered face to face or via telephone.

Question 4.
Location of Interview.

Please specify and record whether the interview was administered at the local center (Option 1) or by the Rochester site (Option 2).

Instructions:
Parents or guardians expressing concerns regarding their child's breathing should be advised to discuss them with the family's primary care physician.

Where the phrase "last contact" is used below, please substitute with the most specific relevant time prompt, e.g. for the 6 month interview, refer to "since NICU discharge"; for the 12 month interview, refer to "over the past 6 months", etc.

Interview begins:
(N.B. The interviewer's script is in italics and enclosed in quotations)

Scripting:
"Some of these questions will be familiar to you. Since we last spoke (__ __) months ago on (__ __/__ __/__ __) we want to learn what changes, if any, there have been to your child's health. We are especially interested in any breathing problems your child may have....."

Question 5.
"Has the child been with you during the past 6 months?"

Please enter "Yes" or "No". If child has been with the interviewee less than 6 months, please enter "No".

Scripting: "Since <our last contact> with you about your child....."

Please replace the phrase "our last contact", with an interview specific prompt, e.g. "since discharge from the NICU" at the 6 month interview or "since our telephone conversation 6 months ago", for the 12 and 18 month interviews. Equivalent phrases may be used.

Question 6.
"How many times has your child visited a doctor's office?" |___|___| times

Record the number of times that the baby visited the doctor's office for any reason.

Question 6a.
"How many of these times were because of wheezing or breathing problems?"

Record the number of times that the baby visited the doctor's office with breathing problems as one of the 2 major concerns for the visit.

Scripting: "Since <our last contact> with you about your child....."

Please replace the phrase "our last contact", with an interview specific prompt, e.g. "since discharge from the NICU" at the 6 month interview or "since our telephone conversation 6 months ago", for the 12 and 18 month interviews. Equivalent phrases may be used.

Question 7.

"How many times has your child visited an Emergency Department (Emergency room)?"

|___|___| times

Record the number of times that the baby visited the emergency department or emergency room for any reason.

Question 7a.

"*How many of these times were because of wheezing or breathing problems?*"

Record the number of times that the baby visited emergency services with breathing problems as one of the 2 major concerns for the visit.

Question 8.

"How many times has your child stayed in the hospital for 1 or more nights in a row?"

|___|___| times

Record the number of times the baby was hospitalized for any reason, i.e the number of hospitalizations, not the number of hospitalized days.

Question 8a.

"How many of these times were because of wheezing or breathing problems?" |___|___| times

Record the number of times that the baby was hospitalized with breathing problems as one of the 2 major concerns for the visit.

Script:

"The next questions are about your baby's breathing. .....

The first question is about wheezing. By wheezing we mean an expiratory sound (a sound that is made when breathing out, not in) that comes from the chest, sometimes described as whistling or musical."

Question 9.

"Since <our last contact> with you, has your baby's chest sounded wheezy or whistling?"

Enter yes if the respondent reports that the baby's chest has sounded wheezy or whistling. The interviewer may repeat the verbal and audio descriptions of wheezing may be repeated to the respondent. If respondent answers "I don't know", interviewer should ask respondent to think back over the time period, repeating the description. If parent is still not sure, record "don't know".

Question 9a.

"Has your baby's breathing sounded like this?" ***(play audio clip of wheezing).***

This question is intended for all respondents, regardless of whether they reported wheezing in question 9. The audio clip is from a patient with severe, audible wheezing and represents only one of many manifestation of wheezing breathing sounds. If asked, the interviewer may say that this represents just one type of wheezing. We wish to know about all wheezing and therefore we asked two questions.

Record response, "Yes" or "No". If respondent replies "no" or "don't know", interview skips to question 10. If yes, proceed to questions 9b-g.

Question 9b.

"Has this occurred with colds?"

A "cold" is an upper respiratory infection; other phrases for a "cold" include, "head cold", "rhinitis, "runny or water nose" or "sniffles". A cold may be complicated by an otitis media (ear infection).

A "cold" does not include "chest cold", "bronchitis", "pneumonia", or "bronchiolitis".

Question 9c.

"Has your child's chest sounded wheezy or whistling apart from colds?"

Enter "yes" if the baby had wheezy or whistling in the chest at a time when he / she did not have a cold.

Question 9d.

"During what month did your child's chest first sound wheezy or whistling?"

_____ month ____ year

Please record the month and year during which the child's chest first sounded wheezy or whistling. The respondent may indicate the child's age at which the child's chest first sounded wheezy or whistling. The interviewer should record the month and year of the event.

Here the month and year, rather than the age, that the symptoms began is recorded in an effort to avoid confusion regarding chronologic and corrected ages.

The next 4 questions use similar phrases and the same response options. Please emphasize the phrases which are unique in each question ("on average" or "worst two week period", "daytime" or "nighttime"). If the respondent gives the same response to 5e as 5f, please confirm with the respondent that 5e refers to "on average" and that 5f refers to the "worst two week period".

Question 9e1.

*"Over the past 6 months, **on average**, how often has your child's chest sounded wheezy or whistling during the daytime? Would you say never, twice a week, more than 2 times a week, but not every day, every day, but not all the time, everyday, all the time."*

Record response. Interviewer may repeat the choices or help respondent settle upon the choice.

Question 9e2.

*"Over the past 6 months, **on average**, how often has your child's chest sounded wheezy or whistling during the nighttime? Would you say never, twice a week, more than 2 times a week, but not every day, every day, but not all the time, everyday, all the time."*

Record response. Interviewer may repeat the choices or help respondent settle upon the choice.

Question 9f1.

*"Over the past 6 months, **during the worst 2 week period,** how often has your child's chest sounded wheezy or whistling during the daytime? Would you say never, twice a week, more than 2 times a week, but not every day, every day, but not all the time, everyday, all the time."*

Record response. Interviewer may repeat the choices or help respondent settle upon the choice.

Question 9f2.

*"Over the past 6 months, **during the worst 2 week period,** how often has your child's chest sounded wheezy or whistling during the nighttime? Would you say never, twice a week, more than 2 times a week, but not every day, every day, but not all the time, everyday, all the time."*

Record response. Interviewer may repeat the choices or help respondent settle upon the choice.

Question 9g.

"Since our last contact with you, has your child taken any medicine prescribed by a doctor for wheezing?"

Record "Yes" or "No".

Question 10.

"Since our last contact with you, has your child had a cough when he/she did not have a cold?"

Record whether the baby coughs when otherwise well. Do not include coughing associated with eating, drinking or choking. See question 9 for clarification of phrase "cold".

Question 10a.

"At what time of the day has this cough usually occurred? In the morning; shortly after rising; later in the day; during the night; no relation to time of day?"

Interviewer should read all responses to the respondent and circle all that apply.

Question 10b.

"Has he/she coughed on most days for as much as 2 to 3 months?"

Please record "Yes" or "No"

Question 10c.
"During what month did your child first develop the cough?"
Record month and year that the cough first developed, when the respondent recognized the cough whether or not they view it as a problem.

Question 10d.
"Has your child's chest ever sounded wheezy or whistling with episodes of coughing?"
Record yes if the respondent associates wheezing or whistling breath sounds with the presence of the cough.

Questions 10e1-10f2. Questions 10e1-10f2 are completed similarly to questions 9e1-9f2.

Question 11.
*"Over the past 6 months, **on average**, how many **days per month** did you have to change your daytime or evening plans because of your child's breathing problems:"*
Please record the number of days that the respondent reports having to change plans because the baby's breathing is different from baseline. An example of a changed plan includes withholding the baby from a planned daycare or babysitting situation because he / she is wheezing.

This does not include preventive avoidance, such as avoiding social situations or trips because the baby might get sick or may be exposed to another child. The interviewer may assist the respondent in selecting a number by establishing a range, then having the respondent select a specific answer.

Question 12.
*"Over the past 6 months, **during the worst 2 week period**, how many **days** did you have to change for daytime or evening plans because of your child's breathing problems:"* |___|___| # of days
Interviewer should emphasize the "worst 2 week period". Record response using criteria similar to those in Question 11.

The next 4 questions relate to respiratory diagnoses that may be associated with wheezing and airway dysfunction, either directly, as secondary symptom or as a condition that may be confused with airway dysfunction.

Question 13.
"Since our last contact with you, has your child had asthma or reactive airways disease diagnosed by a doctor?"
Record response, either "Yes" or "No". If respondent does not recognize the condition, record "No".

Question 14.
"Since our last contact with you, has your child had bronchiolitis, bronchitis, or pneumonia diagnosed by a doctor?"

Record response, either "Yes" or "No". If respondent does not recognize the condition, record "No".

Question 15.
"Since our last contact with you, has your child had croup diagnosed by a doctor?"
Record response, either "Yes" or "No". If respondent does not recognize the condition, record "No".

Script: "The next question are about your baby's diet....."

Question 16.
"In the past 6 months, did your baby receive mother's breast milk, either at breast, from a bottle or through a tube?"
If baby received any breast milk, record "Yes".

If yes to Question 16, answer question 16a and 16b, if "No", skip to Question 17:

Question 16a.
"For how many months did your child receive breast milk? Would you say? ....Less than 1 month, 1-3 months, 4-6 months?"
Record duration of time that the baby received any breast milk.

Question 16b.
"For how many months did your child receive breast milk <u>for more than half of his/her feedings</u>? Would you say... Less than 1 month, 1-3 months, 4-6 months?"

Record duration of time that the baby received more than ½ of feedings from breast milk, provided by any route.

A mother who fed her infant breast milk 25% of the time and formula 75% of the time, weaning the baby at 4 months, would answer "yes" to question 16, "4-6 months" to question 16a, and "less than 1 month" to question 16b.

Script: "***The next questions are about smoke exposure.....***"

Question 17.
*"Which of the following 3 statements best describes the situation regarding smoking in your child's **home?**..... Read all options to the interviewee before recording a response: Smoking is allowed in any common room of the home, smoking is limited to part of the house where the child rarely goes, there is no smoking inside at all?"*

Question 17a.
If answer to question 17 is "there is no smoking inside at all", then ask question 17a,
"Are there any exceptions to this situation?"
If respondent reports any exceptions, record "Yes". If no, skip to question 18.

Question 17b.
If answer to 17a is "Yes", then ask question17b.

"Under what circumstances are the exceptions allowed?"
Record a brief response as free text.

Question 18.
"*Which of the following 5 statements best describes the situation regarding smoking in your* ***car?****.... Read all options to the interviewee before recording a response: Smoking is usually or always allowed, smoking is sometimes allowed, smoking occurs in the car only when the child is not inside, there is no smoking inside the car"*

Record the response as it applies to the main automobile in which the baby rides. If family does not ride in a car (public transportation only or baby doesn't leave home), record response #1.

Question 18a and 18b. Responses questions to 18a and 18b are completed similarly to questions 17a and 17b.

Question 19.
'How often has the mother or primary caregiver smoked since your child was born?'

If speaking with the mother, please substitute "you" for "mother or primary caregiver". Record response based on occurrence of any smoking activity, regardless of where it takes place. Record "Never" if the mother or primary care giver has never smoked anywhere since the baby was born, record "Daily" if she /he smokes daily in any location, and record "Occasionally" if response is neither "Never" nor "Daily".

Question 20.
"How many people in the child's home smoke?" |___|___| people

Record response based on occurrence of any smoking activity, regardless of where it takes place.

Script: *"The next questions are about your home and your babysitter's home or day care"*

Question 21.
"Approximately how many hours per week does your child spend at a babysitter's home or day care?" |___|___| hrs If 0 skip to question 22.

Record the number of hours that the baby spends outside his/her home, regardless of whether this is in the home of another parent, grandparent, or friend.

Question 21a.
If response to question 21 is greater than 0,
"How frequent is there smoke exposure at the babysitter or daycare?"

Record response based on occurrence of any smoking activity, regardless of where it takes place. Record never if there is no smoking allowed inside the babysitter or daycare provider's edifice in any location, record daily if smoking occurs inside the edifice daily in any location, and record occasionally if response is neither never nor daily.

Question 21b.
"How many children beside your baby are in the daycare?"

Record the average number of children less than 12 years of age who inhabited the babysitter or daycare over the past 2 weeks when the baby was present.

Question 22.
"How many children under 12 live in your house?" |___|___| children
Record number of children who spend more than 7 nights in the home over a two week period.

Question 23.
"Do you have any pets inside the home?"
Record "Yes" or "No"

Question 23a. If yes record,
"How many dogs? Cats? Do you have other pets? What kinds? How many?"

If respondent reports pets, please record the number of dogs and cats separately. Group all other pets together and record total number of pets that are neither a dog nor a cat.

Script: "*The last questions involve respiratory treatments that your baby may receive.....*"

Question 24.
"Has your child had RSV shots (palivizumab) to prevent Respiratory Syncytial Virus (Synagis, palivizumab, RSV shot)?"
Record respondent's answer, "Yes", "No" or "Don't know". If respondent does not recognize the treatment, record "Don't Know".

Question 25.
"Has your child had a flu shot?"
Record respondent's answer, "Yes", "No" or "Don't know". If respondent does not recognize the vaccine, record "Don't Know".

Question 26.
"Is your child on any oxygen therapy at home?"
Record respondent's answer, "Yes" or "No". If respondent does not know, the interviewer should prompt further by asking, "does your baby use any oxygen equipment, such as an oxygen tank, at home?"

Question 26a – 26c.
These questions can be answered using the following script.

If response to question 26 is "Yes",
"What device is used to provide the oxygen?.....Oxygen hood, nasal cannula or ventilator?"
Record response in checkbox provided.

If response to question 26 is "Yes", the interviewer should ask,
"*What percent oxygen does your baby use?"*

Record response as fraction inspired oxygen (FiO2) in the space adjacent to the oxygen delivery device. For example, room air (ambient air) is 21% oxygen, enter as FiO2 value of 0.21

If response to question 26 is either "nasal cannula" or "oxygen hood", interviewer asks, *"How many liters of oxygen does the baby receive?"*

Record value as liters per minute (1cc is .001liters, 1/8 liter is 0.125 liters, ¼ liter is 0.25 liters, etc.)

MEDICATIONS

Script: *"The last two questions involve the medicines your child is taking for breathing problems....."*

Question 27.
"What medicines has your baby taken over the past 6 months, including medicines delivered by a nebulizer or breathing machine?"

For this question, record all respiratory related medications. Record a written response in the table and later, after the interview, record the medication code from the table below. Medications that do not appear on the list are unlikely to be used to treat respiratory conditions in this age group. Do not prompt for each medication in the medication list.

Chapter 8
18-22 Month Questionnaire

Introduction

The purpose of this questionnaire is to obtain an **interval** respiratory history and to identify a history of atopy that may increase the likelihood of symptomatic airway dysfunction. Questions are designed to ascertain the frequency and severity of wheezing and cough episodes and to assess the need for outpatient pulmonary care. In addition, risk factors obtained at the 1st interview will be confirmed. There are a total of 30 questions, encompassing questions from the discharge, 6 month and 12 month questionnaires.

This interview will be conducted at 18-22 months' corrected age, either by the local NICHD Follow Up Program (Option 1) or long distance from Rochester (Option 2), based on center preference.

Instructions for Completing the 18-22 Month Questionnaire (SUPF03)
Timing of the Interview:
The target window for this interview is between 18 and 22 months' corrected age. If for any reason the infant is enrolled into the Pulmonary Outcome Study at this time window or becomes available for a Pulmonary Outcomes Interview outside this window, the questionnaire should be administered, collecting an interval history from the time of NICU discharge or the most recent interview, whichever is most recent.

This interview should be administered by a certified study interviewer either by telephone prior to the regularly scheduled 18-22 month NICHD developmental follow-up clinic visit or face to face at the time of the visit.

Heading- Infant's Identification
The following information is included in the heading section of all patient specific data forms: Center, Site, Network Number, SUPPORT Follow-up Number, Birth Number and Mother's Initials **(optional).** This information should be completed on the first page of the interview and the SUPPORT Follow-up Number written on subsequent pages in case the completed form pages are separated.

8.1 Conducting the Interview

8.1.1 Initiating the interview:

The 18-22 month questionnaire is conducted in the same fashion as for the 6 and 12 month interviews. In addition to the 27 questions included in the 6 and 12 month questionnaires, the 18-22 month questionnaire includes 7 questions about allergies.

See Chapter 8 of the manual of procedures for directions to administer questions 1-28 of the 18-22 month questionnaire. Directions for questions 28-34 begin here.

Script: "*The last questions regard allergies.....*"

Question 28.

*"**During the past year**, for how many days has your child been unable to do his/her usual activities because of illnesses such as chest (not head) colds, bronchitis, asthma or pneumonia? 0-3 per year, 4-5 per year, 6-9 per year, more than 9 per year?"*

Question 29.

*"How many head colds (common colds) **per year** does your child usually have? Would you say…0-3 per year, 4-5 per year, 6-9 per year, more than 9 per year?"*

Question 30.

*"Has your child **ever** had hay fever or any other condition that makes his/her nose runny, stuffy, or itchy **apart** from colds?"*

Record response, either "Yes" or "No". If respondent does not recognize the condition, record "No".

Question 31.

*"Has your child **ever** had allergies which cause nose, eye or lung problems?"*

Record response, either "Yes" or "No". If respondent does not recognize the condition, record "No".

Question 32.

*"Has your child **ever** been allergic to any food?"*

Record response, either "Yes" or "No". If respondent does not recognize the condition, record "No".

Question 33.

*"Has he/she **ever** been allergic to any medicine?"*

Record response, either "Yes" or "No". If respondent does not recognize the condition, record "No".

Question 34.

*"Has your child **ever** had eczema (allergic skin rash)?"*

Record response, either "Yes" or "No". If respondent does not recognize the condition, record "No".

Question 34a.

If Question 34 is "Yes",

"Was this diagnosed by a doctor?"

Record response, "Yes" or "No"

APPENDIX A
List of Acronyms

BOOST Trial – Benefits of Oxygen Saturation Targeting
BPD – Bronchopulmonary Dysplasia
CA – Corrected Age
CLD – Chronic Lung Disease
CPAP – Positive pressure applied with a face mask to help keep lungs inflated
FEF – Forced Expiratory Flow
GA – Gestational Age
GDB – Generic Data Base for the NICHD Neonatal Research Network
HDMA – House Dust Mite Allergen
HIPPA – Health Insurance Portability and Accountability Act of 1996
HSR Group – University of Rochester Health Services Research Group
IRB – Institutional Review Board
LBW – Low Birth Weight
NBW – Normal Birth Weight
NHLBI Consensus Expert Report -
NICHD – The National Institute of Child Health and Human Development
NICU – Neonatal Intensive Care Unit
PFT – Pulmonary Function Testing
RDS – Respiratory Distress Syndrome
ROP – Retinopathy of Prematurity
RSV - Respiratory Syncytial Virus

SAMPLE CONSENT FORMS

SAMPLE CONSENT FORM FOR PATIENTS ENROLLED IN SUPPORT

TITLE: SUPPORT Trial Pulmonary Outcomes Study- Follow-up Study of Infants Enrolled in the NICHD Neonatal Research Network SUPPORT Trial

PRINCIPAL INVESTIGATOR: Timothy P. Stevens, MD MPH

CO-PRINCIPAL INVESTIGATOR: Dale L. Phelps, MD

INTRODUCTION and BACKGROUND:
This consent form describes a research study and what you may expect if you decide to have your infant participate. You are encouraged to read this consent form carefully and to ask the person who presents it any questions you may have before making your decision whether or not to have your infant participate.

This form describes the known possible risks and benefits in the study. You are completely free to choose whether to participate.

Your infant is invited to be a part of this research project because (s)he is a premature baby who is a member of the National Institutes for Child Health and Human Development (NICHD) Neonatal Research Network SUPPORT Trial. As described in the SUPPORT Trial Consent that was discussed with you previously, the SUPPORT Trial is designed to find out more about treatment with CPAP (positive pressure applied with a face mask to help keep the lungs inflated) and learn the appropriate levels of oxygen saturation (oxygen levels in the blood) in premature babies. The SUPPORT Study will determine the effect of these treatments on your baby's respiratory and visual health prior to discharge from the Neonatal Intensive Care Unit (NICU).

However, we know that many babies born as early as your baby are at risk for breathing problems, especially wheezing and coughing during early childhood, after discharge from the NICU.

PURPOSE:
The purpose of Pulmonary Outcomes Study described here is to determine the effect of the SUPPORT Study treatment on your baby's respiratory health in early childhood, during the first 18-22 months after his/her expected delivery at full term.

PROCEDURES:
You and your infant's participation will begin with an interview before your infant is discharged from the hospital or at the time of your regular follow-up visit with the NICU Outpatient Clinic. At this interview we will ask you questions about your family, including questions about family history of breathing problems, and questions about your home, including things that may

increase your child's risk of breathing problems. You do not need to answer any questions that make you uncomfortable. The interview will take about 15 minutes.

We will continue to stay in touch with you and your infant by telephone or in person at one of your visits (((**Customize language here based on which option your center chose for administering the questionnaires**))) every 6 months over the next 18-22 months, a total of three times. At these times, we will ask questions about your child's breathing (especially wheezing and coughing), medication use, and visits to a Doctor, Emergency Room, or Hospital visits for treatment of breathing problems. We will also ask you several questions about your family and yourself. The entire call should take about 15 minutes of your time, less if your baby has had no breathing problems.

We will schedule the telephone calls at a time that is convenient for you. The telephone calls will occur when your infant is 6, 12, and 18 months after his/her expected delivery at full term.

The results from your baby's questionnaire will be combined with other infants from around the country. However, your baby's name will not be used.

We also ask your permission to contact your baby's Doctor to obtain their assessment of your baby's breathing and need for breathing treatments.

NUMBER OF PARTICIPANTS:
All babies who participate in the SUPPORT Trial will be offered the opportunity to participate in this study. There will be close to 1300 infants enrolled in the SUPPORT Trial. We hope that as many as possible will choose to participate in this study to help determine the long-term effect of the SUPPORT Study treatments. Approximately 40 babies will be enrolled locally.

RISKS AND DISCOMFORTS:
You may experience anxiety or psychological discomfort while completing these questionnaires and/or the interviews. You are free to choose not to answer any question for any reason.

BENEFITS:
The major benefit to you and your infant is that actual or potential breathing problems experienced by your baby could be identified early and brought to the attention of your baby's Doctor for treatment.

CONFIDENTIALITY OF RECORDS AND HIPAA AUTHORIZATION
While we will make every effort to keep information we learn about you private, this cannot be guaranteed. Other people may need to see the information. While they normally protect the privacy of the information, they may not be required to do so by law. Results of the research may be presented at meetings or in publications, but your name will never be used.

The federal Health Insurance Portability and Accountability Act (HIPAA) requires us to get your permission to use health information about you that we either create or use as part of the research. This permission is called an Authorization. We will use your child's research record, related information from your child's medical records, results of laboratory and other diagnostic tests obtained during his/her initial hospitalization, as well as the information and test results obtained during the telephone interviews of your baby's breathing.

We will use your child's health information to conduct the study, to monitor your child's respiratory status and to determine long term effects on breathing of the SUPPORT Study treatments. Health information is used to report results of research to sponsors and federal regulators. It may be audited to make sure we are following regulations, policies and study plans. If you have never received a copy of the Strong Health HIPAA Notice, please ask the investigator for one. To meet regulations or for reasons related to this research, the study investigator may share a copy of this consent form and records that identify you with the following people: The Department of Health and Human Services, the University of Rochester, the NICHD Neonatal Research Network and organizations (like RTI International) used by NICHD to manage studies.

If you decide to have your child take part, your Authorization for this study will not expire unless you cancel or revoke it. You can always cancel this Authorization by writing to the study investigator. If you cancel your Authorization, your child will be removed from the study. However, standard medical care and any other benefits to which you are otherwise entitled will not be affected. Canceling your Authorization only affects uses and sharing of information after the study investigator gets your written request. Information gathered before then may need to be used and given to others. For example, information gathered during your child's initial hospitalization will be sent to the NICHD Neonatal Research Network and to RTI International.

As stated in the section on Voluntary Participation below, you can also refuse to sign this consent/Authorization and not be part of the study. You can also tell us you want to leave the study at any time without canceling the Authorization. By signing this consent form, you give us permission to use and/or share your health information.

COSTS:
There is no cost to you to participate in the study.

CONTACT PERSONS:
For more information about this research, or if you believe your infant has suffered a research-related injury, please contact Timothy P. Stevens, MD MPH or Dale L. Phelps, MD (Principal Investigators) at (585) 275-2972. You can also reach them, or one of the other attending physicians, by asking the unit secretary in the NICU to page them.

If you have any questions about your rights as a research subject, you may contact the Human Subjects Protection Specialist at the University of Rochester Research Subjects Review Board at Box 315, 601 Elmwood Avenue, Rochester, NY 14642-8315. Telephone: (585) 276-0005, for long-distance you may call toll-free, (877) 449-4441.

VOLUNTARY PARTICIPATION:
Taking part in this study is entirely voluntary. You are free not to participate or to withdraw at any time, for whatever reason, without risking loss of present or future care you would otherwise expect to receive. In the event that you do withdraw from this study, the information you have already provided will be kept in a confidential manner.

SIGNATURES/ DATES:

I have read (or have had read to me) the contents of this permission form and have been

encouraged to ask questions. I have received answers to my questions. I give permission for my child to participate in this study. I will receive a signed copy of this form for my records and future reference.

SAMPLE CONSENT FORM FOR FUTURE SUPPORT PATIENTS

Consent to Act as a Research Subject

The Surfactant Positive Airway Pressure and Pulse Oximetry Trial in Extremely Low Birth Weight Infants

The SUPPORT Trial of the NICHD Neonatal Research Network

Neil Finer, MD, his associates, and the National Institutes for Child Health and Human Development (NICHD) Neonatal Research Network are conducting a research study to find out more about treatment with CPAP (positive pressure applied with a face mask to help keep the lungs inflated) and learn the appropriate levels of oxygen saturation (oxygen levels in the blood) in premature babies. You are being asked to allow your child to be in the study because there is a possibility he/she will be born between 16 and 12 weeks early (24-28 weeks gestational age).

The purposes of this trial are the following:
1) To compare infants who receive delivery room CPAP and who have strict guidelines for having a breathing tube placed with infants who have the tube placed and surfactant (a liquid which helps babies with immature lungs breath easier by helping keep their lungs from collapsing) given in the delivery room.
2) To compare low range (85-89%) oxygen saturation levels with high range (91-95%) levels to determine if a lower range results in decreased ROP (Retinopathy of Prematurity, an eye disease that may result in impairment of vision or even blindness, which may be caused by excessive levels of oxygen.)

Duration of the Study: We expect to include about 1300 babies in the study from all the NICHD Neonatal Research Network hospitals over a two-year period.

The use of CPAP and Intubation/Surfactant are both treatments currently used in the delivery room at UCSD. The decision as to which to use is currently made by the physician attending the delivery.

The oxygen level currently used in the NICU at UCSD is between 85% and 95%. Both treatment groups (85-89% and 91-95%) fall within that range. The study will attempt to keep babies in one of these two smaller ranges.

If you agree to allow your child to be in this study, the following will happen to your child: Prior to delivery, and after your permission, your baby will be randomized (chosen by chance like the flip of a coin) to one of two lung treatment strategies. The treatments are as follows:
1) CPAP in the delivery room immediately after birth and continuing in the NICU, or
2) The placement of a tube in his/her trachea (windpipe) in the delivery room followed by surfactant administration and ventilation (breathing for the baby using a machine).

In addition to being randomly assigned to one of the two groups described above, your baby will be randomized to a High reading or Low reading oximeter (a monitor that displays how

much oxygen is in the blood). The oximeters (oxygen monitors) used in this trial are FDA approved oximeters which have been modified for research purposes. This modification makes the monitors show a value which is either slightly higher or slightly lower than the true oxygen level when values are between 85 and 95%. Outside those ranges, the oximeter works the same as the standard of care device.

Which group your baby is randomized to will not be known to the nurse taking care of your baby, or his/her physician. Only the study coordinator will know which group your baby is in. Within the range of oxygen which we normally keep babies in, your baby will either be on the high end of normal or the low end of normal. He/she will remain on this device until he/she reaches 36 weeks adjusted age. (e. g. 24 wks gestation plus 12 weeks of age = 36 weeks adjusted age). Other care will be conducted as normal during his/her participation in the study.

We will continue to stay in touch with you and your infant by telephone or in person at one of your visits ((((Customize language here based on which option your center chose for administering the questionnaires)))) every 6 months over the next 18-22 months, a total of three times. At these times, we will ask questions about your child's breathing (especially wheezing and coughing), medication use, and visits to a Doctor, Emergency Room, or Hospital for treatment of breathing problems. We will also ask you several questions about your family and yourself. The entire call should take about 15 minutes of your time, less if your baby has had no breathing problems.

We will schedule the telephone calls at a time that is convenient for you. The telephone calls will occur when your infant is 6, 12, and 18 months after his/her expected delivery at full term.

The results from your baby's questionnaire will be combined with other infants from around the country. However, your baby's name will not be used.

Participation in this study may involve some added risks or discomforts. Because all of the treatments proposed in this study are standard of care, there is no predictable increase in risk for your baby. Infants randomized to the CPAP group may, at some point in their care, require intubation and assisted ventilation (methods to help them breathe). If the attending physician deems this necessary, participation in the study will not affect this decision. Some unknown risks may be learned during the study. If these occur, you will be informed by the study personnel. The only other risk of this study is the risk to confidentiality. Every effort will be made to keep your child's medical record confidential. There will be no name or other patient identification in any study report that may be published after the study is completed. Measures taken to protect you and your baby's identity are described in the confidentiality section of this document.

There may be benefits to your child directly, including a possible decrease in chronic lung disease (need for extra oxygen near discharge) or wheezing in the first 2 years and/or a decrease in the need for eye surgery as a result of exposure to oxygen. Because we do not know in advance the actual strategies chosen for your child, or which of the treatment strategies is the most effective, it is also possible that your baby will receive no direct benefit. The knowledge learned from this study may help us treat babies in the future. However, as noted above, each of the 4 possible combinations of treatments is considered by some units to represent their desired approach.

If your child is injured as a direct result of participation in this research, the University of California will provide any medical care your child needs to treat those injuries. The University will not provide any other form of compensation to you if your child is injured. You may call the UCSD Human Research Protections Program office at (858) 455-5050 for more information about this, or to inquire about your rights as a research subject, or to report research-related problems.

_____ has explained this study to you and answered your questions. If you have other questions or research-related problems, you may reach Wade Rich, the Study Coordinator, or Renee Bridge, the Research Nurse, at 619-543-6560. You may contact the principal investigator Dr. Neil Finer at 619-543-3794

As an alternative to participation in this study you may decide to have your baby's doctor decide which treatment your baby will receive. If you decide not to include your child in this study, none of his/her medical information will be included in the study data. Participation in research is entirely voluntary. You may refuse to participate or withdraw at any time without jeopardy to the medical care your child will receive at this institution of other loss of benefits to which your child is entitled. If you withdraw your child from the study, the attending physician will decide whether to maintain current treatment or change it, based on your child's needs at the time of the decision. Data collection for research purposes will stop at that time.

Clinical information will be collected from your baby's chart by study personnel at UCSD. Information will be labeled with a code number. Coded information will be sent to the NICHD Neonatal Network's Data Coordinating Center at RTI International in Research Triangle Park, North Carolina. The study log linking the code number with your baby's identity will be kept under lock and key at UCSD. Information directly identifying your baby will not leave UCSD. Research records will be kept confidential to the extent provided by law.

You may withdraw your child from the study for any reason. In addition, the study doctors may decide to withdraw your child if they feel it is in his/her best interest to do so. You have received a copy of this consent document to keep and the Experimental Subject's Bill of Rights.

You agree to have your child participate.

APPENDIX D
RELATIONSHIP CODES

The following codes are used to identify the primary caretaker.

001 - Mother of Child
002 - Father of Child
011 - Husband, Significant Other (SO)(if different from 002)
012 - Wife, Girlfriend (if different from 001)
021 - Maternal grandmother
022 - Paternal (SO) grandmother
031 - Maternal grandfather
032 - Paternal (SO) grandfather
041 - Maternal aunt
042 - Paternal (SO) aunt
051 - Maternal uncle
052 - Paternal (SO) uncle
061 - Brother
062 - Step Brother
071 - Sister
072 - Step Sister
081 - Maternal female cousin
082 - Paternal (SO) female cousin
091 - Maternal male cousin
092 - Paternal (SO) male cousin
101 - Other maternal relative
102 - Other paternal (SO) relative
201 - Foster mother
202 - Foster father
301 - Adoptive mother
302 - Adoptive father
401 - Other non-relative
402 - Social worker/case worker
501 - Staff in congregate care
502 - Still hospitalized
504 - Unknown

APPENDIX E
BREATHING DIARY

APPENDIX F
CONTACT INFORMATION TEMPLATE

All centers (Option 1 and 2 centers) will track their own patient's telephone and contact information for the purpose of administering telephone questionnaires at 6, 12 and 18-22 months.

The following core set of contact information is recommended for all enrolled patients.

For option 2 centers, use template to fax or email patient contact information to the Rochester site.

Network number: _____

Patient Name: First _____ Last: _____

Nickname: *(If relevant)* _____

DOB: __ __ / __ __ / __ __ __ __

Gender: Male Female

Name of Prior Interview Respondent (Primary Respondent)

Primary Respondent Contact Information

Name: _____

Relationship to patient: _____

Mailing address: _____

NICHD SUPPORT Trial
Pulmonary Outcomes Follow up Study

NICU Discharge-Baseline Interview

This interview should be administered by a trained study nurse to the parent/guardian. The target window for this interview is prior to NICU discharge or within the first 30 days following NICU discharge. For patients enrolled in the Pulmonary Outcomes Follow up Study after this target window, this interview should be performed at the time of enrollment.

This interview is for:

_____
(Child's name)

All questions pertain only to his/her health.

N.B. Parents or guardians expressing concerns regarding their child's breathing should be advised to discuss them with the family's primary care physician.

Introduction to the Study:
Premature babies are more likely than full term babies to have breathing problems after discharge from the NICU. The purpose of this study is to see whether or not the treatment your baby received as part of the SUPPORT Study improves your baby's breathing in the 18-22 months following the baby's due date.

As part of this study, we will contact you every 6 months or so to ask you questions about your baby's breathing. The questions will be about your baby's breathing symptoms, especially wheezing and coughing, and about your baby's need for medical visits and treatments for breathing problems.

Wheezing can mean different sounds to different people. By wheezing we mean an expiratory sound (a sound that is made when breathing out, not in) that comes from the chest, sometimes described as whistling or musical.

We have prepared a diary for you to help you keep track of your baby's breathing, especially breathing problems and treatments.

Give diary

To complete the diary, please record how often your baby has wheezing or coughing, whether your baby visited a doctor's office, emergency room or was hospitalized for breathing problems and what medications your baby needs. When we call, we'd like you to gather the diary and any medications or other information about your baby's breathing.

In order to help us understand your baby's breathing and risk for breathing problems at home, we'd like to ask you a few questions about your home and about whether breathing problems run in the family. As with all information we collect, the answers to these questions will be kept confidential.

NICU Discharge-Baseline Interview

Center: ___ Site: ___ Network No. ____ SUPPORT Follow-up No. _____ Birth No. ___ Mother's Initials: ___

1. Child's Name_____ _____ (first) (last) 2.Today's Date: |__|__| - |__|__| - |__|__|__|__| mm dd yyyy

3. Child's Sex: 1~ Male 2~ Female

4. Child's Birthdate: |__|__| - |__|__| - |__|__|__|__| mm dd yyyy

Enter name and relationship code of the person being interviewed.

5a. Name: _____ _____ 5b. Relationship Code: |__|__|__|

001 - Mother of Child
002 - Father of Child
301 - Adoptive mother
302 - Adoptive father

Other: _____
Common codes are listed here. For other relationships, please look up relationship code from Appendix B of the Follow up Manual of Procedures and enter above.

6. Type of Interview: 1~ Face to Face 2~ Telephone

At this time, we would like a little information about the environment in which your new child will grow up.

7. First, how many people normally live with you in your home for at least 6 months of the year?

Total household members: |__|__|

8. After the first few months, will your child be sharing a room with other family members on a regular basis?

1~ Yes 2~ No

8a. IF YES: How many people will sleep in the same room with him/her? |__|__|

9. How many rooms are there in your house, excluding closets and bathrooms? |__|__|

10. Do you have any pets inside the home? 1~ Yes 2~ No *Skip to Question 11*

If YES, how many.....
10a. *check and record number:* 1~ Dogs in the home? |__|__|
2~ Cats in the home? |__|__|
3~ Other pets are in the home? |__|__| SPECIFY: _____

11. Does your home or apartment have air conditioning or some kind of cooling? 1~ Yes 2~ No *Skip to Question 12*

If Yes, 11a. Air Conditioning? 1~ Yes 2~ No
11b. Evaporative Cooling? *(Desert Southwest)* 1~ Yes 2~ No
11c. Other? 1~ Yes 2~ No If YES, SPECIFY_____

12. How is your home heated? (IF MORE THAN ONE, PLEASE CHECK ALL THAT APPLY).
    - 1~ Steam or hot water (radiator)
    - 2~ Central gas furnace (furnace)
    - 3~ Electric
    - 4~ Wood Stove
    - 5~ Other SPECIFY: _____
    - 6~ Don't know

13. What one fuel is used most for cooking in your home?
    - 1~ Electricity
    - 2~ Gas
    - 3~ Fuel Oil
    - 4~ Wood Stove
    - 5~ Other SPECIFY: _____
    - 6~ Don't Know

The next questions are about your baby's diet.

14. Is your child receiving: (READ ALL CHOICES)
    - 1~ Only breast milk
    - 2~ Only formula *Skip to Question 15*
    - 3~ Both breast milk and formula *Skip to Question 15*

If answer to 14 is 1 (only breast milk)

a. Will this be supplemented with formula in the first 6 months?

1~ Yes 2~ No 2~ Don't Know

b. If yes, when will supplements begin? |___|___| months

15. Does the mother (you) plan to work outside the home within the next year?
    - 1~ Yes
    - 2~ No
    - 3~ Don't Know

The next questions are about smoke exposure.

16. Which one of the following 3 statements best describes the situation regarding smoking in your child's **home**? *Read all options to the interviewee before recording a response.*

    1❑ Smoking is allowed in any common room of the home
    2❑ Smoking is limited to part of the house where the child rarely goes
    3❑ There is no smoking inside at all → 16a. Are there any exceptions to this situation?

    1~ Yes 2~ No (Skip to Question 17)

    16b. Under what circumstances are the exceptions allowed? SPECIFY:

    _____

17. Which one of the following 5 statements best describes the situation regarding smoking in your **car**? *Read all options to the interviewee before recording a response.*
    1❑ Do not have a car
    2❑ Smoking is usually or always allowed
    3❑ Smoking is sometimes allowed
    4❑ Smoking occurs in the car only when the child is not inside
    5❑ There is no smoking inside the car → 17a. Are there any exceptions to this situation?

1~ Yes 2~ No (Skip to Question 18)

17b. Under what circumstances are the exceptions allowed? SPECIFY:

_____

18. How often has the baby's mother or primary caretaker (you) smoked since your child was born?

1~ Never 2~ Occasionally 3~ Daily

19. Altogether, how many people who live in the child's home smoke? |___|___| people

In the next section, we'd like to know what breathing and allergy problems run in the family. Administer attached Family History Questionnaire using the following script:

Mother or guardian:

We'll start with the baby's mother. How old is the baby's biologic mother? Does she have bronchitis, emphysema, COPD, bronchiectasis, asthma, inhaled allergies, or food allergies?

Does the baby's mother have any other chronic respiratory illness?

How often does this person smoke in the baby's home?

Father
For the baby's biologic father, is he living? How old is he? Does she have bronchitis, emphysema, COPD, bronchiectasis, asthma, inhaled allergies, or food allergies?

Does he have any other chronic respiratory illness?

How often does he smoke in the baby's home?

Complete the remainder of the table by collecting the same medical history using the scripting above.

20. Finally, which friend or relative is most likely to be able to contact you 6 months from now in case we lose contact with you?

Thank you for your help in providing us with this important information, and for your continued participation in the Pulmonary Follow up Study.

NICHD SUPPORT Trial
Pulmonary Outcomes Follow up Study

Administered At 6 And 12 Months Corrected Age

This interview should be administered by a trained study interviewer for:

_____
(Child's name)

All questions pertain only to his/her health.

The parent or care giver, who completed the initial interview, should complete this survey and all future surveys. The interviewer will need to ask for that parent (see Manual of Operations).

Introduction Script:
When parent or primary care giver is on phone:

Hello, my name is <your name>. I am calling from the <NICHD Center>. As you probably remember, when you were in the NICU you enrolled in our study about respiratory health of premature infants. I am calling to ask you some questions about your baby's breathing. It will take about 10-20 minutes to complete. Is this a good time for you?

As with all information we collect, the answers to these questions will be kept confidential.

Before we begin this interview, it would be helpful if you could gather your breathing diary and any medications your child has been prescribed or has been taking and have them in front of you.

1. TODAY'S DATE: |__|__| - |__|__| - |__|__|__|__|
mm dd yyyy

PLEASE CONFIRM PERSONAL INFORMATION AND MAKE NECESSARY CORRECTIONS.

Child's Name:_____ _____
(first) (last)

Enter name and relationship code of the person being interviewed:

2a. Name: _____ _____ 2b. Relationship Code: |__|__|__|

001 - Mother of Child
002 - Father of Child
301 - Adoptive mother
302 - Adoptive father

Other: _____
Common codes are listed here for other relationships, please look up relationship code from Appendix B of the Follow up Manual of Procedures and enter above.

3. Type of Interview: 1~ Face to Face 2~ Telephone

4. Location of Interviewer: 1~ Local Center (Option 1) 2~ Rochester (Option 2)

Instructions:
Parents or guardians expressing concerns regarding their child's breathing should be advised to discuss them with the family's primary care physician.

Where the phrase "last contact" is used below, please substitute with the most specific relevant time prompt, e.g. for the 6 month interview, refer to "since NICU discharge"; for the 12 month interview, refer to "over the past 6 months", etc.

Interview begins:
Some of these questions will be familiar to you. Since we last spoke (__ __) months ago on (__ __/__ __/__ __) we want to learn what changes, if any, there have been to your child's health. We are especially interested in any breathing problems your child may have.

5. Has the child been with you during the past 6 months? 1~ Yes 2~ No

Since our last contact with you about your child.....

6. How many times has your child visited a doctor's office? |___|___| times

6a. How many of these times were because of wheezing or breathing problems? |___|___| times

Since our last contact with you about your child.....

7. How many times has your child visited an Emergency Department (Emergency room)? |___|___| times

7a. How many of these times were because of wheezing or breathing problems? |___|___| times

Since our last contact with you about your child.....

8. How many times has your child stayed in the hospital for one or more nights in a row? |___|___| times

8a. How many of these times were because of wheezing or breathing problems? |___|___| times

The next questions are about your baby's breathing.
The first question is about wheezing. By wheezing we mean an expiratory sound (a sound that is made when breathing out, not in) that comes from the chest, sometimes described as whistling or musical.

9. Since our last contact with you, has your baby's chest sounded wheezy or whistling?

1~ Yes 2~ No 3~ Don't know

Question 9a. "Has your baby's breathing sounded like this?" ***(play audio clip of wheezing).***

1~ Yes 2~ No 3~ Don't know If 2 or 3, SKIP TO QUESTION 10

IF **YES** TO QUESTION 9 or 9a:

9b. Has this occurred with colds?

1~ Yes
2~ No *Skip to c*
3~ Sometimes

9c. Has your child's chest sounded wheezy or whistling apart from colds?

1~ Yes
2~ No

9d. During what month did your child's chest first sound wheezy or whistling?

|___|___|months (enter calendar month, Jan = 01; Feb = 02); |___|___| Year

9e. Over the past 6 months, **on average**, how often has your child's chest sounded wheezy or whistling during:

The Daytime? Would you say...(e.1)

1❑ Never
2❑ Twice a week
3❑ More than two times a week, but not every day
4❑ Everyday, but *not* all the time
5❑ Everyday, all the time

The Nighttime? Would you say...(e.2)

1❑ Never
2❑ Once every two weeks or less
3❑ Once a week
4❑ More than 1 night a week
5❑ Frequently/Every night

9f. Over the past 6 months, **during the worst 2 week period**, how often has your child's chest sounded wheezy or whistling during:

The Daytime? Would you say... (f.1)

1❑ Never
2❑ Twice a week
3❑ More than two times a week, but not every day
4❑ Everyday, but *not* all the time
5❑ Everyday, all the time

The Nighttime? Would you say...(f.2)

1❑ Never
2❑ Once every two weeks or less
3❑ Once a week
4❑ More than 1 night a week
5❑ Frequently/Every night

9g. Since our last contact with you, has your child taken any medicine prescribed by a doctor for wheezing?

1~ Yes
2~ No

IF YES, BE SURE TO COMPLETE QUESTION 27

10. Since our last contact with you, has your child had a cough when he/she did not have a cold?

1~ Yes 2~ No SKIP TO QUESTION 11

IF **YES** TO QUESTION 10

10a. At what time of the day has this cough usually occurred?
(CHECK ALL THAT APPLY)

1~ In the morning, shortly after rising
2~ Later in the day
3~ During the night
4~ No relation to time of day

10b. Has he/she coughed on most days for as much as 2 to 3 months?

1~ Yes
2~ No

10c. During what month and year did your child first develop the cough?

|___|___|months (enter calendar month, Jan = 01; Feb = 02); |___|___| Year

10d. Has your child's chest ever sounded wheezy or whistling with episodes of coughing?

1~ Yes
2~ No

10e. Over the past 6 months, **on average**, how often has your child had coughing during:

The Daytime? Would you say... (e.1)	***The Nighttime? Would you say...(e.2)***
1❑ Never	1❑ Never
2❑ Twice a week	2❑ Once every two weeks or less
3❑ More than two times a week, but not every day	3❑ Once a week
4❑ Everyday, but *not* all the time	4❑ More than 1 night a week
5❑ Everyday, all the time	5❑ Frequently/Every night

10f. Over the past 6 months, **during the worst 2-week period**, how often has your child had coughing?

The Daytime? Would you say... (f.1)	***The Nighttime? Would you say...(f.2)***
1❑ Never	1❑ Never
2❑ Twice a week	2❑ Once every two weeks or less
3❑ More than two times a week, but not every day	3❑ Once a week
4❑ Everyday, but *not* all the time	4❑ More than 1 night a week
5❑ Everyday, all the time	5❑ Frequently/Every night

11. Over the past 6 months, **on average**, how many **days per month** did you have to change your daytime or evening plans because of your child's breathing problems: |___|___| # of days

12. Over the past 6 months, **during the worst 2 week period**, how many **days** did you have to change for daytime or evening plans because of your child's breathing problems: |___|___| # of days

13. Since our last contact with you, has your child had asthma or reactive airways disease diagnosed by a doctor?
1~ Yes 2~ No

14. Since our last contact with you, has your child had bronchiolitis, bronchitis, or pneumonia diagnosed by a doctor?
1~ Yes 2~ No

15. Since our last contact with you, has your child had croup diagnosed by a doctor?
1~ Yes 2~ No

The next questions are about your baby's diet.

16. In the past 6 months, did your baby receive mother's breast milk, either at breast, from a bottle or through a tube?

1~ Yes 2~ No If NO, skip to Question 17

If yes to Question 16:

16a. For how many months did your child receive breast milk feedings?
Would you say... 1~ Less than 1 month
2~ 1-3 months
3~ 4-6 months

16b. For how many months did your child receive breast milk for more than half of his/her feedings?
Would you say... 1~ Less than 1 month
2~ 1-3 months
3~ 4-6 months

The next questions are about smoke exposure.

17. Which one of the following 3 statements best describes the situation regarding smoking in your child's **home**? *Read all options to the interviewee before recording a response.*
1❑ Smoking is allowed in any common room of the home
2❑ Smoking is limited to part of the house where the child rarely goes
3❑ There is no smoking inside at all → 17a. Are there any exceptions to this situation?

1~ Yes 2~ No (Skip to Question 18)

17b. Under what circumstances are the exceptions allowed? SPECIFY:

_____

18. Which one of the following 5 statements best describe the situation regarding smoking in your **car**? *Read all options to the interviewee before recording a response.*
1❑ Do not have a car
2❑ Smoking is usually or always allowed
3❑ Smoking is sometimes allowed
4❑ Smoking occurs in the car only when the child is not inside
5❑ There is no smoking inside the car → 18a. Are there any exceptions to this situation?

1~ Yes 2~ No (Skip to Question 19)

18b. Under what circumstances are the exceptions allowed? SPECIFY:

_____

19. How often has the **mother or primary care giver** smoked since your child was born?

1~ Never 2~ Occasionally 3~ Daily

20. How many people in the child's home smoke? |___|___| people

The next questions are about your home and your babysitter's home or day care.

21. Approximately how many hours per week does your child spend at a babysitter's home or day care?
|___|___| hrs *If 0, skip to Question 22*

___IF 21 is greater than 0:

21a. How frequent is there smoke exposure at the babysitter or daycare?

1~ Never 2~ Occasionally 3~ Daily 4~ Don't Know

21b. How many children beside your baby are in the daycare? |___|___|___| children

22. How many children under 12 live in your house? |___|___| children

23. Do you have any pets inside the home? 1~ Yes 2~ No *Skip to Question 24*

23a. If YES, how many pets are there inside the home?
Check all that apply and record number: 1~ Dogs |___|___|
2~ Cats |___|___|
3~ Other |___|___| SPECIFY: _____

The last questions involve respiratory treatments that your baby may receive.

PROPHYLAXIS

24. Has your child had RSV shots to prevent Respiratory Syncytial Virus (Synagis, palivizumab, RSV shot)?

1~ Yes 2~ No 3~ Don't know

25. Has your child had a flu shot? 1~ Yes 2~ No 3~ Don't know

OXYGEN

26. Is your child on any oxygen therapy at home?

1~ Yes 2~ No Skip to Question 27

Indicate Yes or No for each			*lpm = liters per minute
26a. Oxygen cannula	1~ Yes	2~ No FiO2_____	lpm*_____
26b. Oxygen hood	1~ Yes	2~ No FiO2_____	lpm*_____
26c. Ventilator	1~ Yes	2~ No FiO2_____	lpm*_____

MEDICATIONS *(Enter responses in table. Do not prompt for each medication in the Medication Code List below.)*

The last two questions involve the medicines your child is taking for breathing problems.

27. What medicines is your baby taking, including medicines delivered by a nebulizer or breathing machine at home?	27a. Code	27b. Does he/she take that medicine everyday, sometimes or only when sick? *(repeat for each medication)*
1		1❑ Everyday 2❑ Sometimes 3❑ Only when Sick
2		1❑ Everyday 2❑ Sometimes 3❑ Only when Sick
3		1❑ Everyday 2❑ Sometimes 3❑ Only when Sick
4		1❑ Everyday 2❑ Sometimes 3❑ Only when Sick
5		1❑ Everyday 2❑ Sometimes 3❑ Only when Sick
6		1❑ Everyday 2❑ Sometimes 3❑ Only when Sick
7		1❑ Everyday 2❑ Sometimes 3❑ Only when Sick

Medication Code List:

Rescue medicines:
1 Albuterol
2 Proventil
3 Serevent
4 Ventolin
5 Volmax
6 Xopenex

Inhaled medications:
7 Cromolyn (Intal)
8 Nedocromil (Tilade)

Inhaled steroids:
9 Advair
10 Aerobid
11 Azmacort
12 Beclovent
13 Flovent
14 Vanceril
15 Pulmicort

Systemic steroids:
16 Decadron
17 Prednisone

Leukotriene blocker:
18 Accolate
19 Singulair

Methylxanthines:
20 Theophylline

Diuretic medications:
21 Diuril
22 Lasix
23 Aldactizide
24 Aldactone

Miscellaneous / Non-specific
25 Nebulizer
26 Other_____

Thank you for your cooperation in providing us with this important information, and for your continued participation in the Pulmonary Follow Up Study. Please continue to keep your baby's breathing diary up to date.

NICHD SUPPORT Trial
Pulmonary Outcomes Follow up Study

Administered At 18-22 Months Corrected Age

This interview should be administered by a trained study interviewer. The target window for this interview is between 8-22 months' corrected age.

_____
(Child's name)

All questions pertain only to his/her health.

Introduction Script:
When parent or primary care giver is on phone:

Hello, my name is <your name>. I am calling from the <NICHD Center>. As you probably remember, when you were in the NICU you enrolled in our study about respiratory health of premature infants. I am calling to ask you some questions about your baby's breathing. It will take about 10-20 minutes to complete. Is this a good time for you?

As with all information we collect, the answers to these questions will be kept confidential.

Before we begin this interview, it would be helpful if you could gather your breathing diary and any medications your child has been prescribed or has been taking and have them in front of you.

1. TODAY'S DATE: |__|__| - |__|__| - |__|__|__|__|
mm dd yyyy

PLEASE CONFIRM PERSONAL INFORMATION AND MAKE NECESSARY CORRECTIONS.

Child's Name:_____ _____

Enter name and relationship code of the person being interviewed*:

2a. Name: _____ _____ 2b. Relationship Code: |__|__|__|

001 - Mother of Child
002 - Father of Child
301 - Adoptive mother
302 - Adoptive father

Other: _____
Common codes are listed here for other relationships, please look up relationship code from Appendix B of the Follow up Manual of Procedures and enter above.

3. Type of Interview: 1~ Face to Face 2~ Telephone

4. Location of Interviewer: 1~ Local Center (Option 1) 2~ Rochester (Option 2)

Instructions:
Parents or guardians expressing concerns regarding their child's breathing should be advised to discuss them with the family's primary care physician.

Where the phrase "last contact" is used below, please substitute with the most specific relevant time prompt, e.g. for the 18-22 month interview, refer to "over the past 6 months", etc.

Interview begins:
Some of these questions will be familiar to you. Since we last spoke (__ __) months ago on (__ __/__ __/__ __) we want to learn what changes, if any, there have been to your child's health. We are especially interested in any breathing problems your child may have.

5. Has the child been with you over the past 6 months? 1~ Yes 2~ No

Since our last contact with you about your child...

6. How many times has your child visited a doctor's office? |__|__| times

6a. How many of these times were because of wheezing or breathing problems? |__|__| times

Since our last contact with you about your child...

7. How many times has your child visited an Emergency Department (Emergency room)? |__|__| times

7a. How many of these times were because of wheezing or breathing problems? |__|__| times

Since our last contact with you about your child...

8. How many times has your child stayed in the hospital one or more nights in a row? |__|__| times

8a. How many of these times were because of wheezing or breathing problems? |__|__| times

The next questions are about your baby's breathing.

The first question is about wheezing. By wheezing we mean an expiratory sound (a sound that is made when breathing out, not in) that comes from the chest, sometimes described as whistling or musical. It can sound like this,..... (play audio clip of wheezing).

9. Since our last contact with you, has your baby's chest sounded wheezy or whistling?

1~ Yes 2~ No 3~ Don't know If 2 or 3, SKIP TO QUESTION 10

Question 9a. "Has your baby's breathing sounded like this?" ***(play audio clip of wheezing).***

1~ Yes 2~ No 3~ Don't know If 2 or 3, SKIP TO QUESTION 10

IF **YES** TO QUESTION 9 or 9a:

9b. Has this occurred with colds?

1~ Yes
2~ No *Skip to c*
3~ Sometimes

9c. Has your child's chest sounded wheezy or whistling apart from colds?

1~ Yes
2~ No

9d. During what month and year did your child's chest first sound wheezy or whistling?

|___|___|months (enter calendar month, Jan = 01; Feb = 02); |___|___| Year

9e. Over the past 6 months, **on average**, how often has your child's chest sounded wheezy or whistling during:

The Daytime? Would you say...(e.1)	***The Nighttime? Would you say...(e.2)***
1❑ Never	1❑ Never
2❑ Twice a week	2❑ Once every two weeks or less
3❑ More than two times a week, but not every day	3❑ Once a week
4❑ Everyday, but *not* all the time	4❑ More than 1 night a week
5❑ Everyday, all the time	5❑ Frequently/Every night

9f. Over the past 6 months, **during the worst 2 week period**, how often has your child's chest sounded wheezy or whistling during:

The Daytime? Would you say... (f.1)	***The Nighttime? Would you say...(f.2)***
1❑ Never	1❑ Never
2❑ Twice a week	2❑ Once every two weeks or less
3❑ More than two times a week, but not every day	3❑ Once a week
4❑ Everyday, but *not* all the time	4❑ More than 1 night a week
5❑ Everyday, all the time	5❑ Frequently/Every night

9g. Since our last contact with you, has your child taken any medicine prescribed by a doctor for wheezing?

1~ Yes
2~ No

10. Since our last contact with you, has your child had a cough when he/she did not have a cold?

1~ Yes 2~ No SKIP TO QUESTION 11

IF **YES** TO QUESTION 10

10a. At what time of the day has this cough usually occurred?
(CHECK ALL THAT APPLY)

1~ In the morning, shortly after rising
2~ Later in the day
3~ During the night
4~ No relation to time of day

10b. Has he/she coughed on most days for as much as 2 to 3 months?

1~ Yes
2~ No

10c. During what month and year did your child first develop the cough?

|___|___|months (enter calendar month, Jan = 01; Feb = 02); |___|___| Year

10d. Has your child's chest ever sounded wheezy or whistling with episodes of coughing?

1~ Yes
2~ No

10e. Over the past 6 months, **on average**, how often has your child had coughing during:

The Daytime? Would you say... (e.1)	***The Nighttime? Would you say...(e.2)***
1❑ Never	1❑ Never
2❑ Twice a week	2❑ Once every two weeks or less
3❑ More than two times a week, but not every day	3❑ Once a week
4❑ Everyday, but *not* all the time	4❑ More than 1 night a week
5❑ Everyday, all the time	5❑ Frequently/Every night

10f. Over the past 6 months, **during the worst 2-week period**, how often has your child had coughing?

The Daytime? Would you say... (f.1)	***The Nighttime? Would you say...(f.2)***
1❑ Never	1❑ Never
2❑ Twice a week	2❑ Once every two weeks or less
3❑ More than two times a week, but not every day	3❑ Once a week
4❑ Everyday, but *not* all the time	4❑ More than 1 night a week
5❑ Everyday, all the time	5❑ Frequently/Every night

11. Over the past 6 months, **on average**, how many **days per month** did you have to change your daytime or evening plans because of your child's breathing: |___|___| # of days

12. Over the past 6 months, **during the worst 2 week period**, how many **days** did you have to change for daytime or evening plans because of your child's breathing: |___|___| # of days

13. Since our last contact with you, has your child had asthma or reactive airways disease diagnosed by a doctor?
1~ Yes 2~ No

14. Since our last contact with you, has your child had bronchiolitis, bronchitis, or pneumonia diagnosed by a doctor?
1~ Yes 2~ No

15. Since our last contact with you, has your child had croup diagnosed by a doctor?
1~ Yes 2~ No

The next question are about your baby's diet.

16. In the past 6 months, did your baby receive mother's breast milk, either at breast, from a bottle or through a tube?

1~ Yes 2~ No If NO, skip to Question 17

If yes to Question 16:

16a. For how many months did your child receive breast milk feedings?
Would you say... 1~ Less than 1 month
2~ 1-3 months
3~ 4-6 months

16b. For how many months did your child receive breast milk for more than half of his/her feedings?
Would you say... 1~ Less than 1 month
2~ 1-3 months
3~ 4-6 months

The next questions are about smoke exposure.

17. Which one of the following 3 statements best describes the situation regarding smoking in your child's **home**? *Read all options to the interviewee before recording a response.*
1❑ Smoking is allowed in any common room of the home
2❑ Smoking is limited to part of the house where the child rarely goes
3❑ There is no smoking inside at all → 17a. Are there any exceptions to this situation?

1~ Yes 2~ No (Skip to Question 18)

17b. Under what circumstances are the exceptions allowed? SPECIFY:

_____

18. Which one of the following 5 statements best describes the situation regarding smoking in your **car**? *Read all options to the interviewee before recording a response.*
1❑ Do not have a car
2❑ Smoking is usually or always allowed
3❑ Smoking is sometimes allowed
4❑ Smoking occurs in the car only when the child is not inside
5❑ There is no smoking inside the car → 18a. Are there any exceptions to this situation?

1~ Yes 2~ No (Skip to Question 19)

18b. Under what circumstances are the exceptions allowed? SPECIFY:

_____

19. How often has the **mother or primary care giver** smoked since your child was born?

1~ Never 2~ Occasionally 3~ Daily

20. How many people in the child's home smoke? |___|___| people

The next questions are about your home and your babysitter's home or day care.

21. Approximately how many hours per week does your child spend at a babysitter's home or day care?
|___|___| hrs If 0 skip to question 22.

IF 21 is greater than 0:

21a. How frequent is there smoke exposure at the babysitter or daycare?

1~ Never 2~ Occasionally 3~ Daily 4~ Don't Know

21b. How many children beside your baby are in the daycare? |___|___|___| children

22. How many children under 12 live in your house? |___|___| children

23. Do you have any pets inside the home? 1~ Yes 2~ No Skip to Question 24

23a. If YES, how many pets are there inside the home?
Check all that apply and record number: 1~ Dogs |___|___|
2~ Cats |___|___|
3~ Other |___|___| SPECIFY: _____

The last questions involve respiratory treatments that your baby may receive.

PROPHYLAXIS

24. Has your child had RSV shots to prevent Respiratory Syncytial Virus (Synagis, palivizumab RSV, shot)?

1~ Yes 2~ No 3~ Don't know

25. Has your child had a flu shot? 1~ Yes 2~ No 3~ Don't know

OXYGEN

26. Is your child on any oxygen therapy (oxygen tank) at home?

1~ Yes 2~ No Skip to Question 27

Indicate Yes or No for each				*lpm = liters per minute
a. Oxygen cannula	1~ Yes	2~ No	FiO2_____	lpm*_____
b. Oxygen hood	1~ Yes	2~ No	FiO2_____	lpm*_____
c. Ventilator	1~ Yes	2~ No	FiO2_____	lpm*_____

MEDICATIONS *(Enter responses in table. Do not prompt for each medication in the Medication Code List below.)*

The last two questions involve the medicines your child is taking for breathing problems.

25 Nebulizer
26 Other_____

The last questions regard allergies.

28. **During the past year**, for how many days has your child been unable to do his/her usual activities because of illnesses such as chest (not head) colds, bronchitis, asthma or pneumonia?
1❑ 0-3 per year
2❑ 4-5 per year
3❑ 6-9 per year
4❑ more than 9 per year

29. How many head colds (common colds) **per year** does your child usually have? Would you say...
1❑ 0-3 per year
2❑ 4-5 per year
3❑ 6-9 per year
4❑ more than 9 per year

30. Has your child **ever** had hay fever or any other condition that makes his/her nose runny, stuffy, or itchy **apart** from colds? 1~ Yes 2~ No

31. Has your child **ever** had allergies which cause nose, eye or lung problems?
1~ Yes 2~ No

32. Has your child **ever** been allergic to any food?
1~ Yes 2~ No

33. Has he/she **ever** been allergic to any medicine?
1~ Yes 2~ No

34. Has your child **ever** had eczema (allergic skin rash)?
1~ Yes 2~ No (End of Interview)

34a. Was eczema diagnosed by a doctor?

QUESTION

1~ Yes 2~ No

End of Interview THANK YOU FOR YOUR COOPERATION

Attachments: SUPP_GRO 01 form.doc

Hi Rose,

Please take a look at the data collection form that Cristina came up with. She took the Glutamine data collection form that many of the coordinators are already familiar with and modified it so that the anthropometric data and nutrrition data are on the same sheet. Much of the anthropometric data are already collected for GDB at some of the listed time points, but I recall from our last meeting that the coordinators preferred to have all data for a particular study on the same sheet. Ruth helped us with the sheet and thought it should meet coordinator needs - 1 sheet per baby per day of data collection.

Hope it looks OK to you. What do we do next - does she need a working group? If she does, I would suggest Richard, Brenda, Seetha (who has expressed an interest in the IUGR sub-group) and Neil. Also, when do we need the Manual of Operations by? The Savannah meeting? Ruth pulled out our premie board - its not bad ... a fairly light plexiglass gizmo about 6 inches wide and 24 inches long which she will bring to GA for the demo.

We are very excited to be starting and hope some good information comes out of the effort

Shahnaz

Hi Tina,

Not bad - could you knock off the highlighted sections at the bottom? I don't think route or supplements are critical and will only annoy people if we collect data unlikely to be used.

Subject: SAE-Support

Attached is a support MedWatch. The one on line can be filled out. Is it OK to use it if I identify the study in the Patient Identifier section?

The FDA Safety Information and Adverse Event Reporting Program

For VOLUNTARY reporting of adverse events and product problems

FDA USE ONLY

Triage unit sequence #

A. PATIENT INFORMATION

1. Patient Identifier	2. Age at Time of Event: / Date of Birth:	3. Sex	4. Weight
(b) (6) SUPPORT Trial In confidence	1 Days / or / (b) (6)	☐ Female ☒ Male	____ lbs or 0.890 kgs

B. ADVERSE EVENT OR PRODUCT PROBLEM

1. ☒ **Adverse Event** and/or ☐ **Product Problem** *(e.g., defects/malfunctions)*

2. **Outcomes Attributed to Adverse Event** *(Check all that apply)*
- ☒ Death (b) (6) *(mo/day/yr)*
- ☐ Life-threatening
- ☐ Hospitalization - initial or prolonged
- ☐ Disability
- ☐ Congenital Anomaly
- ☐ Required Intervention to Prevent Permanent Impairment/Damage
- ☐ Other: _____

3. **Date of Event** *(mo/day/year)*: (b) (6)

4. **Date of This Report** *(mo/day/year)*: (b) (6)

5. **Describe Event or Problem**

27 +2 week infant twin. 890 grams BW. Required bag/mask ventilation in the delivery room, but was stabalized and transported to NICU on CPAP. Maintained on CPAP for approx. 15 hours. At that time the infant was intubated for increased FiO2 and CO2 in the 70's. At the time of the intubation breath sounds were noted to be decreased on the right side. An X-Ray confirmed a R pneumothorax, which was aspirated with a butterfly needle. CO2 and oxygen saturation slowly improved. At approx. 19 hours of age the infant started to deteriorate with increasing FiO2 levels and CO2. Blood gas values were pH 7.02 CO2 98 PO2 58 Base Excess -8, and FiO2 77 on high frequency ventilation. Transillumination of the chest showed a reaccumulated pneumothorax, and a Chest Tube was placed. Copious amounts of blood were seen to be coming from the chest tube. CT surgery was called but did not arrive in time. The infant was given atropine and epinepherine. At 04:35 the infant died.

6. **Relevant Tests/Laboratory Data, Including Dates**

7. **Other Relevant History, Including Preexisting Medical Conditions** *(e.g., allergies, race, pregnancy, smoking and alcohol use, hepatic/renal dysfunction, etc.)*

C. SUSPECT MEDICATION(S)

1. **Name** *(Give labeled strength & mfr/labeler, if known)*
#1
#2

2. Dose, Frequency & Route Used	3. Therapy Dates *(If unknown, give duration)* from/to (or best estimate)
#1	#1
#2	#2

4. **Diagnosis for Use** *(Indication)*
#1
#2

5. **Event Abated After Use Stopped or Dose Reduced?**
#1 ☐ Yes ☐ No ☐ Doesn't Apply
#2 ☐ Yes ☐ No ☐ Doesn't Apply

6. Lot # *(if known)*	7. Exp. Date *(if known)*
#1	#1
#2	#2

8. **Event Reappeared After Reintroduction?**
#1 ☐ Yes ☐ No ☐ Doesn't Apply
#2 ☐ Yes ☐ No ☐ Doesn't Apply

9. **NDC#** *(For product problems only)*
- -

10. **Concomitant Medical Products and Therapy Dates** *(Exclude treatment of event)*

D. SUSPECT MEDICAL DEVICE

1. **Brand Name**

2. **Type of Device**

3. **Manufacturer Name, City and State**

4. Model #	Lot #	5. Operator of Device
Catalog #	Expiration Date *(mo/day/yr)*	☐ Health Professional ☐ Lay User/Patient ☐ Other:
Serial #	Other #	

6. **If Implanted, Give Date** *(mo/day/yr)*

7. **If Explanted, Give Date** *(mo/day/yr)*

8. **Is this a Single-use Device that was Reprocessed and Reused on a Patient?** ☐ Yes ☐ No

9. **If Yes to Item No. 8, Enter Name and Address of Reprocessor**

10. **Device Available for Evaluation?** *(Do not send to FDA)* ☐ Yes ☐ No ☐ Returned to Manufacturer on: _____ *(mo/day/yr)*

11. **Concomitant Medical Products and Therapy Dates** *(Exclude treatment of event)*

E. REPORTER *(See confidentiality section on back)*

1. Name and Address	Phone #

The FDA Safety Information and Adverse Event Reporting Program

For VOLUNTARY reporting of adverse events and product problems

5. **Describe Event or Problem** *(continued)*

6. **Relevant Tests/Laboratory Data, Including Dates** *(continued)*

7. **Other Relevant History, Including Preexisting Medical Conditions** *(e.g., allergies, race, pregnancy, smoking and alcohol use, hepatic/renal dysfunction, etc.) (continued)*

Concomitant Medical Products and Therapy Dates *(Exclude treatment of event) (continued)*

ADVICE ABOUT VOLUNTARY REPORTING

Report adverse experiences with:

- Medications *(drugs or biologics)*
- Medical devices *(including in-vitro diagnostics)*
- Special nutritional products *(dietary supplements, medical foods, infant formulas)*
- Cosmetics
- Medication errors

Report product problems - quality, performance or safety concerns such as:

- Suspected counterfeit product
- Suspected contamination
- Questionable stability
- Defective components
- Poor packaging or labeling
- Therapeutic failures

Report SERIOUS adverse events. An event is serious when the patient outcome is:

- Death
- Life-threatening *(real risk of dying)*
- Hospitalization *(initial or prolonged)*
- Disability *(significant, persistent or permanent)*
- Congenital anomaly
- Required intervention to prevent permanent impairment or damage

Report even if:

- You're not certain the product caused the event
- You don't have all the details

How to report:

- Just fill in the sections that apply to your report
- Use section C for all products except medical devices
- Attach additional blank pages if needed
- Use a separate form for each patient
- Report either to FDA or the manufacturer *(or both)*

Confidentiality: The patient's identity is held in strict confidence by FDA and protected to the fullest extent of the law. FDA will not disclose the reporter's identity in response to a request from the public, pursuant to the Freedom of Information Act. The reporter's identity, including the identity of a self-reporter, may be shared with the manufacturer unless requested otherwise.

If your report involves a serious adverse event with a device and it occurred in a facility outside a doctor's office, that facility may be legally required to report to FDA and/or the manufacturer. Please notify the person in that facility who would handle such reporting.

Important numbers:

- 1-800-FDA-0178 -- To FAX report
- 1-800-FDA-1088 -- To report by phone or for more information
- 1-800-822-7967 -- For a VAERS form for vaccines

To Report via the Internet:

http://www.fda.gov/medwatch/report.htm

The public reporting burden for this collection of information has been estimated to average 30 minutes per response, including the time for reviewing instructions, searching existing data sources, gathering and maintaining the data needed, and completing and reviewing the collection of information. Send comments regarding this burden estimate or any other aspect of this collection of information, including suggestions for reducing this burden to:

Rockville, MD 20852-9787

General Instructions for Completing the MedWatch Form FDA 3500

For use by health professionals and consumers for voluntary reporting of adverse events and product problems with medications (drugs or biologics, **except vaccines**), medical devices (including in vitro diagnostics), special nutritional products (dietary supplements, infant formulas, medical foods) and other FDA-regulated medical products. Events involving vaccines should be reported to the Vaccine Adverse Event Reporting System (VAERS) (http://www.fda.gov/cber/vaers/report.htm).

Note for consumers: If possible, please take the 3500 form to your health professional (e.g., doctor or pharmacist) so that information based on your medical record that can help in the evaluation of your report will be provided. If, for whatever reason, you do not wish to have your health professional fill out the form, you are welcome to do so yourself.

GENERAL INSTRUCTIONS

- Please make sure that all entries are either typed, printed in a font no smaller than 10 point, or written using black ink.
- Please complete all sections that apply to your report.
- To complete an item when information is not available, use the following as appropriate:
  - NA for not applicable
  - NI for no information at this time (but may become available later)
  - UNK for unknown
- Dates should be entered as month/day/year (e.g., June 3, 1998 = 06/03/1998).
  If exact dates are unknown, please provide the best estimate.
- For narrative entries, if the fields do not provide adequate space, attach an additional page(s) as needed.
- If the case report involves more than two (2) suspect medications or devices, please submit another copy of FDA Form 3500, with only **Section C** or **Section D** filled in as appropriate.
- **Section C** (Suspect medication(s)) may be used to report on special nutritional products such as dietary supplements as well as drugs or biologics.
- If your report involves a serious adverse event with a device and it occurred in a facility other than a doctor's office, that facility may be legally required to report to FDA and/or the manufacturer. Please notify the person in that facility who would handle such reporting.
- Please incorporate the following specific information:
  - Identify all attached pages as Page __ of __
  - Indicate the appropriate section and block number next to the narrative continuation
  - Include the phrase continued at the end of each field that has additional information continued onto another page

If you have further questions about completing this form, call MedWatch at: 1-800-FDA-1088.

SECTION A: PATIENT INFORMATION

Complete a separate form for each patient, unless the report involves a medical device where multiple patients were adversely affected through the use of the same device. In that case, please indicate the number of patients in block B5 (Describe event or problem) and complete Section A and blocks B2, B5, B6, B7, and D11 for each patient. Enter the corresponding patient identifier in block A1 for each patient involved in the event.

When a newborn baby is found to have a congenital anomaly that the initial reporter considers possibly associated with a product administered to the mother during pregnancy, the patient is the newborn baby.

Parent-child/fetus report(s) are those cases in which either a fetus/suckling infant or the mother, or both, sustain an adverse event that the initial reporter considers possibly associated with a product administered to the mother during pregnancy. Several general principles are used for filing these reports:

- If there has been no event affecting the child/fetus, report only on the parent. For those cases describing fetal demise or spontaneous abortion, only a parent report is applicable
- When only the child/fetus has an adverse reaction/event (other than spontaneous abortion/ fetal demise), the information provided in section A applies to the child/fetus, and characteristics concerning the parent who was the source of exposure to the product is to be provided in section C
- If both the parent and the child/fetus sustain adverse events, two reports should be provided and linked using the narrative
- For devices, one form can be used in this circumstance

A1: Patient identifier

Please provide the patient's initials or some other type of identifier that will allow you, the reporter, to readily locate the case if you are contacted for more information. **Do not use the patient's name or social security number**.

The patient's identity is held in strict confidence by FDA and protected to the fullest extent of the law.

If no patient was involved (such as may be the case with a product problem), enter none.

A2: Age at time of event or Date of birth

Provide the most precise information available. Enter the patient's birthdate, if known, or the patient's age at the time of event onset. For age, indicate time units used (e.g., years, months, days).

- If the patient is 3 years or older, use years (e.g., 4 years)
- If the patient is less than 3 years old, use months (e.g., 24 months)
- If the patient is less than 1 month old, use days (e.g., 5 days)
- Provide the best estimate if exact age is unknown

A3: Sex

Enter the patient's gender. If the adverse event is a congenital anomaly, report the sex of the child.

A4: Weight

Indicate whether the weight is in pounds (lbs) or kilograms (kgs). Make a best estimate if exact weight is unknown.

SECTION B: ADVERSE EVENT OR PRODUCT PROBLEM

B1: Adverse event *and/or* Product problem

Choose the appropriate box. Both boxes should be checked if a product problem may have caused or contributed to the adverse event.

Adverse event: Any incident where the use of a medication (drug or biologic), at any dose, a medical device (including *in vitro* diagnostics) or a special nutritional product (e.g., dietary supplement, infant formula or medical food) is suspected to have resulted in an adverse outcome in a patient.

To report, it is not necessary to be certain of a cause/effect relationship between the adverse event and the use of the medical product(s) in question. Suspicion of an association is sufficient reason to report. Submission of a report does not constitute an admission that medical personnel or the product caused or contributed to the event.

Please limit your submissions to those events that are serious. An event is classified as serious when the patient outcome is:

- Death
- Life-threatening
- Hospitalization (initial or prolonged)
- Disability
- Congenital anomaly
- Required medical or surgical intervention to prevent permanent impairment or damage

Please see instructions for block **B2** for further information on each of these criteria.

While voluntary MedWatch reporting with Form 3500 is designed for serious reports only, you are welcome to report even if your case does not meet any of these specific criteria and you feel strongly that FDA should review the report. In that situation, you should check the other box and specify the reason for reporting, including patient outcome, in the space provided. The actual narrative of the event should be entered in block **B5**.

Product problem (e.g., defects/malfunctions): Any report regarding the quality, performance, or safety of any medication, medical device or special nutritional product. In addition, please select this category when reporting device malfunctions that could lead to a death or serious injury if the malfunction were to recur.

Product problems include, but are not limited to, such concerns as:

- Suspected contamination
- Questionable stability
- Defective components
- Therapeutic failures
- Product confusion (caused by name, labeling, design or packaging)
- Suspected super potent or subpotent medication
- Labeling problems caused by printing errors/ omissions

B2: Outcomes attributed to adverse event: Indicate all that apply to the reported event:

Death: Check only if you suspect that the death was an outcome of the adverse event, and include the date if known.

Do not check if:

- The patient happened to die while using a medical product, but there was no suspected association between the death and the use of the product
- A fetus is aborted because of a congenital anomaly, or is miscarried

Life-threatening: Check if suspected that:

- The patient was at substantial risk of dying at the time of the adverse event

  or

- Use or continued use of the device or other medical product might have resulted in the death of the patient

Hospitalization (initial or prolonged): Check if admission to the hospital or prolongation of hospitalization was a result of the adverse event.

Do not check if:

- A patient in the hospital received a medical product and subsequently developed an otherwise nonserious adverse event, unless the adverse event prolonged the hospital stay

Do check if:

- A patient is admitted to the hospital for one or more days, even if released on the same day
- An emergency room visit results in admission to the hospital
- Emergency room visits that do not result in admission to the hospital should be evaluated for one of the other serious outcomes (e.g., life-threatening; required intervention to prevent permanent impairment or damage)

Disability: Check if the adverse event resulted in a substantial disruption of a person's ability to conduct normal life functions. Such would be the case if the adverse event resulted in a significant, persistent or permanent change, impairment, damage or disruption in the patient's body function/structure, physical activities and/or quality of life.

Congenital anomaly: Check if you suspect that exposure to a medical product prior to conception or during pregnancy may have resulted in an adverse outcome in the child.

Required intervention to prevent permanent impairment or damage: Check if you believe that medical or surgical intervention was necessary to preclude permanent impairment of a body function, or prevent permanent damage to a body structure, either situation suspected to be due to the use of a medical product.

(continued on next page)

SECTION B: ADVERSE EVENT OR PRODUCT PROBLEM *(continued)*

Drugs and Biologics: This box should be checked for important medical events that may be considered a serious adverse experience when, based upon appropriate medical judgment, they may jeopardize the patient or subject and may require medical or surgical intervention to prevent one of the other serious outcomes listed above. Examples of such medical events include allergic bronchospasm requiring intensive treatment in an emergency room or at home, blood dyscrasias or convulsions that do not result in inpatient hospitalization, or the development of drug dependency or drug abuse.

Other: Check only if the other categories are not applicable to the event. Briefly describe the patient outcome in the space provided. The actual narrative of the event will be entered in block **B5**.

B3: Date of event

Provide the actual or best estimate of the date of first onset of the adverse event. If day is unknown, month and year are acceptable. If day and month are unknown, year is acceptable.

When a newborn baby is found to have a congenital anomaly, the event onset date is the date of birth of the child

When a fetus is aborted because of a congenital anomaly, or is miscarried, the event onset date is the date pregnancy is terminated

If information is available as to time during pregnancy when exposure occurred, indicate that information in narrative block **B5**.

B4: Date of this report

The date the report is filled out.

B5: Describe event or problem

For an **adverse event**:

Describe the event in detail, including a description of what happened and a summary of all relevant clinical information (medical status prior to the event; signs and/or symptoms; differential diagnosis for the event in question; clinical course; treatment; outcome, etc.). If available and if relevant, include synopses of any office visit notes or the hospital discharge summary. To save time and space (and if permitted by your institution), please attach copies of these records with any confidential information deleted. **Do not identify any patient, physician, or institution by name. The reporter's identity should be provided in full in section E.**

Information as to any environmental conditions that may have influenced the event should be included, particularly when (but not exclusive to) reporting about a device.

- Results of relevant tests and laboratory data should be entered in block **B6**. (See instructions for **B6**).
- Preexisting medical conditions and other relevant history belong in block B7. Be as complete as possible, including time courses for preexisting diagnoses (see instructions for B7).

If it is determined that reuse of a medical device labeled for single use may have caused or contributed to an adverse patient outcome, please report in block **B5** the facts of the incident and the perceived contribution of reuse to the occurrence.

For a **product problem**:

Describe the problem (quality, performance, or safety concern) in sufficient detail so that the circumstances surrounding the defect or malfunction of the medical product can be understood.

- If available, the results of any evaluation of a malfunctioning device and, if known, any relevant maintenance/service information should be included in this section
- For a medication or special nutritional product problem, please indicate if you have retained a sample that would be available to FDA

B6: Relevant tests/laboratory data, including dates

Please provide all appropriate information, including relevant negative test and laboratory findings, in order to most completely convey how the medical work-up/ assessment led to strong consideration of medical product-induced disease as etiology for clinical status, as other differential diagnostic considerations were being eliminated.

Please include:

- Any relevant baseline laboratory data prior to the administration or use of the medical product
- All laboratory data used in diagnosing the event
- Any available laboratory data/engineering analyses (for devices) that provide further information on the course of the event

If available, please include:

- Any pre- and post-event medication levels and dates (if applicable)
- Synopses of any relevant autopsy, pathology, engineering, or lab reports

If preferred, copies of any reports may be submitted as attachments, with all confidential information deleted. **Do not identify any patient, physician or institution by name.** The initial's reporter's identity should be provided in full in section E.

B7: Other relevant history, including preexisting medical conditions

If available, provide information on other known conditions in the patient (e.g. hypertension, diabetes mellitus, renal/hepatic dysfunction), significant history (e.g. allergies, pregnancy history, smoking, and alcohol use, drug abuse, etc.) and/or race and ethnicity.

SECTION C: SUSPECT MEDICATION(S)

For **adverse event reporting**:

A suspect medication is one that you suspect is associated with the adverse event. In block **C10** enter other concomitant medical products (drugs, biologics, medical devices, etc.) that the patient was using at the time of the event but which you do not think were involved in the event.

Up to two (2) suspect medications may be reported on one form (#1=first suspect product, #2=second suspect product). Attach an additional form if there were more than two suspect medications for the reported adverse event.

For **product problem reporting**:

A suspect medication is the product that is the subject of the report. A separate form should be submitted for each individual product problem report.

Identification of the labeler/distributor and pharmaceutical manufacturer (if known) and labeled strength of the product is important for prescription or non-prescription products.

This section may also be used to report on special nutritional products (e.g., dietary supplements, infant formula or medical foods) or other products regulated by FDA.

If reporting on a special nutritional or a drug product problem, please attach labeling/ packaging if available.

If reporting on a special nutritional only, please provide directions for use as listed on the product labeling.

C1: Name

Use the trade name as marketed. If unknown or if no trade name, use the generic name (with the manufacturer or labeler's name, if known). For quality problem reports, please include the manufacturer's name and the labeled strength for both prescription and non-prescription products.

C2: Dose, frequency & route used

Describe how the product was used by the patient (e.g., 500 mg QID orally or 10 mg every other day IV). For reports involving overdoses, the amount of product used in the overdose should be listed, not the prescribed amount.

See **APPENDIX I** for list of Routes of Administration

C3: Therapy dates

Provide the date administration was started (or best estimate) and the date stopped (or best estimate). If no dates are known, an estimated duration is acceptable (e.g., 2 years) or if therapy was less than one day, then duration is appropriate (e.g., 1 dose or 1 hour for an IV).

C4: Diagnosis for use

Provide the indication for which the product was prescribed or used in this particular patient.

C5: Event abated after use stopped or dose reduced

If available, this information is particularly useful in the evaluation of a suspected adverse event. In addition to checking the appropriate box, please provide supporting lab tests and dates, if available, in block **B6**.

C6: Lot #

If known, include the lot number(s) with all product problem reports, or any adverse event report with a biologic or medication.

C7: Expiration date

Please include if available.

C8: Event reappeared after reintroduction

If available, this information is particularly useful in the evaluation of a suspected adverse event. In addition to checking the appropriate box, please provide supporting lab tests and dates, if available, in block **B6**.

C9: NDC #

The national drug code is requested only when reporting a drug product problem. It can be found on the product label and/or packaging. Zeros and dashes should be included as they appear on the label.

C10: Concomitant medical products and therapy dates

Information on the use of concomitant medical products can frequently provide insight into previously unknown interactions between products, or provide an alternative explanation for the observed adverse event. Please list and provide therapy dates for any other medical products (drugs, biologics, medical devices, etc.) that a patient was using at or around the time of the event. Do not include products used to treat the event.

SECTION D: SUSPECT MEDICAL DEVICE

The suspect medical device is 1) the device that may have caused or contributed to the adverse event or 2) the device that malfunctioned.

In block **D11**, report other concomitant medical products (drugs, biologics, medical devices, etc.) that the patient was using at the time of the event but which you do not think were involved in the event.

If more than one suspect medical device was involved in the event, complete all of section D for the first device and attach a separate completed section D for each additional device.

If the suspect medical device is a single use device that has been reprocessed, then the reprocessor is now the device manufacturer.

D1: Brand name

The trade or proprietary name of the suspect medical device as used in product labeling or in the catalog (e.g., Flo-Easy Catheter, Reliable Heart Pacemaker, etc.). This information may 1) be on a label attached to a durable device, 2) be on a package of a disposable device, or 3) appear in labeling materials of an implantable device. Reprocessed single use devices may bear the Original Equipment Manufacturer (OEM) brand name. If the suspect device is a reprocessed single use device enter "NA".

D2: Type of device

The generic or common name of the suspect medical device or a generally descriptive name (e.g., urological catheter, heart pacemaker, patient restraint, etc.). Please do not use broad generic terms such as "catheter", "valve", "screw", etc.

D3: Manufacturer name & address

If available, list the full name and mailing address of the manufacturer of the suspected medical device. If the answer is Block D8 is "yes", then enter the name and address of the reprocessor.

D4: Product identification number/expiration date

If available, provide any or all identification numbers associated with the suspect medical device exactly as they appear on the device or device labeling. This includes spaces, hyphens, etc.

Model #: The exact model number found on the device label or accompanying packaging.

Catalog #: The exact number as it appears in the manufacturer's catalog, device labeling, or accompanying packaging.

Serial #: This number can be found on the device label or accompanying packaging; it is assigned by the manufacturer, and should be specific to each device.

Lot #: This number can be found on the label or packaging material.

Expiration date (mo/day/yr): If available, this date can often be found on the device itself or printed on the accompanying packaging.

Other #: Any other applicable identification number (e.g., component number, product number, part bar-coded product ID, etc.)

D5: Operator of device

Indicate the type (not the name) of person operating or using the suspect medical device on the patient at the time of the event as follows:

Health professional = physician, nurse, respiratory therapist, etc.
Lay user/patient = person being treated, parent/ spouse/friend of the patient
Other = nurses aide, orderly, etc.

D6: If implanted, give date (mo/day/yr)

For medical devices that are implanted in the patient, provide the implant date or your best estimate. If day is unknown, month and year are acceptable. If month and day are unknown, year is acceptable.

D7: If explanted, give date (mo/day/yr)

If an implanted device was removed from the patient, provide the explant date or your best estimate. If day is unknown, month and year are acceptable. If month and day are unknown, year is acceptable.

D8: Is this a Single-use Device that was Reprocessed and Reused on a Patient?

Indicate "Yes" or "No".

D9: If Yes to Item No.8, Enter Name and Address of Reprocessor

Enter the name and address of the reprocessor of the single-use device. Anyone who reprocesses single-use devices for reuse in humans is the manufacturer of the reprocessed device.

D10: Device available for evaluation?

To evaluate a reported problem with a medical device, it is often critical for the manufacturer to be able to examine the suspect product. Thus, please indicate whether the device is available for evaluation.

Indicate if the device was returned to the manufacturer and, if so, the date of the return. Do not send the device to FDA.

D11: Concomitant medical products and therapy dates

Information on the use of concomitant medical products can frequently provide insight into previously unknown interactions between products, or provide an alternative explanation for the observed adverse event. Please list and provide product names and therapy dates for any other medical products (drugs, biologics, medical devices, etc.) that the patient was using at the time of the event. Do not include products used to treat the event.

SECTION E: INITIAL REPORTER

FDA recognizes that confidentiality is an important concern to health professionals in the context of adverse event reporting. The patient's identity is held in strict confidence by FDA and protected to the fullest extent of the law. However, to allow for timely follow-up in serious cases, the reporter's identity may be shared with the manufacturer unless specifically requested otherwise in block E5. The FDA will not disclose the reporters identity in response to a request from the public, pursuant to the Freedom of Information Act.

E1: Name, address & phone #

Please provide the name, mailing address and phone number of the person who can be contacted to provide information on the event if follow-up is necessary. While optional, providing the contact's E-mail address and/or fax number, would be most helpful, if available. This person will also receive an acknowledgment letter from the MedWatch program.

This information is necessary for both adverse event and product problem reports.

E2: Health professional?

Please indicate whether you are a health professional (e.g., physician, pharmacist, nurse, etc.) or not. If you are not a health professional, please complete block **E3** by filling in NA.

E3: Occupation

Please indicate your occupation (particularly type of health professional), and include specialty, if appropriate.

E4: Also reported to

Please indicate whether you have also notified or submitted a copy of this report to the manufacturer and/or distributor of the product, or, in the case of medical device reports only, to the user facility (institution) in which the event occurred. This information helps to track duplicate reports in the FDA database.

E5: Release of reporter's identify to the manufacturer

In the case of a serious adverse event (see **B1**), the Agency may provide name, address and phone number of the reporter denoted in block **E1** to the manufacturer of the suspect product. If you do not want your identity released to the manufacturer, please put an X in this box.

Subject: New Physiologic Challenge
Importance: High

We have been receiving many questions regarding the new Physiologic Challenge.

First, should every infant enrolled in SUPPORT have at least the PHY01 form completed at 36 weeks? I'm pretty sure the answer this question is yes.

However, here is the problem, we currently have versions of these forms (January 18, 2005) which were sent to the sites. These two forms have now been revised and it's my understanding that they will be implemented along with the New GDB in January. The question is, what forms should the sites be using for current enrollments into GDB and SUPPORT? Should these revised versions be sent out and implemented now?

Thanks for your help in clarifying this.
Betty

Subject: RE: physiologic definition of BPD
Date: Tuesday, October 11, 2005 1:19:38 PM

Rose
In an effort to minimize additional data collection, we were going to use GDB data. We would track this in a similar fashion to GDB. I am not that concerned about this loss, but perhaps you are more aware of how often this data is not available from the GDB database.
I would follow your advice with regard to developing such a mechanism.
Neil

To: nfiner@ucsd.edu; Das, Abhik
Subject: physiologic definition of BPD

Hi Neil and Abhik
Although the physiologic definition is a secondary outcome for SUPPORT, it is not in the manual (according to the coordinators). Do we have a mechanism for tracking this (i.e. missing data on children who have reached status) PHY01 on children alive at 36 weeks??
Thanks
Rose

Hi Rose
I spoke to Barbara
She would like the clarification added to Question number A6 under the possible answers that option #4 read "Only for randomization requirement"
I think that this may help clarify for those sites that have had difficulty in understanding this question.
Regards
Neil

Subject: RE: SUPPORT

Hi Rose
I believe that all centers should respond as is indicated below as
"The site should code #4 if infant was intubated ONLY for study.
The site should code #2 if infant was randomized to intubation but also needed intubation for resuscitation."

We know if the infant is randomized to Surfactant or CPAP from the SUPP 02 eligibility form, and thus if a Surfactant infant requires intubation for resuscitation, this is how form SUPP 03 should be completed. We will then know at the end of the study all Surfactant infants who required intubation for resuscitation, and, in addition, any who were not intubated.
Perhaps I am missing another issue here.
Regards
Neil

To: nfiner@ucsd.edu; Higgins, Rosemary (NIH/NICHD); bkh@rti.org
Subject: SUPPORT

We are having a meeting to review SUPPORT patient charts with my team. A

basic question has arisen:

1--SUPP03--Item A6
Need to clarify reason for intubation in the manual--
After my team thought about this, we think we should code #4 if infant intubated ONLY for study.
Should code #2 if infant randomized to intubation but also needed intubation for resuscitation.

If we code #4 for all infants randomized to intubation, we lose information on reason for resuscitation on those who also needed resuscitation

Please clarify
Thanks

Has anyone received any revisions of protocol, questionnarire, or consent template from Tim Stevens pursuant to the issues raised, recommendations made, and matters agreed during his presentation/discussion several weeks ago at our meeting in Virginia? Among other things, I thought he agreed to drop the PCP chart audit, and make some modifications to the questionnaire and consent. Carolyn, I think you or Jaimie were taking notes during this discussion. What do you show as follow-up items? We were holding out taking this to our IRB until these issues are resolved. But time is running out. Thanks.

Attachments: SUPP_GRO 01 form.doc

Hi Rose,

Please take a look at the data collection form that Cristina came up with. She took the Glutamine data collection form that many of the coordinators are already familiar with and modified it so that the anthropometric data and nutrrition data are on the same sheet. Much of the anthropometric data are already collected for GDB at some of the listed time points, but I recall from our last meeting that the coordinators preferred to have all data for a particular study on the same sheet. Ruth helped us with the sheet and thought it should meet coordinator needs - 1 sheet per baby per day of data collection.

Hope it looks OK to you. What do we do next - does she need a working group? If she does, I would suggest Richard, Brenda, Seetha (who has expressed an interest in the IUGR sub-group) and Neil. Also, when do we need the Manual of Operations by? The Savannah meeting? Ruth pulled out our premie board - its not bad ... a fairly light plexiglass gizmo about 6 inches wide and 24 inches long which she will bring to GA for the demo.

We are very excited to be starting and hope some good information comes out of the effort

Shahnaz

Shahanaz

I like the growth secondary a lot.
My only comment:
Infection plays a role in growth failure, BPD and adverse ND outcome. Our recent JAMA paper showed a nice association with poor growth (is nice a good word in this context). I suggest that we evaluate the added impact of infection. You could include proven sepsis in the model, etc. I would love to work on this with you.

HI,
I need a vote from the PI's regarding the SUPPORT GROWTH SECONDARY presented by Dr. Duara last week at the steering committee meeting.

Please indicate your preference:

1. Yes – this needs to go forward without additional funding and should start now
2. Yes – this needs to go forward and we should commit funds from the 2006 budget (this will impact the possibility of other protocols being instituted)
3. No – this needs to wait for the next budget period with reassessment in April 2006
4. No – this should not be done

I have attached the protocol.
Send me your vote by September 30.

Thanks
Rose

That would be fine, and may even be more that I need. 5X16 = 80. or maybe that's about right.

It is far more important that I see some soon and do education/update/revision early.
It would be very sad to discover problems only after all 16 centers have turned in at least 5 data sheets. (which will be a long time from now).

I would think that if you can give me about 10 (you can block center number), I can get a pretty good first impression.

I am doing a short talk on ROP coding at the coordinators GDB meeting in Nov. on the 14th. If I can learn from these dataforms, I will know better what to do for the coordinators in Nov.

Rose,
This is probably fine (will check with Neil, but we should not capitalize Support, as it may confuse the issue. We don't want them to think that if they are on <500cc flow they are not in the Support trial at all.

HI, can we state :
Our definition is that ≤ 500 ml/min flow by itself, ie without oxygen, is not considered as Support **for the purposes of the trial definition**. Therefore an infant receiving such flows, 500ml/min or less, should have the study oximeter removed after 3 days.

Neil
For the definition in the manual for "high flow" for the technical memo: If an infant is on 500 ml or less of room air, how long does the infant stay on the study pulse oximeter (does the 3-day (72 hour) guideline apply to these infants). Bottom line is 500 ml room air nasal cannula considered support??
Kris needs this ASAP for the technical memo.
Thanks
Rose

Erica,

Yes. Two blue oximeters will go out today if I hurry. If not, early tomorrow am.
Is the address below appropriate for shipping?

Wade

Subject: Re: SUPPORT Oximeters

Hi Dr. Higgins,
We have a little dilemma here. We have enrolled another SUPPORT baby today and the baby randomized to the blue arm of the Oximeter portion of the study. This happens to be our last blue oximeter. We have placed an order for another set of oximeters, but that may be some time before it is finalized and arrives here. In the mean time we are in need of at least one blue oximeter and preferably two. I am not sure who I should be contacting to possibly have a couple over-night shipped to us. Linda Reubens is out sick today and I know we contacted you the last time we had an issue with the oximeters. Can you help me with this?

Thank you,

Erica Burnell

Subject: SUPPORT Follow-up MOO-First Draft
Date: Tuesday, September 27, 2005 12:57:00 PM
Attachments: SUPPORTFUMOOjn9_26.doc

Attached is the Support Follow-up Manual of Operations (MOO) that I have drafted. This document was created by using the SUPPORT Trial Manual as a template and updating it with information from the SUPPORT Follow-up Protocol. Therefore, there may be sections that we want to delete and other sections to elaborate upon or add. Highlighted in yellow are areas of uncertainty. This document has not been formatted so please do not spend time formatting the document, RTI has administrative support people that can help with this (including updating the table of contents). However, I did not want formatting to delay in getting you something to work with since it is the first draft.

Here are some items that still need to be addressed:
-Add question by question definitions when the forms are forms are deemed nearly final
-Confirm subcommittee names—Will there be a specific SUPPORT FU subcommittee or will the SUPPORT subcommittee or FU PIs oversee the study?
-We will want to be consistent and use either "follow-up" or "follow-on" throughout the documents
-I will confirm that all of the acronyms in the list in Appendix A appear in the text
-I'd like to include Figure 1 on page 9 of the Protocol in the MOO (maybe Section 5.1) because it describes the study well. However, I had problems getting it into the document.
-I'd like to go back through my notes from the specifics of the SC meeting to make sure I didn't miss anything.

Please let me know areas/sections that need additional information.

Thanks, Jamie

SUPPORT Trial Follow-up Study of Pulmonary Outcomes

The SUrfactant Positive Airway Pressure and Pulse Oximetry Trial in Extremely Low Birth Weight Infants (SUPPORT Trial)

NICHD Neonatal Research Network

Manual of Operations

September 27, 2005

TABLE OF CONTENTS Needs to be updated

Chapter 1

Overview and Trial Design

1.1 Introduction

This manual provides detailed instructions of study procedures for the Follow-up Study of the NICHD SUPPORT Trial Follow-up Study (The SUrfactant Positive Airway Pressure and Pulse Oximetry Trial in Extremely Low Birth Weight Infants). This manual should be used as a reference guide for study staff including investigators, coordinators, technicians, and data managers. The trial objectives and design are summarized briefly below. For further discussion to the study background and design, please refer to the Follow-up Study Protocol.

1.2 Study Design

This study is a longitudinal follow-up of surviving infants enrolled, randomized and treated as part of the SUPPORT Trial, which was a prospective, randomized, factorial 2X2 design multi-center trial conducted by the NICHD Neonatal Research Network. This follow-up study will determine the effect of lower targeted oxygen saturation ranges and more aggressive use of CPAP on the incidence of symptomatic airway dysfunction and volume of outpatient care in the first 18-22 months corrected age (CA). The individual factors to be tested in this follow-up study are:

1) Symptomatic airway dysfunction and need for outpatient pulmonary care in the first 18-22 months among infants managed with a lower SpO2 range (85% to 89%) as compared to a higher, more conventional SpO2 range (91% to 95%).
2) Symptomatic airway dysfunction and need for outpatient pulmonary care in the first 18-22 months corrected age among infants managed with CPAP and a permissive ventilatory strategy versus infants managed with prophylactic surfactant and conventional ventilation begun in the delivery room and continuing in the NICU.

Table 1 below describes the the study treatment groups. Refer to the SUPPORT Trial Protocol for further details regarding the projected outcomes relative to the study interventions

Table 1: SUPPORT Trial Study Treatment Groups

Randomized Intervention	**Low SpO2 85% to 89%**	**High SpO2 91 to 95%**
Treatment **Early CPAP**	Early CPAP + Low SpO2	Early CPAP + High SpO2

Control **Prophylactic/Early Surfactant**	Control + Low SpO2	Control + High SpO2

1.4 Primary Hypotheses

1) We hypothesize that that relative to infants managed with a higher SpO2 range (91% to 95%), infants managed with a lower SpO2 range (85% to 89%) will have less frequent episodes of symptomatic airway dysfunction and reduced need for outpatient pulmonary care at 18-22 months' CA.

2) We hypothesize that relative to infants managed with prophylactic surfactant and conventional ventilation, infants managed with early CPAP and permissive ventilator strategy will have less frequent episodes of symptomatic airway dysfunction and reduced need for outpatient pulmonary care in the first 18-22 months' CA.

1.5 Secondary Hypotheses

1) We hypothesize that **among infants with CLD**, infants managed with a lower SpO2 range relative to those managed with a higher SpO2 target range will have less frequent episodes of symptomatic airway dysfunction and reduced need for outpatient pulmonary care during the first 18-22 months' CA.

2) We hypothesize that **among infants without CLD**, infants managed with early use of CPAP and permissive ventilator strategy relative to infants managed with prophylactic surfactant and conventional ventilation will have less frequent episodes of symptomatic airway dysfunction and reduced need for outpatient pulmonary care during the first 18-22 months' CA.

1.6 Summary of Data Forms

The following is a summary of the data forms used in this study. Further details on each form are provided in subsequent chapters. A complete set of forms can be found in Appendix A.

NICU Discharge-Baseline Interview (SUPF01)
This interview will be administered to the parent or guardian by a trained study nurse prior to NICU discharge. Questions concerning family medical history, anticipated living arrangements, and alternate contact information will be asked.

6 Month and 12 Month Interview (SUPF02)
This interview will be administered to the parent or guardian by a trained telephone interviewer at 6 months' CA and again at 12 months' CA.

18-22 Month Interview (SUPF03)

This interview will be administered to the parent or guardian by a trained telephone interviewer at 18-22 months CA. Questions have been added to the 6 month interview concerning the child's allergies.

Chapter 2

Administration

2.1 Organizational Structure

The NICHD Neonatal Research Network is conducting this study. The Network is funded by the NICHD under cooperative agreements with seventeen institutions comprised of sixteen clinical centers and a data coordinating center. The Steering Committee for the Network consists of the Principal Investigator from each clinical center, the data center, and the NICHD project officer. The Steering Committee Chairman is appointed by NICHD and is not a Principal Investigator from any of the Clinical Centers.

2.2 SUPPORT Trial Follow-up Subcommittee ??Check to confirm??

Will there be a SUPPORT Trial Follow-up Subcommittee? This is what was included in the SUPPORT MOO:
The SUPPORT Protocol Subcommittee is responsible for the preparation and maintenance of the protocol, data forms, and manual of operations. This subcommittee will monitor the overall study performance (including protocol compliance) and will report the progress of the trial to the Steering Committee. SUPPORT Subcommittee members are:

Neil Finer, MD

Waldemar A. Carlo, MD,

Edward F. Donovan MD

Michele Walsh, MD

Shahnaz Duara, MD

Rosemary D. Higgins, MD

Abhik Das, PhD

Ruth Everett, RN

Wade Rich, RRT

I see on the cover page of the SUPPORT Follow-up Protocol that the following names are listed. Drs. Stevens and Szilagyi are not mentioned in the SUPPORT MOO so this will need to updated for the Follow-up Study.
Timothy P. Stevens, MD, MPH
Peter Szilagyi, MD, MPH
Dale Phelps, MD

2.3 Participating NICHD Neonatal Research Network Centers

Centers from the NICHD Neonatal Research Network participating in the trial are listed below. The NICHD center number is indicated in parentheses next to the name of each center and the Neonatal Research Network principal investigator is located in the second column. **Should we add another column for the SUPPORT Follow-up PI? Will there be Follow-up PIs for SUPPORT or will the NRN Follow-up PI's monitor this study? Confirm names**

PARTICIPATING CENTERS	NRN PI	SUPPORT STUDY PI
Case Western Reserve Univ. (3) Rainbow Babies and Children's Hospital	Michele Walsh, MD	Michele Walsh, MD
University of Texas-Dallas (4)	Charles Rosenfeld, MD	Walid Salhab, MD
Wayne State University (5) Children's Hospital of Michigan	Seetha Shankaran, MD	Seetha Shankaran, MD
University of Miami (8) Jackson Memorial Hospital	Shahnaz Duara, MD	Shahnaz Duara, MD
Emory University (9) Grady Memorial Hospital	Barbara J. Stoll, MD	Susie Buchter, MD
University of Cincinnati (11) University of Cincinnati Hospital	Edward F. Donovan, MD	Vivek Narendran, MD Kurt Schibler, MD
Indiana University (12)	James A. Lemons, MD	Brenda Poindexter, MD
Yale University (13) The Children's Hospital at Yale – New Haven	Richard A. Ehrenkranz, MD	Vineet Bhandari, MD
Brown University (14) Women and Infant's Hospital	William Oh, MD	Abbot Laptook, MD
Stanford University (15) Stanford University Med Center	David K. Stevenson, MD	Krisa Van Meurs, MD
University of Alabama (16) University of Alabama at Birmingham	Waldemar A. Carlo, MD	Waldemar A. Carlo, MD
University of Texas- Houston (18)	Jon E. Tyson, MD	Brenda Morris, MD
Duke University (19)	Ronald Goldberg, MD	C. Michael Cotten, MD
Wake Forest University (20)	Michael O'Shea, MD	Michael O'Shea, MD
Golisano Children's Hospital at Strong (21) University of Rochester	Dale L. Phelps, MD	Nirupama Laroia, MD
University of California-San Diego (22)	Neil Finer, MD	Neil Finer, MD

2.3 Responsibilities of the Clinical Centers

The minimum staff required for network participation at each clinical center is the physician Principal Investigator (PI), the Research Coordinator, **and telephone interviewers, if interviews are not conducted by the Research Coordinator.** [redacted] The responsibilities of these individuals are described briefly in this chapter and in more detail in subsequent chapters.

The PI or designee is responsible for ensuring the proper conduct of the trial at his or her clinical center (including recruitment and treatment of patients as specified in the protocol), accurate collection of data and transmission of information to the Data Coordinating Center (DCC). Other specific duties include the following:

- Presenting an in-service to the other physicians
- Applying for IRB approval
- Introducing the study to the parents of prospective patients, and obtaining signed informed consent from the parents of eligible infants (in some centers this responsibility may be delegated)
- Reviewing all infants for whom informed consent has been obtained to confirm their eligibility
- Informing the IRB of the study progress.

The Research Coordinator will be responsible for the day-to-day operations of the study at the clinical center, including data collection and management. This responsibility includes the following:

- Collecting information necessary to complete the data collection forms, and coordinating data entry
- Training and certifying the staff in the use of the network computer
- Controlling access to the network computer and ensuring that required back-up, security and confidentiality are maintained
- Responding to edit messages and other communications from the data center
- Distributing updates of the protocol and of the manual of operations to clinical center staff
- To facilitate patient tracking, Network Centers choosing Rochester to administer questionnaires to their patients (Option 2) will provide contact information to the Rochester site.

2.4 Responsibilities of the University of Rochester Health Services Research Group

Clinical Centers will have the option of administering the follow-up questionnaires to their own patients (Option 1) or having telephone interviewers of the University of Rochester Health Services Research Group administer the follow-up questionnaires to their patients (Option 2). Regardless of the option chosen, each local center will be responsible for obtaining informed consent, administering the discharge questionnaire, and tracking patients following discharge.

In efforts to standardize the administration of the interviews, the University of Rochester Health Services Research Group will be responsible for a program to train interviewers at various centers. To standardize administration of the interview, a program to train interviewers will be undertaken. The program will consist of two parts. Part 1 consists of creation of a videotaped, structured interview in which the Rochester Trainer interviews a simulated patient. The training video will then be distributed and viewed by interviewers at each center. Part 2 will consist of a practice interview in which interviewers from each center interview the Rochester trainer, who simulates a standardized patient. Following the practice interview, the Rochester trainer and practice interviewer will discuss the interview and give feedback. Other responsibilities include:

- Development and distribution of an audio clip of wheezing to be presented along with a verbal definition to the interview respondent to standardize interpretation of wheezing and to minimize ascertainment biases due to language, culture, literacy or interviewing techniques.
- Maintaining trained Spanish-speaking individuals to conduct the telephone interviews with Spanish-speaking participants from centers choosing Rochester to administer the questionnaire to their patients (Option 2).
- Spanish language versions of the questionnaires will be created and made available to all centers. The Cornell Translation Service, a University based professional translation service, will be contracted by the University of Rochester to perform the translation.

2.5 Responsibilities of the Data Coordinating Center

The DCC at RTI International is responsible for all aspects of statistical design and analysis as well as data management of the study. In particular, this includes:

- Processing, updating and distributing the protocol and manual of operations
- Developing and distributing the data forms, including periodic updates as necessary
- Developing, testing and implementing the database and other software. Ensuring that data are correct and complete by implementing editing and auditing procedures
- Monitoring the progress and quality of the study
- Preparing interim and final analyses and reports
- Participating in the preparation of presentations and publications relating to the study

The DCC is also responsible for sending monthly reminder reports to Network Centers. ***Check with RTI Research Computing Division to confirm the following:*** For each enrolled patient, the report will include the following:

- Network number
- Gestational age
- Gender
- Date of last interview
- Answer to question 1 (care taker providing the previous interview)
- Answer to 1a (was interview conducted face to face or by telephone)
- List which of the 4 interviews have been completed (CA = corrected age)
- Completed interviews, date of last interview and answers to question 1 and 1a may be presented as outlined in the table below.

Example table

Required Interviews	Date	Caretaker Interviewed	Face to Face?
▪ Discharge	__/__/__	_____	Y or N
▪ 6 month CA	__/__/__	_____	Y or N
▪ 12 month CA	__/__/__	_____	Y or N
▪ 18-22 month CA	__/__/__	_____	Y or N

- Target date for the current interview with windows within which interview should be accomplished, goal window (target date ± 2 weeks) and acceptable window (target date ± 4 weeks)
- A "postcard date", 5 weeks prior to the contact, when a postcard might be sent to the family reminding them of the upcoming call or visit

2.5 Responsibilities of NICHD

In addition to its role as a funding agency, the NICHD participates in the activities of the cooperative agreement by being represented on the Steering Committee. The Program Official also participates in the development of protocol and in assisting the Steering Committee in the coordination of the studies conducted by the Network. The NICHD Program Official, in conjunction with the RTI Principal Investigator is responsible for monitoring site performance of all participating centers. The Program Official has the following responsibilities:

- Assistance in the development of the study protocol.
- Assistance in the development of capitation-based budgets, including the identification of study costs and special institutional needs.
- Allocation of network resources to meet study needs.
- Facilitation of training meetings, site visits, and subcommittee meetings.
- Participating in preparation of publications.

Chapter 3

Screening, Eligibility, Consent

3.1 Study Population

This follow-up study will include all surviving infants enrolled, randomized and treated as part of the multi-center NICHD Neonatal Research Network SUPPORT Trial, which were inborn infants of 24 0/7ths to 27 6/7th weeks at birth for which a decision was made to provide full resuscitation as required. Infants 27 weeks or less gestation (completed weeks by best obstetric estimate) were enrolled.

3.2 Inclusion Criteria

- Full resuscitation as necessary, i.e., no parental request or physician decision to forego resuscitation
- Parents/legal guardians have provided consent for enrollment
- No known major congenital malformations
- Survival to hospital discharge

3.3 Exclusion Criteria

- Transport to the center after delivery
- Research apparatus/study personnel are not available.

3.4 Informed Consent

Every effort will be taken to enroll ALL SUPPORT Trial patients into the Follow-up Study, including currently enrolled SUPPORT patients (both patients still in NICU and those discharged) and future enrollees. By obtaining pulmonary outcome data for both current and future SUPPORT patients, death or adverse pulmonary outcome can be analyzed as competing outcomes. Each local center will be responsible for obtaining informed consent for the Follow-up Study regardless of whether they are administering the follow-up questionnaires to their patients or Rochester is conducting the telephone interviews.

For future enrollees in the SUPPORT Trial, consent for the Follow-up study will be obtained at the time of enrollment in the main trial. As described in the SUPPORT Trial Manual of Operations, these infants will be recruited for the study by approaching one or both parents at the time of admission to the hospital at risk for premature delivery at 27 weeks or less. It is anticipated that, whenever possible, the parents will be approached by study personnel to discuss the trial and obtain an informed consent for the participation of the infant at delivery. Randomization will be by family, thus all offspring will be randomized to the same trial arms, provided adequate equipment and personnel are available at the time of delivery. Sample consent forms for currently enrolled and future SUPPORT patients are attached (Appendix C).

3.5 Screening Procedures

This follow-up study will include all surviving infants enrolled, randomized and treated as part of the NICHD Neonatal Research Network SUPPORT Trial.

For future enrollees in the SUPPORT Trial, all admissions for threatened premature delivery will be screened on a daily basis to ensure that eligible patients can be enrolled. Obstetrical colleagues at each participating institution will be informed of the nature of this study and encouraged to discuss this study with their patients at risk of premature delivery. The study coordinator at each site will maintain a screening log of potentially eligible patients. In addition, the usual practice of neonatal consultation for all such at risk deliveries will provide a second opportunity to approach mothers with fetuses at risk of preterm delivery.

Chapter 4

Randomization

4.1 Randomization Procedures

Randomization for the NICHD Neonatal Research Network SUPPORT Trial was stratified by gestational age group (24 - 25 6/7 and 26 - 27 6/7) and occurred prior to delivery for consented deliveries. The randomizations were performed by utilizing specially prepared envelopes. The Data Center prepared brown sealed envelopes which contained the identity of the treatment combination that were assigned to the infants enrolled into the study. Deliveries were randomized as a unit, thus multiples, twins, triplets etc were randomized to the same arm of the trial. One envelope corresponded to the delivery of a consenting mother regardless of the number of babies delivered so that all babies from a given delivery received the same treatment combination.

Refer to Section 4.1.1 of the NICHD Neonatal Research Network SUPPORT Trial Manual of Operations (MOO) for more information on randomization and masking as well as storing and assigning oximeters that occurred during the main study.

During the Follow-up Study activities, research coordinators and telephone interviewers, if different from the research coordinators, will remain blinded as to whether infants were randomized to the control or treatment group.

Chapter 5

Follow-up Study Procedures

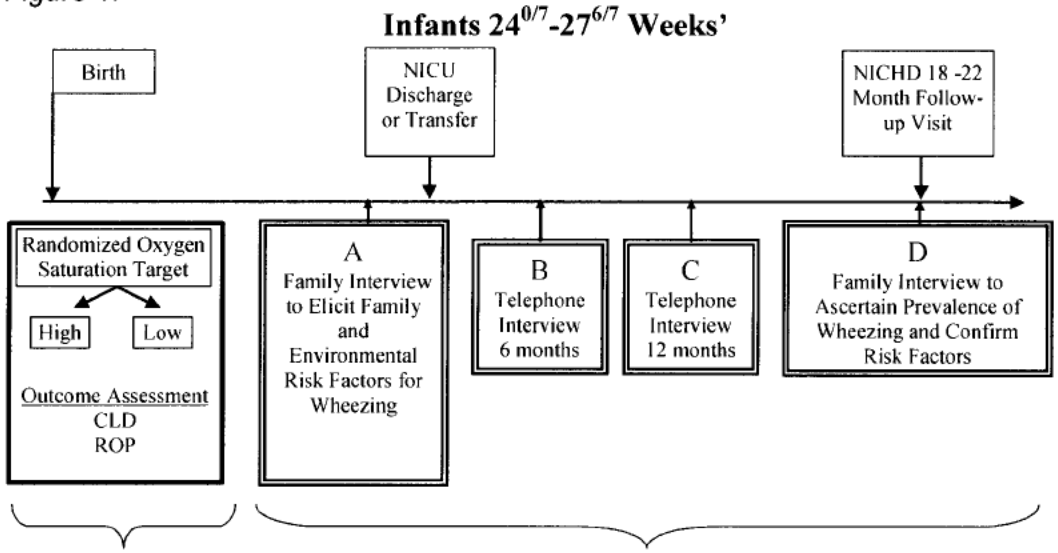
5.1 Study Interventions

Refer to Chapter 5 of SUPPORT Trial Manual of Operations (MOO) for more information on the study interventions and the procedures for the treatment groups. The same questionnaires will be administered to both treatment groups in the Follow-up Study.

Before delivery, infants will be randomized to subsequent management with high vs. low target oxygen saturation according to the SUPPORT Protocol. The SUPPORT Follow-on Study of Pulmonary Outcomes begins just prior to NICU discharge. See Figure 1 for a diagram of the SUPPORT Trial

SUPPORT Trial Follow-on Study

Figure 1.



Follow-up Study procedures. **(Insert Figure 1 of SUPPORT Follow-up Protocol here).**

5.2 Administration of the Follow-up Questionnaires

The target date for conducting the interviews is ± 2 weeks, however, the acceptable window for conducting the interviews is ± 4 weeks.

Clinical Centers have the option of administering the follow-up questionnaires to their own patients (Option 1) or having telephone interviewers of the University of Rochester Health Services Research Group administer the follow-up questionnaires to their patients (Option 2). Table 2 indicates which option the centers have chosen.

	Local Center	Local Center	Rochester
Consent	✓	✓	
Questionnaire at Discharge	✓	✓	
Patient Tracking	✓	✓	
Questionnaire at 6 & 12 mo.	✓		✓
Questionnaire at 18-22 mo.	✓		✓
Data Entry (questionnaires)	✓		✓

Table 2. **SUPPORT Trial - Pulmonary Outcomes Study**

6, 12 and 18-22 Month Pulmonary Questionnaires

NICHD Site	*Administered By*	*Option Number*
Alabama	Alabama	1
Brown	Brown	1
Cincinnati	Cincinnati	1
CWRU	CWRU	1
Dallas	Dallas	1
Duke	Duke	1
Emory	Rochester	2
Houston	Rochester	2
Indiana	Rochester	2
Miami	Miami	1
Rochester	Rochester	2
Stanford	Rochester	2
UCSD	UCSD	1
Wake Forest	Wake Forest	1
Wayne State	Wayne State	1
Yale	Yale	1

Regardless of the option chosen, each local center is responsible for obtaining informed consent, administering the NICU Discharge-Baseline Interview (SUPF01), and tracking patients following discharge. Table 3 further describes the responsibilities of the local center and Rochester in Option 1 and Option 2. **Reformat and insert Figure 2 from Protocol as Table 3 here.**

5.2 Protocol Violations

The occurrence of any one of the following criteria will determine whether an individual infant will be considered a protocol violation:

1. **Are there protocol violations expected in the FU study? i.e., Starting the interview within the FU window but completing it after the window has expired**

All protocol violations will be reviewed by the center PI who will discuss each protocol violation with the involved clinicians [redacted]

[redacted]

5.3 Adverse Events

Serious and unanticipated adverse events were anticipated in the main study for this vulnerable population. Data on potential adverse events that could have potentially been related to the study maneuver were recorded and evaluated as part of continuous safety monitoring during the trial by RTI. Refer to Section 5.5 of the NICHD Neonatal Research Network SUPPORT Trial MOO for more information on adverse event reporting and monitoring.

Will any adverse events noted (i.e. death of child since last contact) during the interviews need to be reported or recorded as AE's? If yes, will RTI need to continue monitoring AE's in terms of treatment groups in the FU as was done in the main study?

Chapter 7

NICU Discharge-Baseline Interview

7.1 Instructions for completing the NICU Discharge-Baseline Interview (SUPF01)

This interview should be administered to the parent/guardian by a trained study nurse prior to NICU discharge.

Heading- Infant's Identification

The following information is included in the heading section of all patient specific data forms: Center, Site, Network Number, Birth Number and Mother's Initials **(optional). Confirm header information**

Chapter 8

6 and 12 Month Pulmonary Outcome Questionnaires

The same questionnaire will be administered by telephone to the child's parent or guardian at 6 and 12 months' CA to assess pulmonary outcomes. These interviews will be administered to the parent or guardian by a trained telephone interviewer at 6 and 12 months' CA.

The interviewer should advise the parent or guardian to call his/her child's doctor if concern about a health issue is raised during the interview.

8.1 Instructions for completing the 6 Month and 12 Month (SUPF02) Pulmonary Outcome Questionnaires Needs to be Updated

Chapter 9

18-22 Month Questionnaire

This questionnaire will be administered by telephone to the child's parent or guardian at 18-22 months CA to assess pulmonary outcomes.

The interviewer should advise the parent or guardian to call his/her child's doctor if concern about a health issue is raised during the interview.

Update the following sections

9.1 Instructions for completing the 18-22 Month Questionnaire (SUPF03)

APPENDIX A

List of Acronyms

BOOST Trial – Benefits of Oxygen Saturation Targeting
BPD – Bronchopulmonary Dysplasia
CA – Corrected Age
CLD – Chronic Lung Disease
CPAP – Positive pressure applied with a face mask to help keep lungs inflated
FEF – Forced Expiratory Flow
GA – Gestational Age
GDB – Generic Data Base for the NICHD Neonatal Research Network
HDMA – House Dust Mite Allergen
HIPPA – Health Insurance Portability and Accountability Act of 1996
HSR Group – University of Rochester Health Services Research Group
IRB – Institutional Review Board
LBW – Low Birth Weight
NBW – Normal Birth Weight
NHLBI Consensus Expert Report -
NICHD – The National Institute of Child Health and Human Development
NICU – Neonatal Intensive Care Unit
PFT – Pulmonary Function Testing
RDS – Respiratory Distress Syndrome
ROP – Retinopathy of Prematurity
RSV - Respiratory Syncytial Virus
SP02 –
SUPPORT Trial– The SUrfactant Positive Airway Pressure and Pulse Oximetry Trial in Extremely Low Birth Weight Infants
UKOS – The United Kingdom Oscillator Study
VLBW – Very Low Birth Weight

Subject: Re: SUPPORT GROWTH SECONDARY
Date: Monday, September 26, 2005 1:08:16 PM

Rose,
Indiana votes for #1. We will put this through as an amendment to SUPPORT for the additional data collection so that we don't need an additional consent form (like Neil, we will have a separate consent for the MRI secondary).
Brenda

HI,
I need a vote from the PI's regarding the SUPPORT GROWTH SECONDARY presented by Dr. Duara last week at the steering committee meeting.

Please indicate your preference:

1. Yes – this needs to go forward without additional funding and should start now
2. Yes – this needs to go forward and we should commit funds from the 2006 budget (this will impact the possibility of other protocols being instituted)
3. No – this needs to wait for the next budget period with reassessment in April 2006
4. No – this should not be done

I have attached the protocol.
Send me your vote by September 30.

Thanks
Rose

Date: Thursday, September 22, 2005 5:00:36 PM

The PHY forms are not approved for any research protocols in my institution except for SUPPORT. PD is no longer an approved protocol. I can not reference an amendment to the GDB protocol saying we will collect this form if the protocol amendment itself does not exist. I do not see how we could get approval to send the data to RTI until the GDB protocol containing a reference to the PHY forms is finalized.
Wade

Subject: Re: Physiologic Definition

If the physiologic definition data are collected as part of an approved protocol (I.e. Support), then they can be transmitted to rti. If these data are collected as part of GDB, the Approval must be requested as an ammendment to GDB UNTIL WE HAVE THE NEW PROTOCL READY FOR DISSEMINATION IF the data are transmitted to rti.

Thanks
Rose.

Subject: Re: Physiologic Definition

We have been transmitting data related to the physiologic definition (on babies enrolled in SUPPORT and on babies not in SUPPORT) to RTI. Lucy has told me that this is on a separate data form. If this is not a part of GDB, then we do not have IRB approval to be sending this data. We should either have all sites make an immediate amendment to GDB to include the physiologic definition - or should wait to send any data related to the physiologic definition on non-SUPPORT babies until after the revised GDB is approved by our IRBs. We should be okay on babies enrolled in the SUPPORT trial because the physiologic definition is mentioned in the protocol. Please advise how you want us to proceed - it sounds like many sites have the same concern.
Thanks, Brenda

Subject: SUPPORT, high flow NC, etc
Date: Thursday, September 22, 2005 1:36:22 PM

Neil,

I know the subject of high flow nasal cannuals and the SUPPORT Trial has been a topic of discussion for many months. I do find that we seem to have an everchanging definition..... such as (1) in the January 6th e-mail Q&A on SUPPORT, high flow nasal cannula was defined as 1 liter or greater, (2) the coordinators minutes dated April 25th, state that for the purpose of the survey on the use of high flow nasal cannuals---- the definition was 1/2 liter or greater, (3) Tech Memo 2 of May 5th instructs us to use the definiton of >500cc/min to define "support" (room air nasal cannula) for the SUPP11 form, and (4) during discussions at our recent steering committee meeting high flow was defined as 2 liters per minute.

Could we please have a *Tech Memo* (#4) issued that presents the current definition of high flow nasal cannula? This would help to appease our staff, our IRB's and make sure that we all were consistent with the use of that definition in our practices throughout all 16 centers (and the definition of high flow NC varies from site to site------Would also help us to know if we have to complete a study deviation form). **In addition, it would be helpful if you included a statement about disabling the high alarm on the study oximeter when the infant is on room air and it is constantly alarming (our recent experience and your instructions** -------same reasons -- makes staff and IRB's feel comfortable that we are following study protocol).

I do need some clarification of the use of NC/hood, (Form SUPP05). The instructions are: "Complete section B if infant is on cannual/hood for > 8 hours on this day". Is that 8 hours total use in a day, or NC/hood used for an 8 hour time period? Our study infant received 400cc NC for 3 hours yesterday as the nares were pink....but no skin breakdown. If there is a temporary switch to NC or hood to help preserve skin integrity...do we only answer that question if it is for 8 consecutive hours or for 8 cumulative hours? (Infant continues to do well and has had an occasional oxygen requirement to 30%, but remains primarily on RA. This has been great for acceptance of the study as it has provided a positive response to using early CPAP in these small infants.)

At our center we may on occasion transfer an infant from site 1 to site 2 (census reasons, requirement for PDA ligation, ROP surgery, and that nemesis NEC). We cannot transport the oximeter with the infant as each hospital requires that their own bio-med people do the electrical check on the unit before it can be used. There may be some times that we may not have an oximeter at Site 2 and have to borrow one and wait for a check before it can be put into use. What is the time period allowed for the infant to be off of a study oximeter before we compete a protocol deviation" Two hours ....like the protocol for initial admission to the nursery? This would also apply to those infants that come off of oxygen, have their oximeter discontinued after 72 hours, go back on oxygen....and require a study oximeter because they have not reached the 36 wks date. **We need a statement about time between going back on oxygen and application of study oximeter before protocol deviation** --- ***plus a definitive statement of how many hours in a 24 hour clock on oxygen before study oximeter must be replaced on infant (four hours of oxygen therapy?, eight hours?, 12 hours?) needs to be included in a Tech Memo.***

Thank you for making yourself available to answer our questions. Many of these things we discuss in meetings and on conference calls. It would be so helpful if they could then be summarized and sent to us as a Tech Memo or FAQ update so that we can have clear guidelines to put into practice.

Nancy P.

Abbot
The vote for the growth secondary is "as is" but suggestions can be passed along. For the SUPPORT pulmonary secondary study, there was a brief survey at discharge which I thought was included with prior versions – up to the sites who does it.

Thanks
Rose

Rose
I heard a number of concerns regarding this protocol that I think need to be addressed. Specifically there is the concern about the safety of doing length measurements on fragile infants during the first few weeks of life when their respiratory status is tenous. The other issue is the frequency of the measurements and whether we really need weekly meaurement of head and length during the first month of life. Will this be clarified or are we voting for the protocol as is?
A second unrelated issue is the pulmonary survey for the support trial. Previous versions started with surveys at 6 months as I recall but I now see that the recent version is expected to start prior to discharge. I guess I missed when this happens but was this discussed or mentioned? I don't recall hearing about it. It does impact who will be doing the initial survey ie coordinator or follow-up personnel. We were viewing this as something that could totally be done as part of follow-up when the mother comes in. Can you bring me up to speed on this one? Tx, AL

Post-natal Growth of Infants Enrolled in the NICHD Neonatal Network Oxygen Saturation (SUPPORT) Study: A Proposed Secondary Study

Cristina Navarrete MD, and Shahnaz Duara MD
University of Miami Miller School of Medicine, Miami, FL.

Abstract:

Post-natal growth restriction is a major problem in preterm infants. Perturbations in oxygenation are recognized to influence post-natal growth; hypoxic conditions can directly impair growth and hyperoxic conditions predispose infants to BPD, which in turn has been linked to poor growth. The NICHD Neonatal Network is conducting a prospective trial of preterm infants randomized to two levels of baseline oxygen saturations. The effect of baseline saturations on pulmonary morbidity and ROP are the primary outcome measures. With respect to post-natal growth, there is a paucity of data relating alterations in baseline oxygen saturation and/or frequent deviations above or below the baseline to growth outcomes. We propose a secondary study to quantify short-term growth velocity in-hospital and long-term growth at 18-22 months of corrected age for infants enrolled in the SUPPORT Trial in relationship to oxygen saturation.

A. Hypothesis to be tested

Primary:

1. Infants in the low oxygen saturation group (85-89%) will have better in-hospital and long-term (18-22 months corrected age) growth.

2. Trajectories of growth in hospital will be better for infants in the low oxygen saturation group.

Secondary:

1. Growth will be greater in infants who spend > 50% of the time with daily median oxygen saturation between 85% -95% while on supplemental oxygen, independent of randomization to low or high oxygen saturation.

2. Infants with BPD will have poorer in-hospital and long-term growth than infants without BPD, independent of the saturation randomization arm.

3. Better long-term growth will be positively related to neuro- developmental outcome, independent of the saturation randomization arm.

B. Specific Aims:

1. To determine anthropometric measurements (wt, HC, length) in infants randomized to low and high oxygen saturation arms, from birth to hospital discharge and again at 18-22 months corrected age.
2. To determine nutritional intake (parenteral and enteral) during hospital stay.
3. To determine the percentage of infants with growth <10 percentile at 36 weeks PMA or discharge, whichever comes first.
4. To determine the percentage of infants with growth <10 percentile at 18-

22 months corrected age.

5. To determine growth in relation to the proportion of time spent with oxygen saturation
    a. <85% and >95%
    b. 85%-95%
6. To determine growth in relation to infants' median oxygen saturation while in supplemental oxygen
    a. median oxygen saturation > 95%
    b. median oxygen saturation 85% - 95%
    c. median oxygen saturation < 85%
7. To relate incidence of BPD in low and high saturation arms to growth.
8. To determine in-hospital growth velocity/trajectory in low and high saturation arms.
9. To determine long-term growth velocity/trajectory, from hospital discharge to follow up at 18-22 months corrected age in low and high saturation arms.
10. To relate neuro-developmental outcome at 18-22 months corrected age to long-term growth in low and high saturation arms.

Rationale:

The SUPPORT Trial will randomize infants to two ranges of SpO2 in order to test the hypothesis that use of a lower SpO2 range will result in an increase in survival of preterm infants without the occurrence of threshold retinopathy of prematurity and/or the need for surgical intervention. Retrospective cohort data from several units in the U.K., with different oxygen supplementation policies, revealed poorer growth patterns in the preterm infants exposed to higher oxygen saturations for the duration of oxygen exposure (Tin 2001). Conversely, observational data of infants with established BPD show better growth with home oxygen support (Groothius 1987), and two recent RCT of different target saturations in older oxygen-dependent premature infants showed no difference in short or long-term growth outcomes (STOP-ROP 2000, BOOST Trial 2003). There are no RCT data evaluating the short or long-term growth impact of different SpO2 strategies with supplemental oxygen use in a birth cohort of extremely preterm infants. Therefore, this study provides an opportunity for us to obtain critically needed growth information on premature infants who are exposed from birth to different target oxygen saturation strategies.

Background

Improvements in antenatal care, respiratory support and nutrition have contributed to increased survival of ELBW infants. As the number of survivors increase, the long term outcome of these infants becomes more important. Lemons et al described growth failure or weight <10th percentile at 36 weeks postmenstrual age in 97% of ELBW infants surviving to discharge. Some morbidities in adulthood are linked to growth during the early post-natal period (Singhal 2004) and make adequacy of growth in this population of heightened interest.

Instead of following intra-uterine growth curves of age matched fetuses, VLBW infants exhibit wide-spread post-natal growth retardation (Cooke 2004), losing ground during the first weeks of life (Berry 1997). To resume growth post-natally, nutrition is of paramount

importance; however, other factors such as severity of illness and perhaps oxygenation also play a role. Observational studies of infants with BPD showed poor post-natal growth when infants were sent home without oxygen supplementation (Markestad 1981).

Although preterm infants without lung disease attain oxygen saturations >95%, artificial attempts to keep arterial oxygenation at a "physiological" level may not be beneficial to growth, the lung or retina (Tin 2001). Animal studies have shown that newborn mammals (mice, rats, guinea pigs) develop poor growth with chronic hypoxia and that blunted body growth is directly proportional to the profundity of the exposure to chronic hypoxia (Mortola 1990). Chronic hypoxemia has also been suggested as the cause of poor growth in patients with cyanotic congenital heart disease (Dundar 2000). When home oxygen supplementation was discontinued inappropriately by parents in a cohort of VLBW infants with BPD, there was a deceleration in the rate of weight gain, which improved when oxygen supplementation was resumed (Groothius 1987). Hudak et al in 1989 observed that ELBW infants with CLD who went home on oxygen supplementation had good catch-up growth at 19 months. Taken collectively, these data suggest that hypoxic conditions affect growth negatively and supplementing oxygen may improve growth.

The optimal level of oxygen saturation to promote post-natal growth is unknown. Most of the available human data is limited to oxygen supplementation of infants who are oxygen dependent or have BPD. Baraldi et al demonstrated that discharged infants with BPD, who were kept on supplemental oxygen to keep saturations above 94%, had progressive but poor weight gain (stayed below 3rd percentile) at 9 months corrected age follow-up. In infants with BPD whose oxygen supplementation was intentionally discontinued, the subset who exhibited episodes of desaturations below 88-91% had a significant decline in the rate of weight gain as compared to those who maintained saturations above 92% (Moyer-Mileur 1996). Conversely, when two different oxygen saturation control policies (high: 88-98% and low: 70-90%) were retrospectively reviewed in <28 week gestation infants, the infants being cared for in the high oxygen saturation policy units were more likely to weigh less than the 3rd percentile at discharge (45% vs. 17%, Tin 2001). The infants assigned to the high oxygen saturation limits were also more likely to have BPD and ROP.

Recently, the BOOST Trial demonstrated that randomizing infants born <30 weeks gestation who were still on oxygen at 32 weeks postmenstrual age either to standard saturations (91-94%) or to high saturations (95-98%) produced no significant difference in growth at 12 months corrected age. This study, while randomizing infants to two different levels of saturations (conventional and high), only enrolled infants if they were still on oxygen supplementation at 32 weeks PMA and used higher limits than planned by SUPPORT. Our proposal is novel in that randomization to the two oxygen strategies begins at birth and continues for as long as the infants are in supplemental oxygen - by implementing this secondary we will be able to determine the impact of these strategies on short and long-term growth.

Methods:

Anthropometric Measures – at birth, postnatal days 7, 14, 21, and 28 days, 32 w PMA and 36 w PMA or discharge (wt, length, HC)

1. Weight - using standard digital electronic scales (c/o infant's nurse)
2. Length - using the Premie Length Board (average of two values, c/o research staff)

3. Head circumference - using paper measurement tape (average of two values c/o research staff)

Clinical Data-

1. Date when infant regains birth weight
2. Date of first enteral feed
3. Date of full enteral feeds (enteral > 120ml/kg/d)
4. Total number of days on parenteral nutrition
5. 24 h intake 'snapshots' (Parenteral, Enteral) – postnatal days 7, 14, 21, and 28, 32w PMA, 36w PMA or discharge (whichever comes first)
6. Presence of BPD

Intervention Data –

1. Duration of time spent in target saturation ranges of interest (Already part of SUPPORT‡)
2. Median values for unmasked oxygen saturation while still on supplemental oxygen therapy‡
3. Highest daily FiO_2‡
4. Duration of supplemental oxygen exposure‡
5. Documentation of post-discharge oxygen use

Follow Up data –

1. Anthropometric measurements at 18-22months corrected age
2. Neuro-developmental follow up at 18-22 months corrected age

Primary Outcome:

Growth in-hospital and at 18-22 months corrected age and in-hospital growth trajectories in high and low saturation arms.

Sample Size:

Given the importance of using an RCT to establish the impact of different levels of oxygen saturation from birth on short and long term growth, and recognizing the wealth of oxygen saturation data that will be available for analysis combined with the absence of comparable data in the literature, all infants in the SUPPORT Trial should be recruited into this secondary (n=1320). This sample size will be adequate to detect subtle differences in growth between the two groups with adequate ($\geq$80%) power. For example, this sample size will have at least 80% power to detect a difference in means between the two saturation groups of less than 40 g (assuming a mean weight of 1000 g in the control group and a standard deviation of 250 g) using a two group t-test with a 0.05 two-sided significance level.

Statistical Analysis:

Based upon intent-to-treat, differences between treatment arms with respect to continuous outcomes (such as weight, length, etc.) will be assessed by the Student t-test or the Mann-Whitney U-test, depending upon whether the empirical distribution of the data is approximately normal or heavily skewed. Adjusted analyses will be conducted using

linear regression to determine the relationship between measures of oxygen saturation and growth in the presence of covariates and confounders (such as site, gestational age, gender, etc.). Categorical outcomes (such as BPD, growth failure, etc.) will be compared across treatment groups using the chi-square test. Logistic regression models will be developed to determine whether oxygen saturation independently affects growth after correction for confounding variables that also alter growth.

In-hospital growth data will be available over multiple points in time. Outcomes available from this temporal distribution will enable us to perform a longitudinal analysis comparing the trajectories of growth between the two treatment groups. Longitudinal studies are powerful both in terms of explanatory power and statistical efficiency. They are useful in examining whether children in the two different oxygen saturation arms have different developmental trajectories over time. Further, longitudinal studies are statistically more efficient since they acknowledge and account for naturally occurring differences among children, including unmeasured characteristics such as genetic make-up, prenatal exposures, etc.

In order to analyze longitudinal growth data we propose to use hierarchical modeling, where the first stage models growth as a function of time/child's age, and the second stage models this association as a function of each child's treatment status. This flexible modeling formulation allows each child to have its own unique developmental trajectory, which could depend on its treatment status.

Discussion of Anticipated Results

We anticipate a better growth outcome in-hospital and at 18-22 months corrected age in the infants randomized to the lower target saturation range who maintained their median oxygen saturations within study range. We further anticipate that longitudinal analyses will demonstrate that these infants will have a sustained higher trajectory of growth over time compared to infants in the higher target saturation range.

Budget:

Additional nursing time, needed to collect required anthropometric data and other data from chart review at discharge and at follow-up, is estimated to be 1 hour. The cost for the entire cohort (1320 subjects), at $32.00 per nursing hour, would be $42,220. Assuming a 35% mortality for this extremely preterm population (estimated from GDB), 858 subjects could be expected to survive to discharge and estimating time for survivors alone will reduce the budget to $27,456.00.

Subject: SUPPORT GROWTH SECONDARY

HI,
I need a vote from the PI's regarding the SUPPORT GROWTH SECONDARY presented by Dr. Duara last week at the steering committee meeting.

Please indicate your preference:

1. Yes – this needs to go forward without additional funding and should start now
2. Yes – this needs to go forward and we should commit funds from the 2006 budget (this will impact the possibility of other protocols being instituted)
3. No – this needs to wait for the next budget period with reassessment in April 2006
4. No – this should not be done

I have attached the protocol.
Send me your vote by September 30.

Thanks
Rose

Hi Angelita
I hope this baby does well. Thanks for the effort to enroll this family in SUPPORT. You could set a record here!!!

Subject: SUPPORT study baby too small for GDB

Hi Abhik and Scott,
We enrolled a mom who delivered at 24 weeks 3 days into the SUPPORT study (sectioned for PIH) . The baby was IUGR and weighed 370 grams at birth and is not eligible for the Generic Data Base and therefore does not get a GDB Network Number. Don't we need to collect GDB data on this baby and how do we enter the Support Study forms into the data entry system without a Network Number? Please advise.
Thanks
Angelita

Subject: SUPPORT baby

Just a note to let you know that we have officially enrolled our first child in the SUPPORT study (b) (6) (b) (6) -about 2pm. The infant was 24.2wks GA, 594 gms, randomized to the CPAP arm and all went well. We were lucky as the RTT on duty had been the staff person that attended the session in Cincinnati. She said she was pleasantly surprised at how it went, that it went smoother that she had expected, that the baby was down to the nursery within 8 minutes of delivery, and that the child has continued to do well on CPAP. There was a little (okay, more than a little) grumbling from the nursing staff that wanted to take the baby off of CPAP to weigh, etc but that is something we can work on. I will have to admit that we did not cover that as well in our orientation of the staff and that perhaps it would be helpful to them if we weigh all of the various hats, prongs, tubes and provide them with that information on a little card so they can then just subtract those weights to obtain the corrected weight of the infant.

Please let me know if you have any questions.

Nancy P.

Post-natal Growth of Infants Enrolled in the NICHD Neonatal Network Oxygen Saturation (SUPPORT) Study: A Proposed Secondary Study

Cristina Navarrete MD, and Shahnaz Duara MD
University of Miami Miller School of Medicine, Miami, FL.

Abstract:

Post-natal growth restriction is a major problem in preterm infants. Perturbations in oxygenation are recognized to influence post-natal growth; hypoxic conditions can directly impair growth and hyperoxic conditions predispose infants to BPD, which in turn has been linked to poor growth. The NICHD Neonatal Network is conducting a prospective trial of preterm infants randomized to two levels of baseline oxygen saturations. The effect of baseline saturations on pulmonary morbidity and ROP are the primary outcome measures. With respect to post-natal growth, there is a paucity of data relating alterations in baseline oxygen saturation and/or frequent deviations above or below the baseline to growth outcomes. We propose a secondary study to quantify short-term growth velocity in-hospital and long-term growth at 18-22 months of corrected age for infants enrolled in the SUPPORT Trial in relationship to oxygen saturation.

A. Hypothesis to be tested

Primary:

1. Infants in the low oxygen saturation group (85-89%) will have better in-hospital and long-term (18-22 months corrected age) growth.

2. Trajectories of growth in hospital will be better for infants in the low oxygen saturation group.

Secondary:

1. Growth will be greater in infants who spend > 50% of the time with daily median oxygen saturation between 85% -95% while on supplemental oxygen, independent of randomization to low or high oxygen saturation.

2. Infants with BPD will have poorer in-hospital and long-term growth than infants without BPD, independent of the saturation randomization arm.

3. Better long-term growth will be positively related to neuro-developmental outcome, independent of the saturation randomization arm.

B. Specific Aims:

1. To determine anthropometric measurements (wt, HC, length) in infants randomized to low and high oxygen saturation arms, from birth to hospital discharge and again at 18-22 months corrected age.
2. To determine nutritional intake (parenteral and enteral) during hospital stay.
3. To determine the percentage of infants with growth <10 percentile at 36 weeks PMA or discharge, whichever comes first.
4. To determine the percentage of infants with growth <10 percentile at 18-22 months corrected age.
5. To determine growth in relation to the proportion of time spent with oxygen saturation
    a. <85% and >95%
    b. 85%-95%
6. To determine growth in relation to infants' median oxygen saturation while in supplemental oxygen
    a. median oxygen saturation > 95%
    b. median oxygen saturation 85% - 95%
    c. median oxygen saturation < 85%
7. To relate incidence of BPD in low and high saturation arms to growth.
8. To determine in-hospital growth velocity/trajectory in low and high saturation arms.
9. To determine long-term growth velocity/trajectory, from hospital discharge to follow up at 18-22 months corrected age in low and high saturation arms.
10. To relate neuro-developmental outcome at 18-22 months corrected age to long-term growth in low and high saturation arms.

Rationale:

The SUPPORT Trial will randomize infants to two ranges of SpO2 in order to test the hypothesis that use of a lower SpO2 range will result in an increase in survival of preterm infants without the occurrence of threshold retinopathy of prematurity and/or the need for surgical intervention. Retrospective cohort data from several units in the U.K., with different oxygen supplementation policies, revealed poorer growth patterns in the preterm infants exposed to higher oxygen saturations for the duration of oxygen exposure (Tin 2001). Conversely, observational data of infants with established BPD show better growth with home oxygen support (Groothius 1987), and two recent RCT of different target saturations in older oxygen-dependent premature infants showed no difference in short or long-term growth outcomes (STOP-ROP 2000, BOOST Trial 2003). There are no RCT data evaluating the short or long-term growth impact of different SpO2 strategies with supplemental oxygen use in a birth cohort of extremely preterm infants. Therefore, this study provides an opportunity for us to

obtain critically needed growth information on premature infants who are exposed from birth to different target oxygen saturation strategies.

Background

Improvements in antenatal care, respiratory support and nutrition have contributed to increased survival of ELBW infants. As the number of survivors increase, the long term outcome of these infants becomes more important. Lemons et al described growth failure or weight <10th percentile at 36 weeks postmenstrual age in 97% of ELBW infants surviving to discharge. Some morbidities in adulthood are linked to growth during the early post-natal period (Singhal 2004) and make adequacy of growth in this population of heightened interest.

Instead of following intra-uterine growth curves of age matched fetuses, VLBW infants exhibit wide-spread post-natal growth retardation (Cooke 2004), losing ground during the first weeks of life (Berry 1997). To resume growth post-natally, nutrition is of paramount importance; however, other factors such as severity of illness and perhaps oxygenation also play a role. Observational studies of infants with BPD showed poor post-natal growth when infants were sent home without oxygen supplementation (Markestad 1981).

Although preterm infants without lung disease attain oxygen saturations >95%, artificial attempts to keep arterial oxygenation at a "physiological" level may not be beneficial to growth, the lung or retina (Tin 2001). Animal studies have shown that newborn mammals (mice, rats, guinea pigs) develop poor growth with chronic hypoxia and that blunted body growth is directly proportional to the profundity of the exposure to chronic hypoxia (Mortola 1990). Chronic hypoxemia has also been suggested as the cause of poor growth in patients with cyanotic congenital heart disease (Dundar 2000). When home oxygen supplementation was discontinued inappropriately by parents in a cohort of VLBW infants with BPD, there was a deceleration in the rate of weight gain, which improved when oxygen supplementation was resumed (Groothius 1987). Hudak et al in 1989 observed that ELBW infants with CLD who went home on oxygen supplementation had good catch-up growth at 19 months. Taken collectively, these data suggest that hypoxic conditions affect growth negatively and supplementing oxygen may improve growth.

The optimal level of oxygen saturation to promote post-natal growth is unknown. Most of the available human data is limited to oxygen supplementation of infants who are oxygen dependent or have BPD. Baraldi et al demonstrated that discharged infants with BPD, who were kept on supplemental oxygen to keep saturations above 94%, had progressive but poor weight gain (stayed below 3rd percentile) at 9 months corrected age follow-up. In infants with BPD whose oxygen supplementation was intentionally discontinued, the subset who exhibited episodes of desaturations below 88-91% had a significant decline in the rate of weight gain as compared to those who maintained saturations above 92% (Moyer-Mileur 1996). Conversely, when two different oxygen saturation control policies (high: 88-98% and low: 70-90%) were retrospectively reviewed in <28

week gestation infants, the infants being cared for in the high oxygen saturation policy units were more likely to weigh less than the 3rd percentile at discharge (45% vs. 17%, Tin 2001). The infants assigned to the high oxygen saturation limits were also more likely to have BPD and ROP.

Recently, the BOOST Trial demonstrated that randomizing infants born <30 weeks gestation who were still on oxygen at 32 weeks postmenstrual age either to standard saturations (91-94%) or to high saturations (95-98%) produced no significant difference in growth at 12 months corrected age. This study, while randomizing infants to two different levels of saturations (conventional and high), only enrolled infants if they were still on oxygen supplementation at 32 weeks PMA and used higher limits than planned by SUPPORT. Our proposal is novel in that randomization to the two oxygen strategies begins at birth and continues for as long as the infants are in supplemental oxygen - by implementing this secondary we will be able to determine the impact of these strategies on short and long-term growth.

Methods:

Anthropometric Measures – at birth, postnatal days 7, 14, 21, and 28 days, 32 w PMA and 36 w PMA or discharge (wt, length, HC)

1. Weight - using standard digital electronic scales (c/o infant's nurse)
2. Length - using the Premie Length Board (average of two values, c/o research staff)
3. Head circumference - using paper measurement tape (average of c/o research staff)

Clinical Data-

1. Date when infant regains birth weight
2. Date of first enteral feed
3. Date of full enteral feeds (enteral > 120ml/kg/d)
4. Total number of days on parenteral nutrition
5. 24 h intake 'snapshots' (Parenteral, Enteral) – postnatal days 7, 14, 21, and 28, 32w PMA, 36w PMA or discharge (whichever comes first)
6. Presence of BPD

Intervention Data –

1. Duration of time spent in target saturation ranges of interest (Already part of SUPPORT‡)
2. Median values for unmasked oxygen saturation while still on supplemental oxygen therapy‡
3. Highest daily FiO_2‡
4. Duration of supplemental oxygen exposure‡
5. Documentation of post-discharge oxygen use

Follow Up data –

1. Anthropometric measurements at 18-22months corrected age
2. Neuro-developmental follow up at 18-22 months corrected age

Primary Outcome:

Growth in-hospital and at 18-22 months corrected age and in-hospital growth trajectories in high and low saturation arms.

Sample Size:

Given the importance of using an RCT to establish the impact of different levels of oxygen saturation from birth on short and long term growth, and recognizing the wealth of oxygen saturation data that will be available for analysis combined with the absence of comparable data in the literature, all infants in the SUPPORT Trial should be recruited into this secondary (n=1320). This sample size will be adequate to detect subtle differences in growth between the two groups with adequate ($\geq$80%) power. For example, this sample size will have at least 80% power to detect a difference in means between the two saturation groups of less than 40 g (assuming a mean weight of 1000 g in the control group and a standard deviation of 250 g) using a two group t-test with a 0.05 two-sided significance level.

Statistical Analysis:

Based upon intent-to-treat, differences between treatment arms with respect to continuous outcomes (such as weight, length, etc.) will be assessed by the Student t-test or the Mann-Whitney U-test, depending upon whether the empirical distribution of the data is approximately normal or heavily skewed. Adjusted analyses will be conducted using linear regression to determine the relationship between measures of oxygen saturation and growth in the presence of covariates and confounders (such as site, gestational age, gender, etc.). Categorical outcomes (such as BPD, growth failure, etc.) will be compared across treatment groups using the chi-square test. Logistic regression models will be developed to determine whether oxygen saturation independently affects growth after correction for confounding variables that also alter growth.

In-hospital growth data will be available over multiple points in time. Outcomes available from this temporal distribution will enable us to perform a longitudinal analysis comparing the trajectories of growth between the two treatment groups. Longitudinal studies are powerful both in terms of explanatory power and statistical efficiency. They are useful in examining whether children in the two different oxygen saturation arms have different developmental trajectories over time. Further, longitudinal studies are statistically more efficient since they acknowledge and account for naturally occurring differences among children, including unmeasured characteristics such as genetic make-up, prenatal exposures, etc.

In order to analyze longitudinal growth data we propose to use hierarchical modeling, where the first stage models growth as a function of time/child's age, and the second stage models this association as a function of each child's

treatment status. This flexible modeling formulation allows each child to have its own unique developmental trajectory, which could depend on its treatment status.

Discussion of Anticipated Results

We anticipate a better growth outcome in-hospital and at 18-22 months corrected age in the infants randomized to the lower target saturation range who maintained their median oxygen saturations within study range. We further anticipate that longitudinal analyses will demonstrate that these infants will have a sustained higher trajectory of growth over time compared to infants in the higher target saturation range.

Budget:

Additional nursing time, needed to collect required anthropometric data and other data from chart review at discharge and at follow-up, is estimated to be 1 hour. The cost for the entire cohort (1320 subjects), at $32.00 per nursing hour, would be $42,220. Assuming a 35% mortality for this extremely preterm population (estimated from GDB), 858 subjects could be expected to survive to discharge and estimating time for survivors alone will reduce the budget to $27,456.00.

Subject: RE: SUPPORT time in target range

Hi Neil and Wade,

Attached are two documents showing the proportion of time patients are kept

in the target pulse ox ranges at each center. The low and high cases are grouped together. In one document, the numbers are based on all the available pulse ox data. In the other, the numbers are only for days on which we know the babies spent time on supplemental O2. This determination is made using information from form SUPP05. If the baby was intubated/CPAP for >8 hours on a given day and the FiO2 value at 8:00, 16:00 or 23:59 was >.21 or if the baby was on cannula/hood for >8 on that day and FiO2 recorded closest to noon was >.21, then the baby was determined to be on supplemental O2 for that day.

As you will see, we could not identify many records corresponding to days spent on supplemental O2. There are a couple of reasons for this: (1) we have not received forms SUPP05 from some of the centers, (2) we only have information about supplemental O2 for the first 14 days of life, so pulse ox data for days 15 and higher are not included.

Please let me know if you have any questions.

Neil and Wade,

Attached is a document showing the percent of time babies in the SUPPORT trial have been kept in the target SpO2 ranges. Separate percentages were calculated for the low and high SpO2 arms and for each center. Please note that these are the oximeter display values, not the actual SpO2 values. Also, note that the numbers are based on a very small number of babies. The tables include the number of babies and total number of hours of SpO2 data that went into calculating the percentages. The percent of time in each range is the overall percent of time babies at the center were kept in the range, as opposed to the average percent of time each baby was kept in the range. In other words, babies for whom more data were collected (over a longer period of time) are more heavily weighted in the percent calculations. If you have any questions regarding how these numbers were calculated, please let me know.

Hi Folks,
We cannot start using the new RA challenge procedure for the SUPPORT study till we have it approved by our IRB and we need the updated manual (appendix) to do that. My understanding is that there were further revisions to be made to it after the last GDB conference call.

For now we have no choice but to code the infants who have reached 36 weeks and who are on vapotherm by the existing criteria. There have been 4 infants to date.

Thanks
Angelita

Rose,

I agree with Mike that this has been embarassing. We did discuss this somewhat on the last conference call--the delay in SUPPORT. It has been an unusual last few months with my staff out with illnesses (themselves and family) and vacation--and many days I found that I had to cover for three staff members. I had not planned to (b) (6) and delayed the start of Candida and SUPPORT. We are in the midst of interviewing for additional research staff and plan to add another full-time person dedicated to NICHD projects. We are committed to our NRN projects and have been pleased to find that our sites have showed a pride in having a connection to the NICHD, and an increased enthusiasm in participating in neonatal studies (teaching old dogs new tricks sometimes takes a bit of time).

Thank you for always making yourself available to answer our questions and give us your support. I can only hope for "five more years", but realize that our delay in getting started in these trials goes on the negative side of the score board for us. Perhaps we will rebound and be as successful with enrollment with SUPPORT as we have with PCV7.

Rose,

This is embarrassing, but we have been IRB approved for both studies for at least a couple of months. I met with Nancy this morning she assures me that we will begin recruiting for Candida this week and SUPPORT on Monday August 29. I am sorry that we have been slow initiating these studies.

Subject: enrollment

Hi Mike,
On the latest monthly reports, there are no infants enrolled or screened either in the Candida Trial or the

SUPPORT Trial from the Wake Forest site. I confirmed this with the data center. I had thought you had IRB approval and were all set with these two studies. Can you let me know if this is not correct? If you do have IRB approval, let me know why there are infants screened.
Thanks
Rose

Hi,
Dr. Finer has asked that Dr. Edmund Hey receive a copy of the SUPPORT protocol. Dr. Hey is leading the oximetry study in the UK. Since we recently voted to allow Dr. Tarnow-Mordi access, we will also allow Dr. Hey the same access.
Thanks

Date:	Thursday, August 18, 2005 12:20:14 AM

Hi Barbara
Thanks for sharing this with us. At the present time the Network has access to about 250 oximeters and we are shipping from center to center using some depot centers as the need arises. I used your calculation and came up with 225 oximeters, about 25 less than we have at present. I hope these numbers work but I would caution you that the problem we have seen is multiple deliveries where we randomize all to one arm. Thus last night we needed [redacted] oximeters of the same skew for (b) (6) As you are allowing up to 18 hours from birth, this may be a buffer allowing for sharing but I doubt that this will work. In addition you have large distances to cover. We did our own calculations and initially thought that 225 would work and that was our initial supply, but we are not yet certain that when all centers enroll at peak efficiency that we will have enough. I think a 10% loss is acceptable, as we also have to obtain prenatal consent which probably has a greater failure than postnatal consent. We start the oximeter by 1 hour of age.
Lets keep in touch and see how the numbers work. I would guess that we will need up to 300 oximeters by the time we are at full capacity with 16 centers enrolling 1300 infants over 2 years. However, we discontinue the oximeter once the infant is in room air for 3 days and not on any respiratory support which may increase your needs relative to ours. We restart if the infant requires any support or oxygen.
Good luck.
Neil

Rose,

Nancy Newman seemed a bit distraught at the idea of being a transfer center for oximeters, saying she did not have time. If you want to just have her purchase the oximeters and ship them one time to me, I will be the control site for that 10 oximeters as well . Since we all ship Next-Day anyway, it is probably immaterial where we are located.

HI,
We have had a request to share the SUPPORT data collection forms and manual with Dr. William Tarnow-Mordi and the BOOST 2 trial investigators. The reason for this request is to insure that, if meta analyses are done, data are collected from the trials in a similar, if not identical manner. The BOOST 2 trial has obtained funding. Please send me your YES/NO vote by August 22.

Thanks

From: Yvonne Vaucher [mailto:yvaucher@ucsd.edu]
Sent: Friday, August 05, 2005 1:13 PM
To: mgfuller@ucsd.edu; wrich@ucsd.edu; 'Neil Finer'
Subject: RE: Pulmonary follow up secondary to SUPPORT

Martha/Wade: I agree that the data will be more accurately collected in person for our population and that telephone interviews for our population are particularly problematic due to language, suspicion, difficulty connecting. There are differences in scripted telephone vs less formal in-person interviews that might be cause for some statistical concern but I assume that issue has already been addressed by RTI.

My concerns are not so much about the kids who come to clinic, but about those who don't. Attempts at telephone contact for children who don't come to clinic (~ 20%) will be costly in time/effort. We need to be paid substantial extra $ if we do this instead of Rochester. Alternatively we could refer families that are difficult to contact to Rochester for them to pursue. Also contacting the PMD and cajoling the office to provide documentation of respiratory problems will also very be time-consuming and I am betting quite frustrating. The $25 "carrot" will not be persuasive for most providers given the time and effort to do the review and the PMD has no investment in the outcome (unlike the original Tucson docs).This aspect in particular should be done by Rochester. We are already at our limit trying to get kids into clinic. I think I would favor a hybrid approach...we do the questionnaire in clinic. If child does not come to clinic, then Rochester does the calls/recalls. In addition Rochester should be directly responsible for obtaining the medical record review (We could mail the request and ask the PMD to send the results directly to Rochester; Rochester should do the follow-up/ browbeating of the individual PMD offices to get the data. In terms of the medical record review we are an unnecessary middleman....an additional step/place to get things lost or confused.

Yvonne

---

1) Re: questionnaires these are better (still too wordy in my opinion) but an improvement.
2) I would like for us (actually, I guess it will be me since I'm in clinic) to administer the questionnaires. The more I work with our population the more convinced I am that it will be better to do this as part of our routine visits. The draft consent even includes as a benefit the early identification of breathing problems brought to the attention of the doctor.
3) Consent: Wade, do we already have IRB approval for the pulmonary f/u? If not, are you able to take that on? There is a draft consent attached. It seems to be relatively simplistic so it may meet our IRB standards. I am certain that in addition to the consent we will need to use the medical center approved release of records form to get permission to contact the md's for the information. Can that be attached to the consent?

Hi
Dr. Stevens has revised the questionnaires based on the comments from the FU Training meeting. Please review and send comments back by August 11 so this can get started.

Note from Dr. Stevens:
Attached are the revised questionnaires, including scripting that explains how the questions are to be asked and makes administering the questionnaire faster. Our telephone researchers trialed the questionnaires, it takes less than 10 minutes if the child has had only mild symptoms. A child with severe lung symptoms might take 20 minutes.

It is fine to administer the questionnaires in person. The Tucson Study administered them in person to some study participants.

I've also included a model of a Pulmonary Outcome Consent for patients already enrolled in SUPPORT. We'd like to include them in the Pulmonary Outcome data as well. We hope that each center will modify their primary SUPPORT consent to include consent for the Pulmonary Outcome Study (model sent previously).

Thanks

Means ± Standard Deviation

	CPAP N=55	Control N=48
Birth Weight	753 ± 196	799 ± 186
Gestation (weeks)	25 ± 1.3	25 ± 1.2
Apgar @ 1 min	4	4
Apgar @ 5 min	6	6
Apgar @ 10 min	6	6

Percent Intubated in DR by Gestational Age

Conclusions from DR- CPAP Trial

- ✓ ***All Infants < 24 weeks required DR Intubation for resuscitation!***
- ✓ **Early CPAP in the DR is a feasible intervention for infants ≥ 24 weeks**
- ✓ **It is possible to provide CPAP as a randomized intervention in the DR for the ELBW Infant**

SUPPORT Trial

- **Essentially 2 trials conducted simultaneously on the same population of ELBW infants**
- **A Factorial design which ensures that there will be an equal number of infants randomized to each of the 4 possible strategies**
- **Not prospectively powered to evaluate an interaction, but if a large interaction exists, it will be noted**

SUPPORT Trial

Randomized Intervention	Low SpO2 85% to 89%	High SpO2 91 to 95%
Early CPAP With Permissive Ventilation	Early CPAP + Low SpO2	Early CPAP + High SpO2
Control with Prophylactic Surfactant	Control + Low SpO2	Control + High SpO2

PRIMARY HYPOTHESES

- **EARLY CPAP AND PERMISSIVE VENTILATORY STRATEGY WILL INCREASE SURVIVAL OF ELBW INFANTS WITHOUT BPD**

- **LOWER SpO2 (85-89%) WILL INCREASE SURVIVAL WITHOUT SEVERE ROP (THRESHOLD DISEASE OR REQUIRING SURGERY)**

Methods: CPAP/Permissive Ventilatory Strategy

- DR management guidelines
- Intubation criteria
- Extubation criteria
- Re-intubation criteria

SUPPORT Trial: Inclusion Criteria

- **Infants with a minimal gestational age of 24 weeks 0 days to 27 completed weeks (up to 27 6/7ths) by best obstetrical estimate**
- **Infants who will receive full resuscitation as necessary, i.e., no parental request or physician decision to forego resuscitation**
- **Infants whose parents/legal guardians have provided consent for enrollment, or**
- **Infants without known major congenital malformations**

SUPPORT Trial: Exclusion Criteria

- Any infant transported to the center after delivery
- Infants whose parents/legal guardians refuse consent
- Infants born during a time when the research apparatus/study personnel are not available.
- Infants < 24 weeks 0 days or $\geq$ 28 weeks 0 days, completed weeks of gestation

Ventilation Criteria

- **In effect for 14 days for all study infants**
- **CPAP may be discontinued when in room air > 1 hour**
- **May be restarted at any time in either group**
- **Nasal SIMV to be used *only* after initial intubation**

Methods: Oxygen Saturation Strategy

Birth – Admit to NICU
Placed on Study Pulse Oximeter < 2 hours

SpO_2 – 85% - 89% **SpO_2 – 91% - 95%**

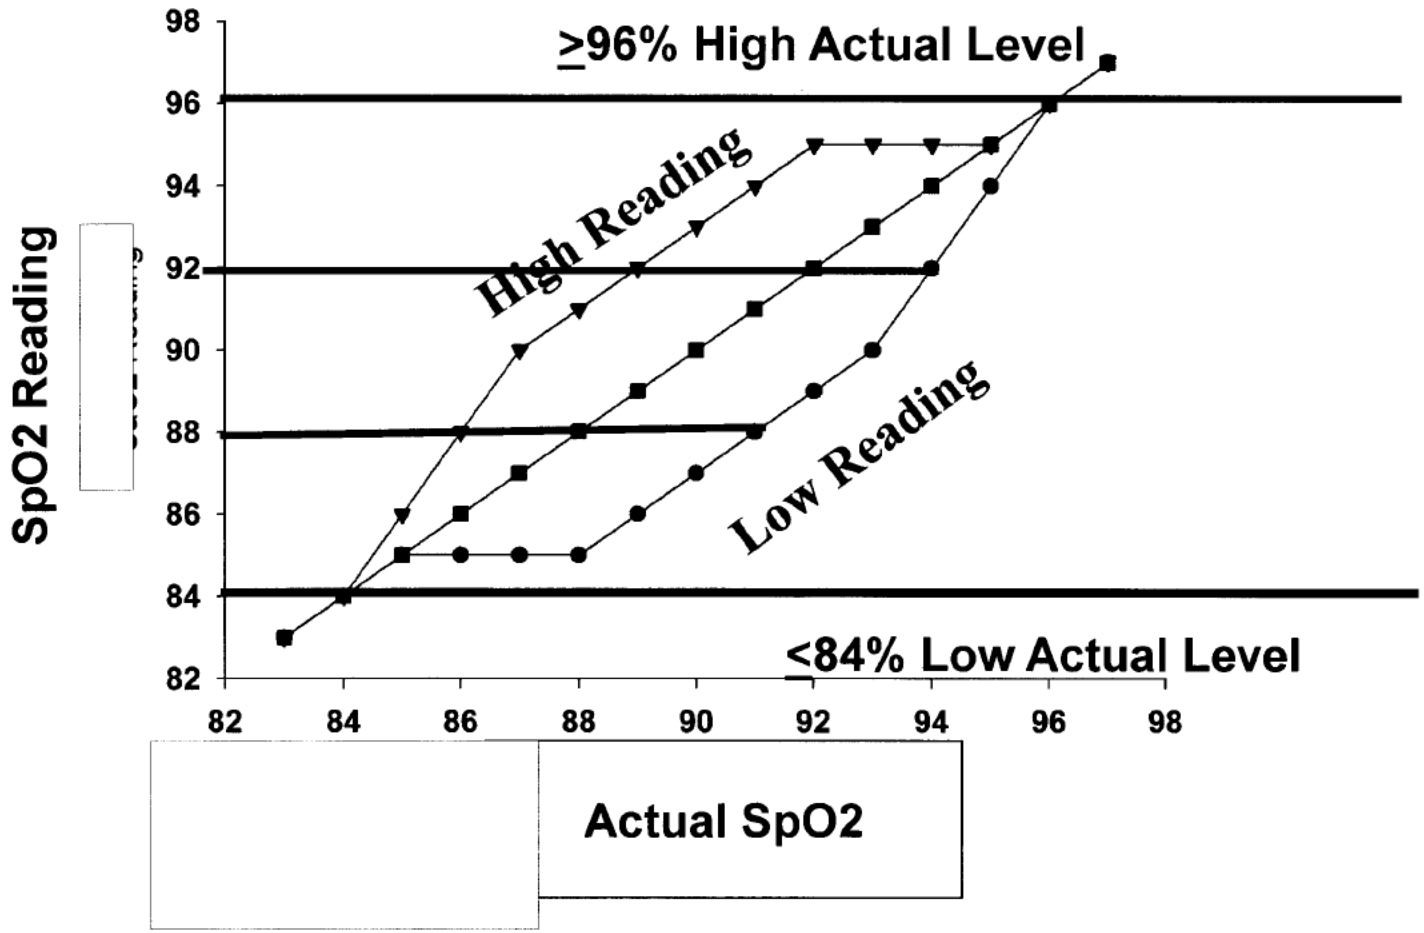
Maintain till off ventilatory support and oxygen

RANDOMIZATION	Displayed Target Range	Actual Range
Low SpO_2 range group	88-92%	85-89%
High SpO_2 range group	88-92%	91-95%

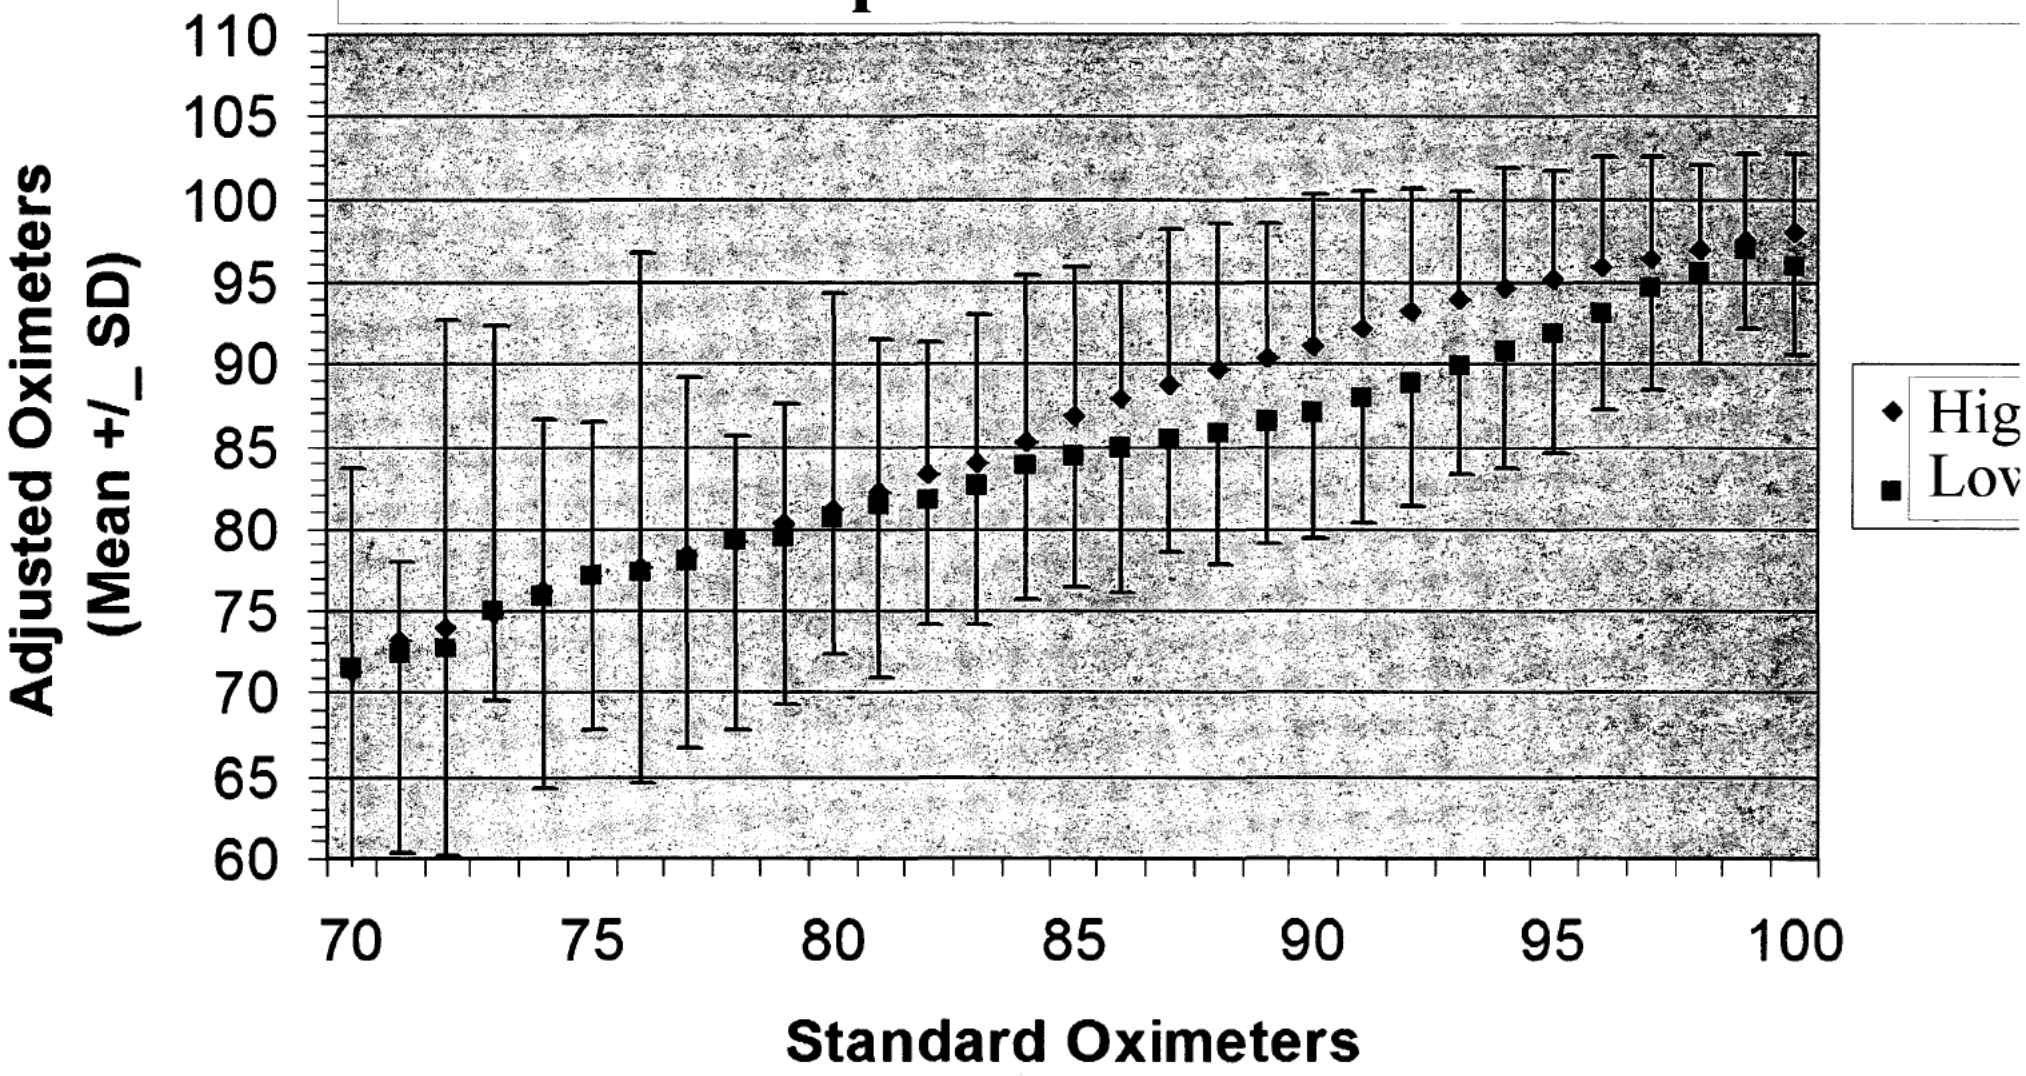
Pulse Oximetry Protocol

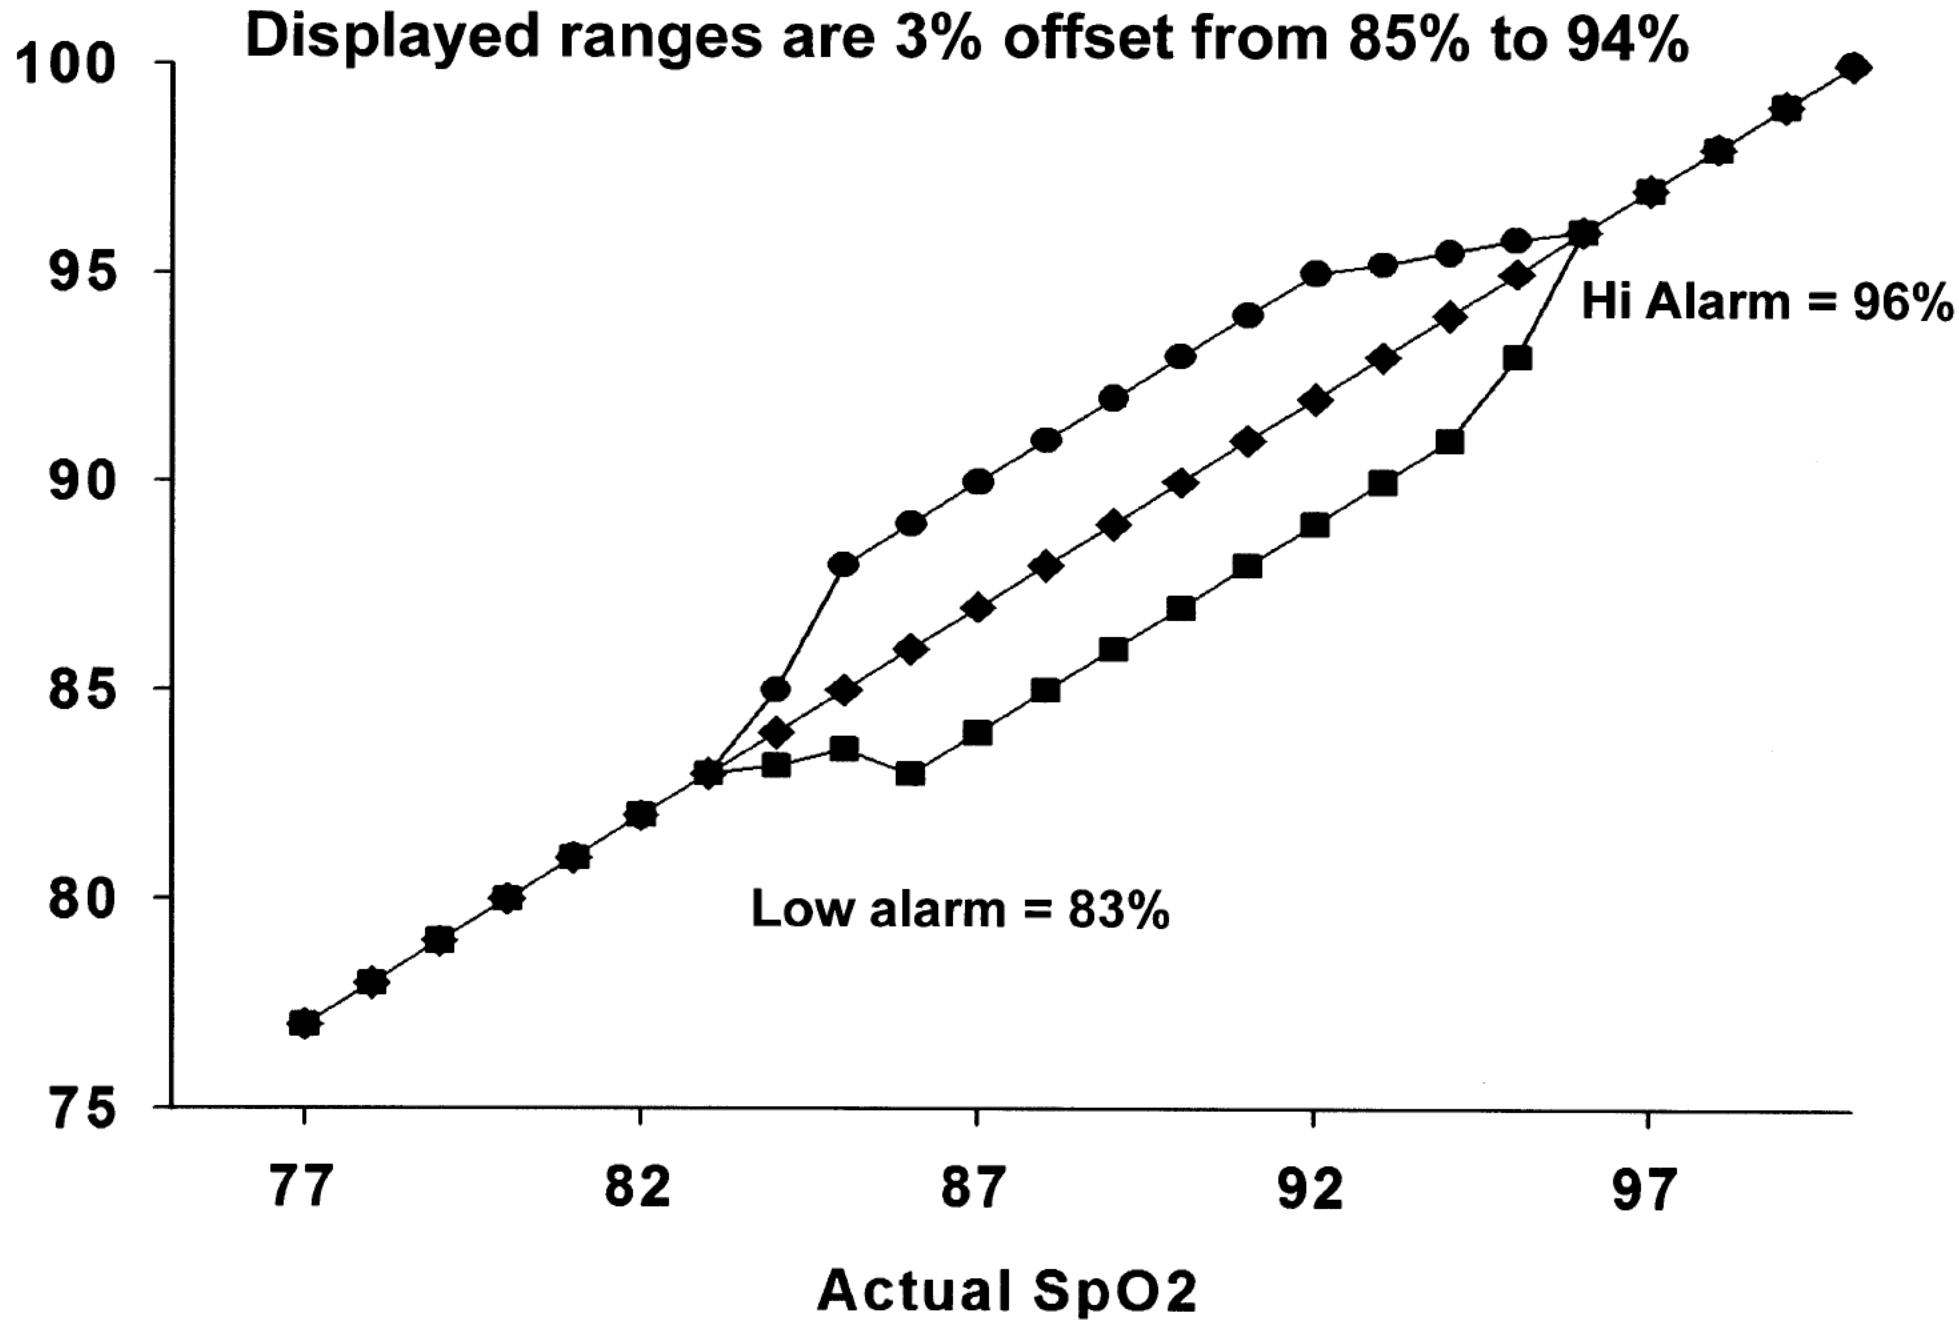
- **LOW RANGE: TARGET SpO2 85-89%**
- **HIGH RANGE: TARGET SpO2 91-95%**
- **STUDY PULSE OXIMETERS (PO) WILL BE SUPPLIED TO PARTICIPATING SITE**
- **STUDY PO'S READING NOT THE ACTUAL SpO2 for READINGS BETWEEN 85% TO 95% FOR BLINDING**

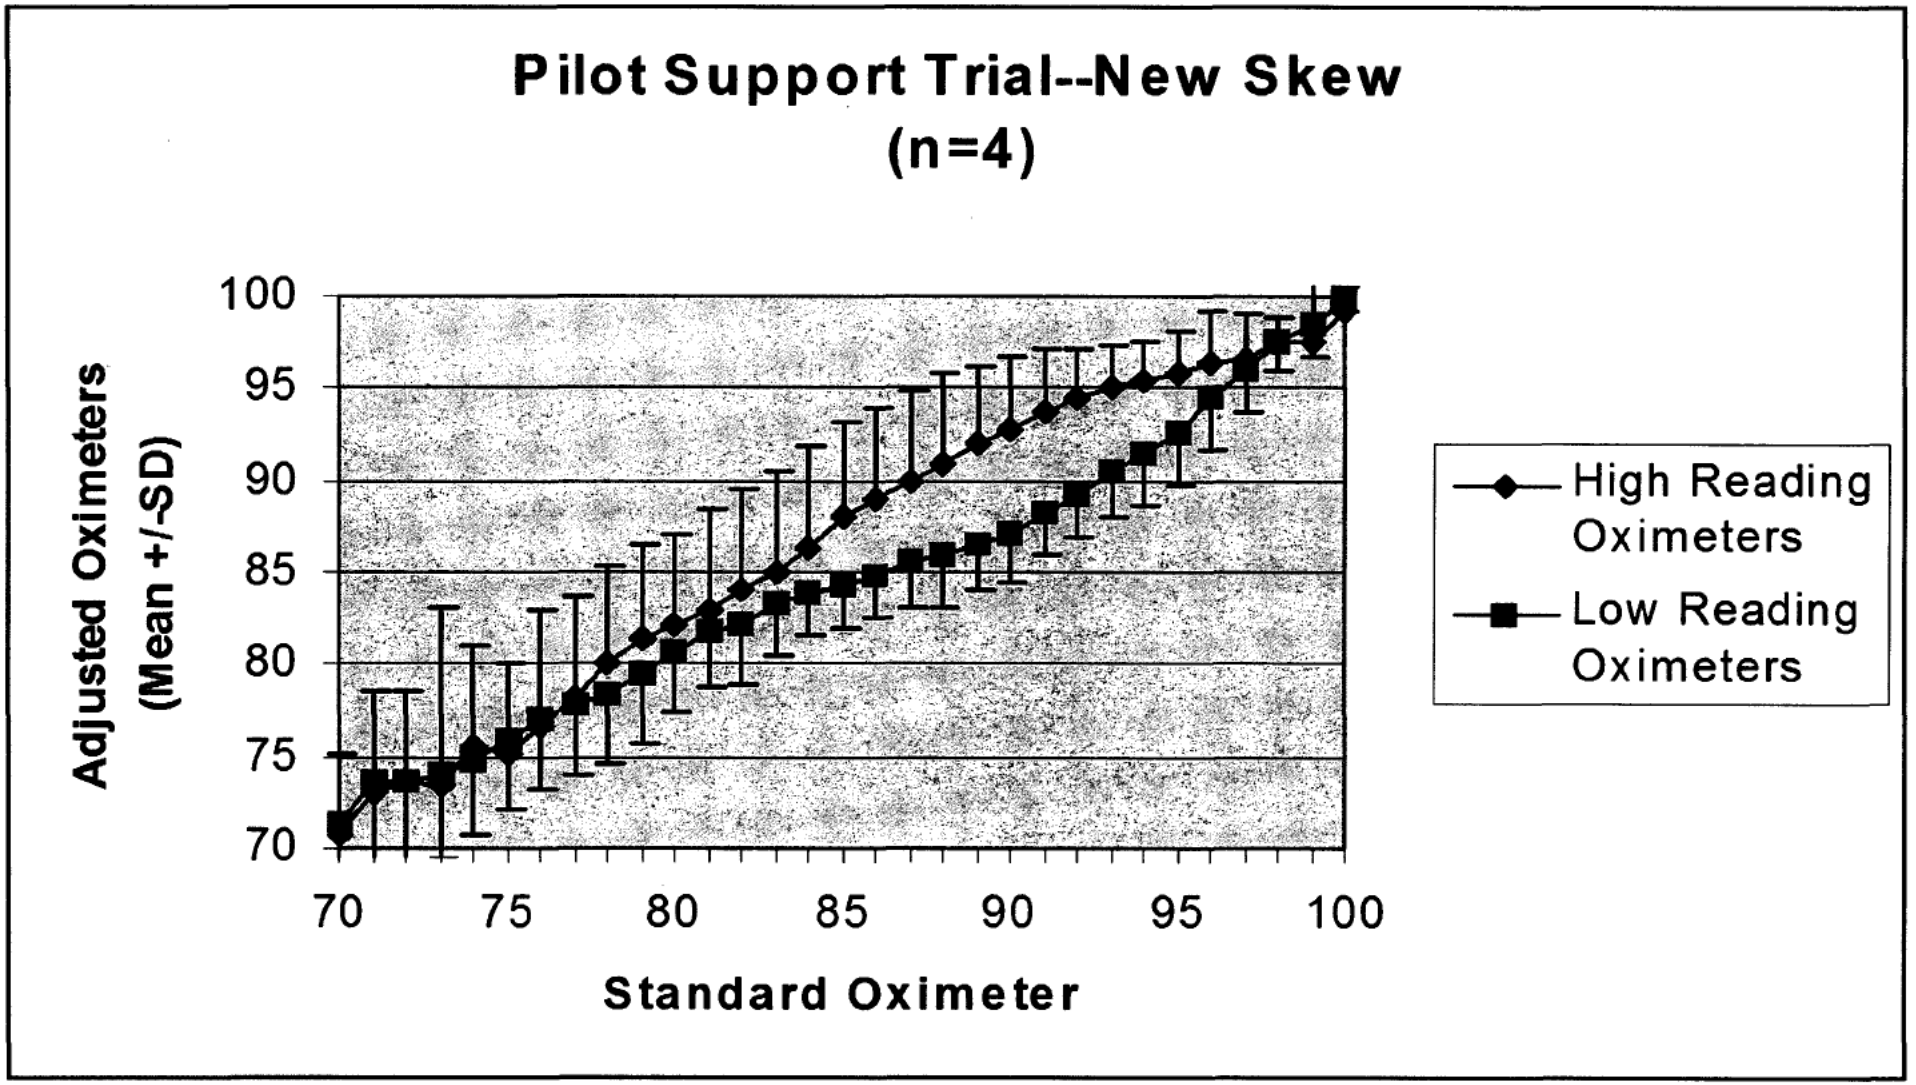
Plot of Actual versus Displayed SpO2



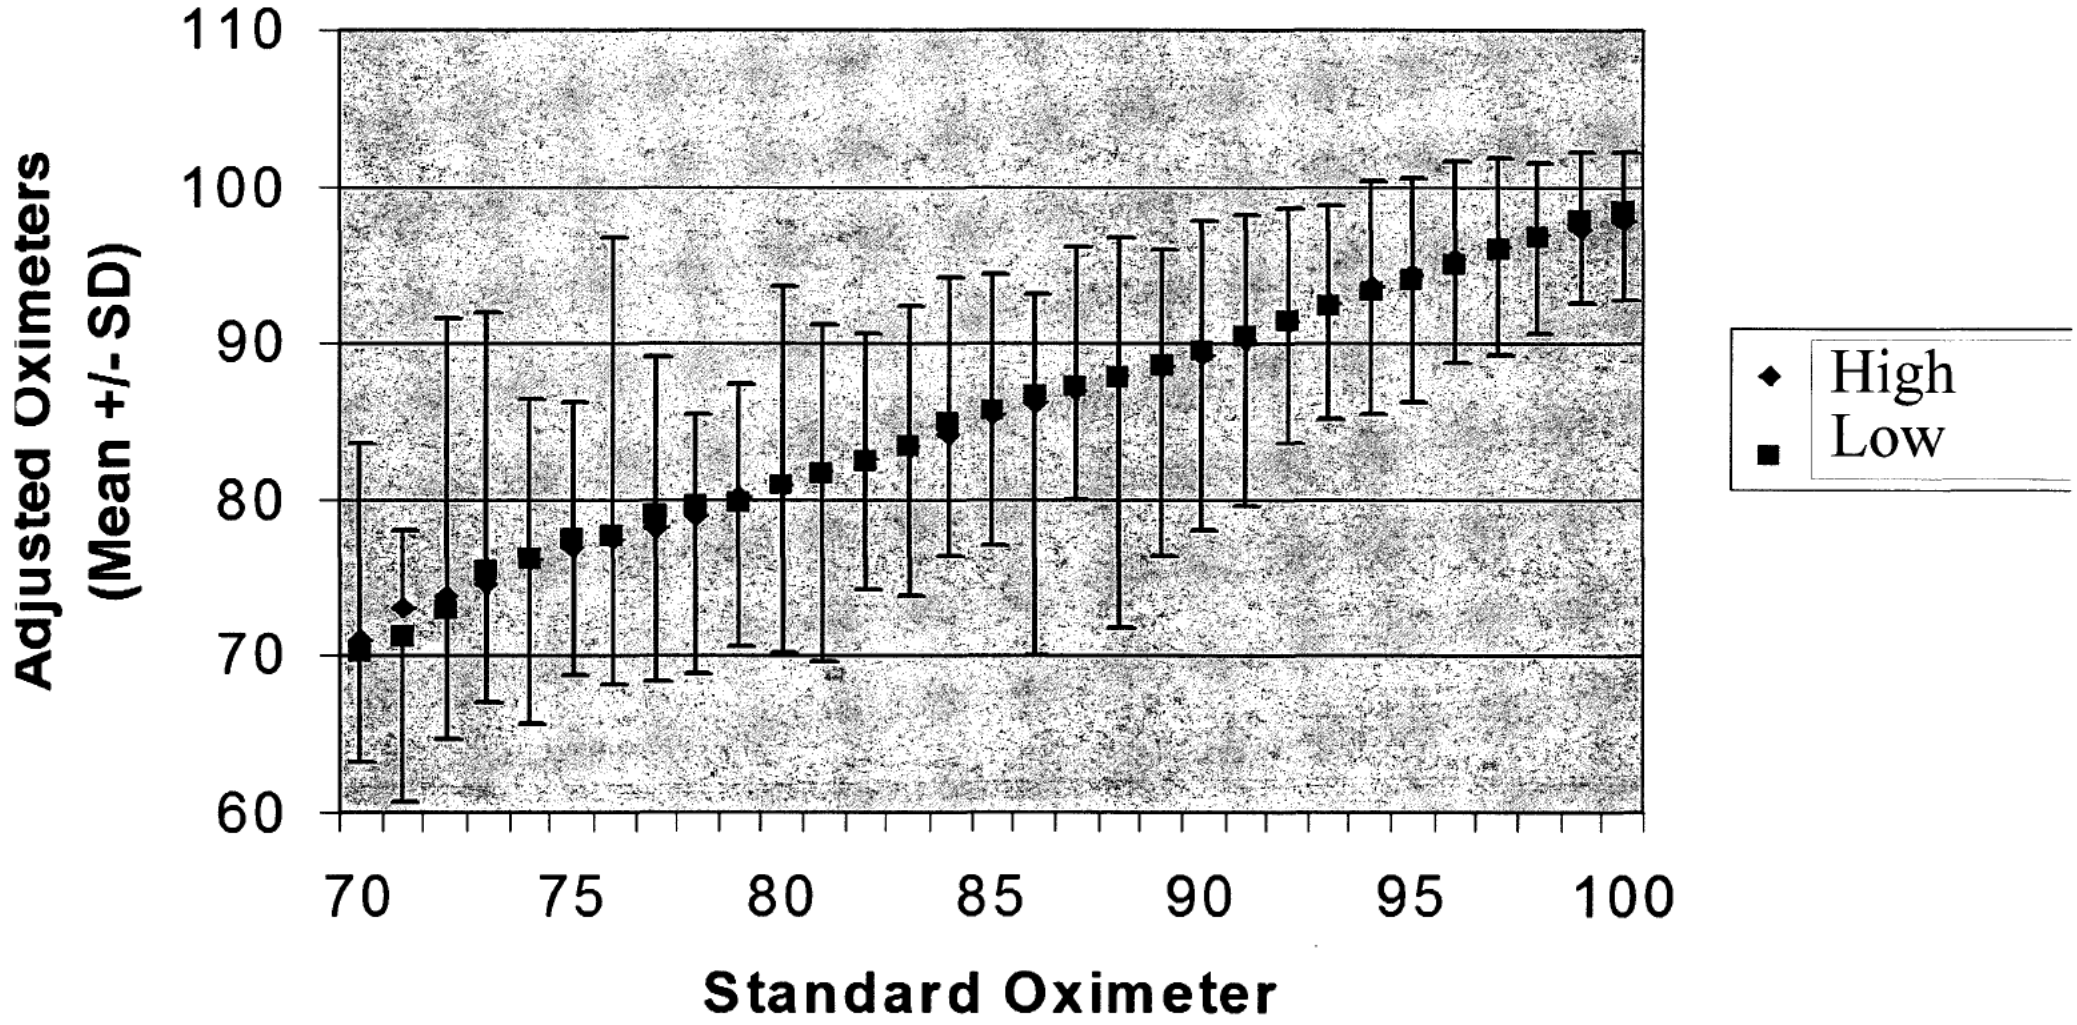
Comparison of High reading versus Low reading Oximeters Compared to a Standard Oximeter







Comparison of High reading versus Low reading Oximeters Corrected to Standard Readings



Pulse Oximetry Protocol

- **BOTH GROUPS WILL MAINTAIN DISPLAYED SATURATION AT 88-92%**
- **ALARMS FOR BOTH GROUPS WILL BE:**

  LOW – 85% HIGH - 95%

  (***Note Masimo alarms at actual limit set point, not one below*****)**
- **SPO2 READINGS BELOW 85% AND ABOVE 95% WILL BE ACTUAL, NOT ALTERED**

OXYGENATION PROTOCOL-CONT'D

- **STUDY PO WILL REMAIN WITH INFANT UNTIL OFF OXYGEN (for 3 days) or INFANT 36 WEEKS PCA whichever is sooner**
- **SpO2 FROM STUDY PO WILL BE DOWNLOADED TO RTI ONCE PER MONTH - every 2 WEEKS DURING STUDY**
- **This will contain 1 data point for SpO2 and heart rate for every 10 seconds of this 1 month interval**

Sample Size

- **Postulating a 10% difference in primary outcome a sample size of 1310 infants will provide for 80% power for the primary as well as NDI/Mortality (Secondary Outcome)**
- **This includes a 17% attrition factor**

SUPPORT – Current Status

- ✓ Enrollment now almost 100 infants
- ✓ We have downloaded about oximeters with 2-4 weeks of data
- ✓ We are within the large target zone of 85% to 95% approximately 55% to 60% of the time
- ✓ This is the zone with the altered SpO2 values

SUPPORT – Current Status

- Downloads better done every 14 days.
- After 28 days you start to loose data!!
- Few issues with respiratory support protocols
- Oximeters – some increased alarms
- This depends on type and settings of oximeters that were previously used.

Oximeter Information
SUPPORT Trial July 2005

- **At the present time based on the available downloads representing over 7000 hours of data we are in the range of 85% to 95% approximately 60% of the time for infants requiring oxygen, and 47% of the time for all infants irrespective of FiO2**

---

> Hi Wally
I'm sending this from Kinkos as I cannot get an email connection that will allow messages.
Here is the presentation. It is larger than I would present, and needs cutting.
Rose also asked that I talk a little about oximeters, and thus the last slides.
I am still going to try to come but will probably have to leave early, so having you there would be great.
Please modify as you see fit, and I will also try to improve.
Many thanks Wally
I'm sorry to have had to burden you with this, and I also think that you should be at this meeting. The oxygen side of this trial was your idea!!
Be well
Neil

Hi Rose: that would be helpful. I have a full talk on the subject but
> includes very few slides specific to SUPPORT.

SUPPORT TRIAL

Rationale
Evidence
Protocol

Evidence for Efficacy of CPAP

- Gregory et al (NEJM 1971;284:1330) demonstrated that CPAP improved oxygenation in infants < 1500 gm with RDS
- Rhodes et al (Pediatr 1973;52:17) reported increase survival with face mask CPAP
- CPAP improves FRC and premature infants without adequate FRC are more likely to develop HMD (Upton et al, Arch Dis Child 1991;66:39)
- The use of CPAP decreases mortality in the presurfactant era (Ho et al Cochrane LibraryCLIB Issue #3 2002)

Evidence for Efficacy of CPAP: Population – European VLBW Cohort Studies

- Jonsson et al (Acta Pediatr 1997;419:4) reported experience from Stockholm from 1988 – 1993 and use of higher $PaCO_2$ 51% treated with early CPAP < 30 min usually, only 1/3 required intubation

✓ Almost all infants < 24 weeks required intubation

- Gitterman et al (Eur J Pediatr 1997;156:384) reported that CPAP usually within 15 min of birth, reduced the need for intubation mortality, and LOS
- Poets et al (Pediatr 1996;98:24) reported ⇩ ventilation, without increased BPD, IVH or PVL in Germany from 1992-1994

Evidence for Efficacy of CPAP: Last Pre-Surfactant Prospective Trial Han et al Early Human Dev 1987;15:21

- Compared early CPAP (up to 2hours after birth)
- ☹No maternal Antenatal Steroids
- ☹CPAP associated with worse oxygenation
- ✘ There is no Post-Surfactant Antenatal Steroid Era prospective RCT comparing DR/Early Surfactant to Surfactant
- ✘ Current Cochrane Review on Prophylactic CPAP concludes that a multicentered RCT comparing prophylactic CPAP with standardized care was needed! (Subramanian et al Cochrane Library Issue4 2003)

Origins of Chronic Lung Disease

- **Review of number of units demonstrated that the unit which used least ventilation, allowed permissive hypercarbia and used initial Nasal CPAP had lowest BPD rates (Columbia)**
- **This unit did not use muscle paralysis**
- **Recently reported low BPD rate = 3/81, (4.7%)**
- **50% survival without BPD for infants 500-750 gm**

Avery et al, Pediatr 1987:79:26

Interhospital Variation of Chronic Lung Disease:
Van Marter et al Pediatr 2000;105:1194

- **Compared early ventilatory practices for VLBW infants at 2 Boston Hospitals (341 infants) with Columbia (100 infants) born from 1991 to 1993**
- **They evaluated use of mechanical ventilation for days 1-3, and 4-7**

❁ ***CLD (O_2 at 36 weeks) was 4% (Babies) vs 22%(Boston)***

❁ **No differences in IVH, PVL, NEC, ROP, or mortality (9% vs 10%)**

Interhospital Variation of Chronic Lung Disease:
Van Marter et al Pediatr 2000;105:1194

Other practices: Babies vs Boston

- ✓ **Surfactant 10% vs 45% more often in CLD, 23% vs 65%**
- ✓ ***CPAP used primarily at Babies 63% vs 11%***
- ✓ ***Mechanical Ventilation as primary 29% vs 75%***
- ✓ **Infants with CLD more likely to receive Mechanical Ventilation 77% vs 42%**
- ✓ **Duration of Mechanical Ventilation 13 days vs 27 days**
- ✓ **$PaCO_2$ higher at Babies**

Mechanical Ventilation and Chronic Lung Disease:
Van Marter et al Pediatr 2000;105:1194

- **Overall Odds Ratio for the development of CLD was related to need for Mechanical Ventilation**
  - **on day of birth - OR = 13.4**
  - **Days 1 - 3 - OR = 9.6**
  - **Days 4 -7 -OR = 6.3**
  - **Maximum PIP of > 25 cmH_2O at birth, or > 20 cmH_2O at 1 -3 days increases risk for CLD**
  - ***Message: If you don't intubate, the babies do better!!!***
  - ***Oh by the way, this is all retrospective information!!!***

Mechanical Ventilation and Chronic Lung Disease:

Serenius et al Acta Paediatrica. 2004; 93(8):1090-1097

- **Other studies have reported association between duration of ventilation and BPD/CLD**
- **BPD was associated with duration of mechanical ventilation (OR 2.71 per 1-wk increment in duration; 95% CI 1.76-4.18)**
- **Other morbidities associated with ventilation**
- **Severe IVH or PVL was associated with duration of mechanical ventilation (OR 1.53 per 1-wk increment in duration; 95% CI 1.01-2.33)**

Nasal CPAP and Early Surfactant for < 30 wk Infants:

Verder et al, Pediatr 1999;103(2).

- 11 Neonatal Units in Denmark from April 1995 to Jan 1997
- Previous study (NEJM 1994;331:1051) showed benefit for early CPAP (not DR) followed by intub + Surf + extubation
- Infants < 30 wks, + RDS, a/APO_2 was .35-.22 on CPAP $\geq$ 6 cmH_2O
- <u>Treated with early CPAP and given Surfactant</u>
- Randomized to :early Curosurf vs later when a/APO_2 < .21-.15
- Infants intubated for Curosurf 2.5ml/kg in 2 doses,

  then extubated, usually within 10 minutes!!!

Verder et al, Pediatr 1999;103(2).

Results: BW=950gm vs 935, Gest=27 vs 28, Nasal CPAP started at median of 17 minutes

➔Randomization at 4.3 hours

➔Early Rx rec'd Surfactant at 5.2 hrs vs 9.9 hrs for late group

➔Only 4 infants could not be extubated after Surfactant instillation

➔MVent/Death = 21% vs 63%, p=0.0013 by logistic regression

➔Death = 9% for Early Rx vs 26% for late Rx

Early CPAP and Surfactant
Verder et al, *Pediatr 1999;103(2).*

- **This was a trial of early not DR CPAP**
- **Also tested surfactant at approximately 4 hours – this is neither prophylactic nor early**
- **Compared earlier vs later rescue surfactant**
- **Could initially extubate all but 4 infants, 2 in each group**
- **6 early and 12 late treated infants required ventilation**

Evidence for Efficacy of DR CPAP: Lindner et al, Pediatr 1999;103:961

- Evaluated prolonged inflation (20-25 cm H2O for 15 secs) followed by CPAP
- Accepted high PaCO2 >70 torr and FiO2 > .6
- Reported a reduction in intubation from 84% in 1994 to 40% in 1996
- No difference in mortality, IVH,BPD and no airleaks on admission to NICU

Sustained Inflations: Do they work?

Lindner et al, Acta Pediatr 2005;94:303

- ✓ **Compared sustained pressure-controlled inflation (15 s) or to intermittent mandatory ventilation @ 60 bpm, given by a nasopharyngeal tube**
- ✓ **The inflation pressure or peak inspiratory pressure increased stepwise (20-25-30 cm H2O) according to the response of heart rate and oxygenation.**
- ✓ **Endotracheal intubation and mechanical ventilation occurred in 61% and 70%**
- ✘ **The rates of mortality severe IVH and CLD not different**

Evidence for Early CPAP: Recent Cohort Studies

- De Klerk and de Klerk (J Pediatr Child Health) 2001;37:161) used CPAP within 10 minutes of birth for infants 1000-1500 gm
- Reported decreased intubation, surfactant use, and ventilation duration and oxygen at 28 days.

Early CPAP in the ELBW Infant

Narendran et al, J Perinatol 2003;23:195

- **Evaluated infants 401-1000 gm and compared historical cohort N=92, with Bubble CPAP initiated in DR, N=79**
- **Gest = 26 weeks, BW = 760 gm**
- **Reported decreases for:**

✓ **DR Intubations - 60% versus 32%**

✓ **Duration of Mech Ventilation – 28 versus 13**

✓ **Use of Post Natal Steroids – 42% versus 14%**

Evidence for Early CPAP:

Thomson et al, Ped Res 2002;45:321A

- **Thomson et al, 237 27-29 week infants - 4 arms – CPAP + Rescue surf, Surf followed by Surf, Early IPPV + Surf, Conventional Management**
- **CPAP began < 6 hours in 76-79% - not DR, not really early**
- ✗ **No differences for CLD**
- **These are most recent studies**

Current Evidence for Early CPAP:

Sandri et al, Arch Dis Child 2004;89:F394-98

- **230 infants 28 to 31 weeks**
- **Randomized to early CPAP < 30 min Mean age = 19min**

  or
- **Rescue CPAP – required FiO2 > .40 for > 30 min for SpO2 93% to 96%**
- **CPAP given with a flow driver 4-6 cm H20**
- **All infants who required > .40 FiO2 on CPAP, and had X-ray compatible with RDS were intubated for surfactant, and then extubated**
- **MVent for FiO2>.40, PaCO2 > 70 with pH < 7.2,or Apnea**

Current Evidence for Early CPAP:

Sandri et al, Arch Dis Child 2004;89:F394-98

- ✓ **Well matched, 115 /gp GA = 30 wks, BW = 1350gm**
- ✓ **Need for Surfactant = 22.6% vs 21.7%**
- ✓ **Need for MVent = 12.2% in both groups**
- ✓ **66/115 Rescue CPAP actually received CPAP at 108 min**
- ✓ **CLD rates (Oxygen at 36 wks) 1.7% vs 0.9%**

- ✓ **SUPPORT will enroll only infants < 28 weeks – None of the above!!**

Early CPAP vs Mechanical Ventilation Recent Trials

- In a study of infants < 28 wks in France,
- 40 received DR CPAP, 20 (50%) subsequently intubated (Boubred et al PAS 2004)
- Dani et al, (Pediatr 2004;113:E560)
- 27 infants < 6 hrs age, < 30 wks on CPAP (started at 35 min) and FiO2 > .3
- Intubated for curosurf, then randomized to CPAP within 5 min (13) vs MVent (14)
- CPAP infants req'd less ventil, oxygen and surfactant and had shorter LOS.

Early CPAP as Support for ELBW "Columbia Approach, A Sirens Song?"

- **We have been seduced into believing that we can avoid intubating ELBW infants by observations presented by many about a few who never published anything prospective about their own practice!!**
- **Much speculation that infants < 700 gm can be managed without intubation**
- **This approach has *Never* been shown to produce good outcomes by any prospective trial**
- **Most current studies have excluded infants < 25 weeks**

DR CPAP Trial NICHD Neonatal Network, Pediatrics, 2004;114:651-7

- **The Network (5 Centers) evaluated a prospective protocol which compared CPAP started at delivery versus the usual approach without DR CPAP**
- ***No infant could be intubated exclusively for surfactant in the DR***
- **All Infants were 28 weeks or less**
- **Intubated and received surfactant in NICU for minimal criteria:**

FiO2 > 0.3 to maintain SaO_2 > 90% or PaO_2 > 45 torr

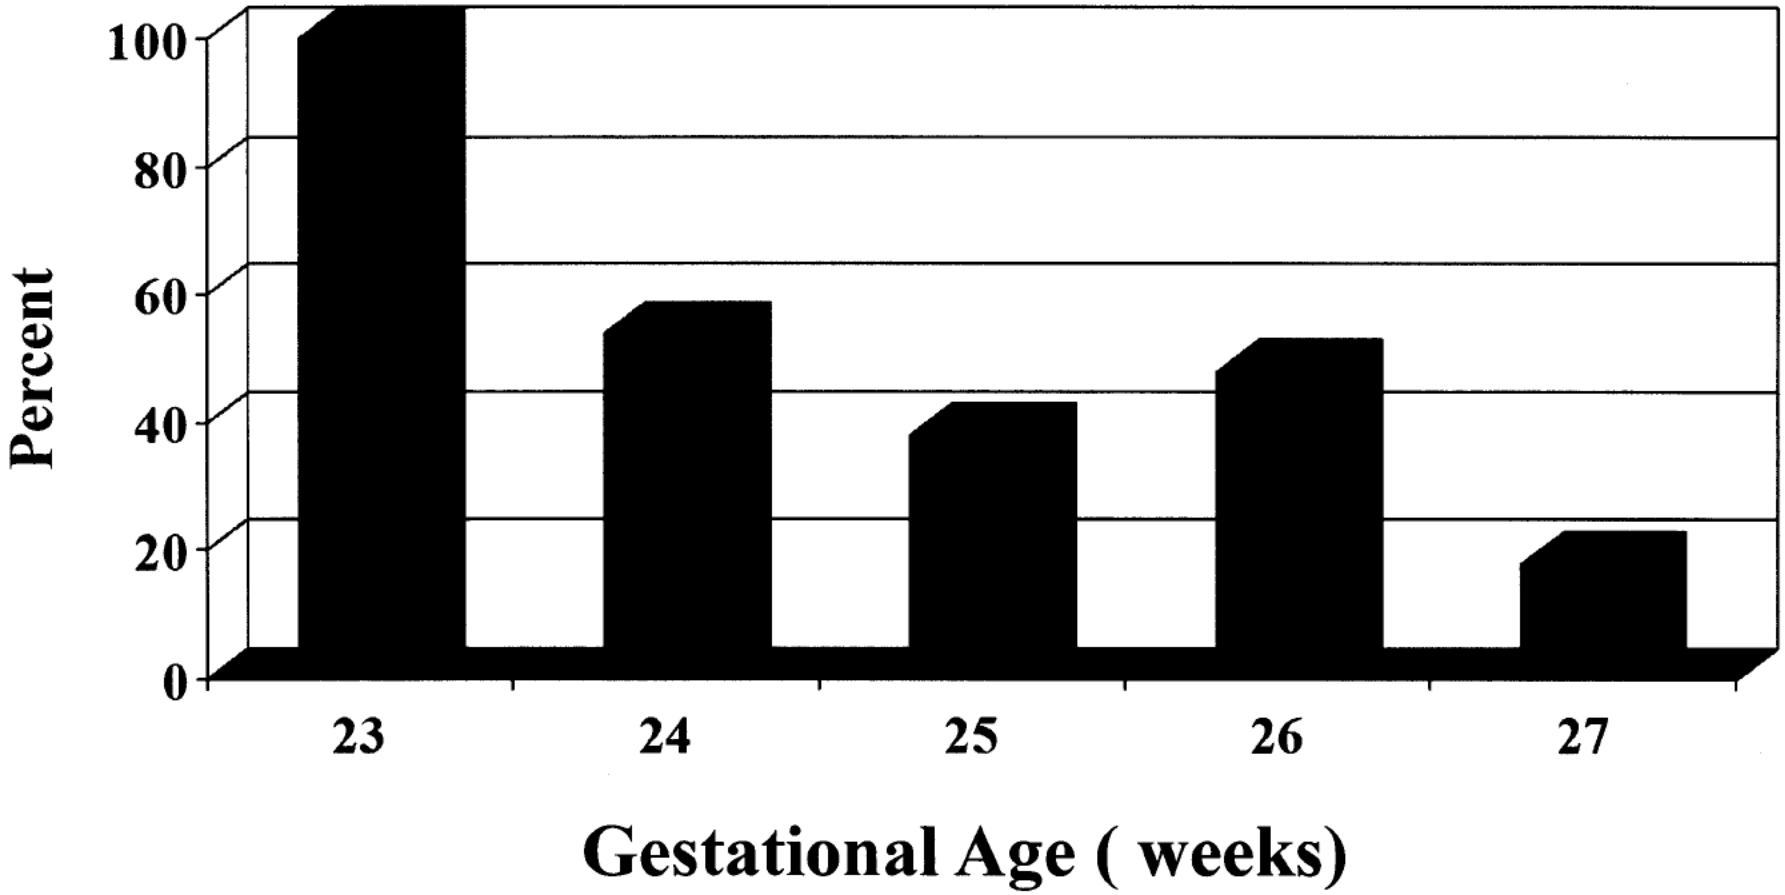
Arterial $PaCO_2$ > 55-60 with pH < 7.25

Apnea requiring bag and mask ventilation

Patient Population
Means ± Standard Deviation

	CPAP N=55	Control N=48
Birth Weight	753 ± 196	799 ± 186
Gestation (weeks)	25 ± 1.3	25 ± 1.2
Apgar @ 1 min	4	4
Apgar @ 5 min	6	6
Apgar @ 10 min	6	6

Percent Intubated in DR by Gestational Age



Conclusions from DR- CPAP Trial

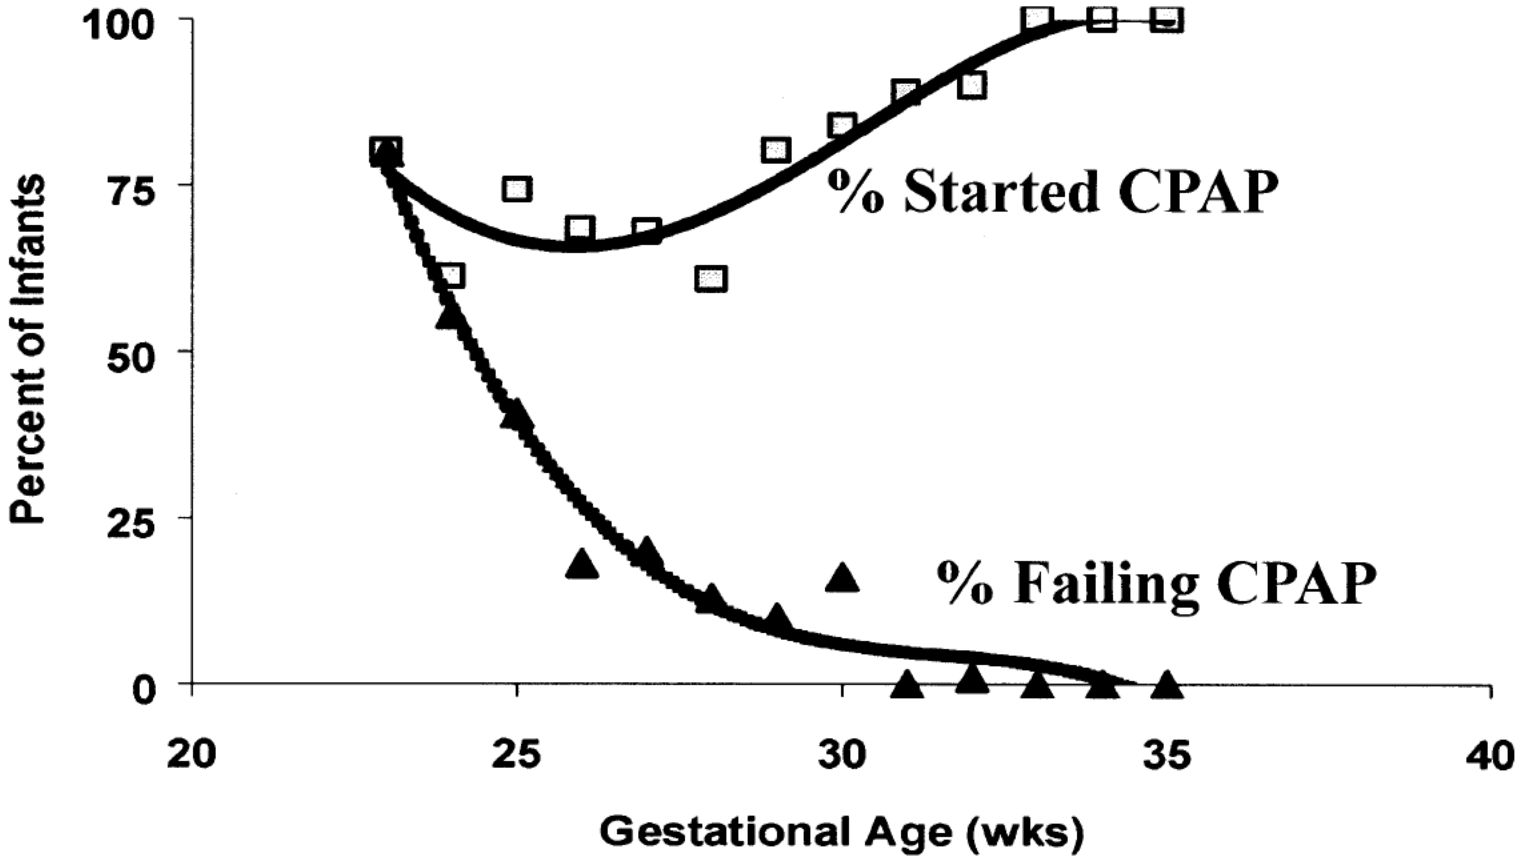
- ✓ ***All Infants < 24 weeks required DR Intubation for resuscitation!***
- ✓ **Early CPAP in the DR is a feasible intervention for infants > 24 weeks and > 500 gm**
- ✓ **It is possible to provide CPAP as a randomized intervention in the DR for the ELBW Infant**

DR use of CPAP for ELBW Infant

Aly et al, Pediatrics. 2005; 115(6):1660-1665

- **Retrospectively evaluated outcomes of VLBW infants treated with early CPAP**
- **Reported that only 10% of infants < 24 weeks could be managed with CPAP alone for > 48 hours**
- **At 25 weeks this improved to 45%**

ENCPAP implementation and failure rates at different GAs



Aly, H. et al. Pediatrics 2005;115:1660-1665

PEDIATRICS

CPAP vs Mechanical Ventilation from Birth Beneficial Effects: Animal Studies

- **CPAP from birth in preterm lambs produces gas exchange similar to or better than mechanical ventilation for 72 hours (Null et al, PAS May 2004)**
- **Preterm lambs treated with CPAP from birth at 2 hours had lungs with greater volumes and lesser neutrophils and hydrogen peroxide than lambs ventilated from birth (Jobe et al, Ped Res 2002:52:387)**

Potential Benefits of Early CPAP Avoid Volutrauma and Hypocarbia

Bjorklund et al, Pediatric Research. 1997 ;42(3):

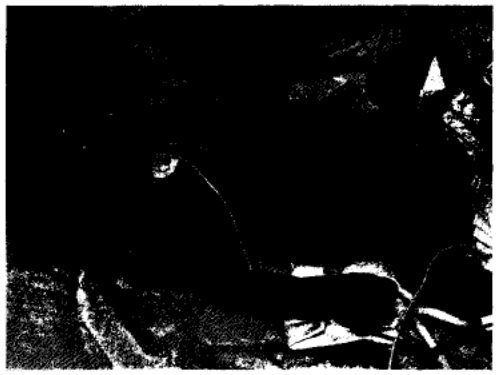
- ✓ **Five pairs of lamb siblings were delivered by cesarean section at 127-128 d of gestation. One lamb in each pair was randomly selected to receive six manual inflations of 35-40 mL/kg prior to surfactant Rx**
- ✘ **Large breaths inhibited surfactant induced increase in compliance and lung volume, and caused more lung injury**
- ✘ **"a few inflations with volumes that are probably harmless in other circumstances might, when forced into the surfactant-deficient lung immediately at birth, compromise the effect of subsequent surfactant rescue treatment."**

What Type of CPAP- Does it Matter?

- **No data to date suggests that one form of CPAP is clinically better than another – Bubble vs Conventional**
- **Variable flow CPAP associated with lower work of breathing and improved compliance, but no effect on FRC and no clinical advantages detected (Pandit et al, Pediatr 2001, Courtney et al, Pediatr 2001, PAS 2004, Stefanscu et al Pediatr 2003, McEvoy et al PAS 2004)**
- **High Frequency CPAP used in 132 day old lambs for 72 hours compared with CMV resulted in better oxygenation over time, with no significant differences in $PaCO_2$ (Null et al, PAS May 2004)**

How Much CPAP??
Animal and Infant Studies

- ✓ CPAP of 8 cmH_2O vs 5 cm H_2O for 6 hours produces better oxygenation than Mechanical ventilation and improves fluid clearance (Mulrooney et al PAS, May 2004)
- ✓ Increasing CPAP improves oxygenation but > 8 cm H_2O may increase air leaks (Probyn et al, Ped Res In Press)
- ✓ Increasing CPAP increases lung volume in preterms, more so with variable flow CPAP (Pandit et al Pediatr 2001)



Most evidence for the beneficial effects of CPAP were described before the introduction of Surfactant

Little is known about the interaction between prophylactic or rescue CPAP and prophylactic or rescue Surfactant

Surfactant versus CPAP

- **The current dilemma is that there is an increasing interest in using early CPAP but the best available evidence indicates that intubation and prophylactic/early surfactant produces the best outcomes**
- **Unfortunately, there are no prospective randomized trials comparing these approaches, especially in the ELBW Infant!!**

CPAP Physiologic Effects May Offset Surfactant Benefit!!

- ☑ Decreases the work of breathing,
- ☑ Establishes and maintain an adequate functional residual capacity,
- ☑ Stabilizes air space, and promotes the release of surfactant stores.
- ☑ Avoiding endotracheal intubation is of benefit for mucociliary transport and humidification of inspired air, as well as decreasing the risk of airway damage and secondary infection and the occurrence of lung barotrauma and volutrauma secondary to MV

Comparison of Early CPAP to Surfactant: Current Studies

- ✓ **COIN trial – enrolling spontaneously breathing infants of ≥ 25 weeks to 28 6/7ths weeks – DR CPAP (single nasal prong) vs IPPV +Surfactant**
- ✓ **VON - 3 arms, Early Surf + Vent, Early Surf + Early extubation, Early CPAP + Selective Intubation – All infants > 25 weeks Gestation**

Comparison of Early Surfactant with CPAP

- ✘ No study to date has addressed the most vulnerable population of infants of 24 weeks where survival is now > 50%
- ✓ NICHD Neonatal Network *SUPPORT* trial will compare Prophylactic/Early Surfactant (< 1 hour) to CPAP initiated at birth
- ✓ 2 Strata – 24 to 25 6/7wks and 26 to 27 6/7 wks
- ✓ Will evaluate Neonatal Survival without ROP, BPD and Neurodevelopmental Impairment at 2 years

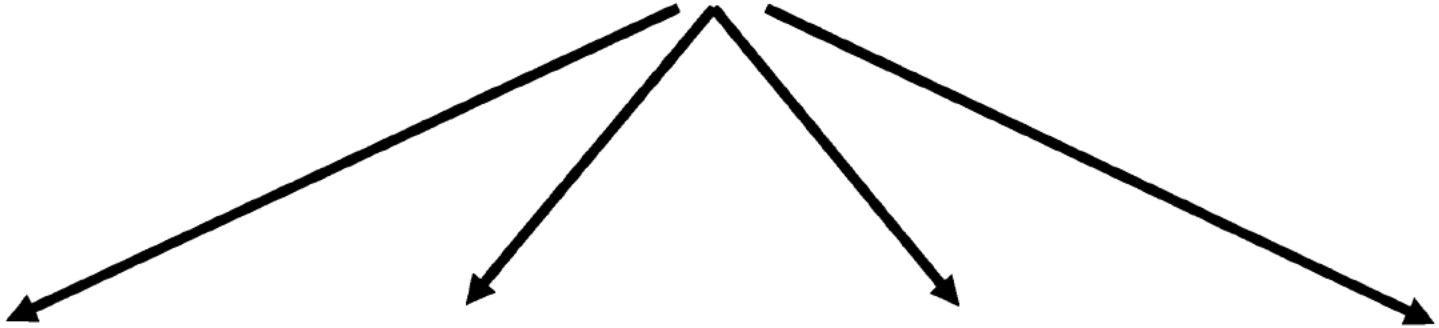
Next Trial : SUPPORT

- **Surfactant**
- **Positive airway pressure**
- **Pulse Oximetry**
- **Randomized**
- **Trial**

SUPPORT Trial

- **Essentially 2 trials conducted simultaneously on the same population of ELBW infants**
- **A Factorial design which ensures that there will be an equal number of infants randomized to each of the 4 possible strategies**
- **Not prospectively powered to evaluate an interaction, but if a large interaction exists, it will be noted**

Overall Study Design



CPAP + Lo SaO2 | CPAP + Hi SaO2 | SOC + Hi SaO2 | SOC + Lo SaO2

We hypothesize that that the use of CPAP and a permissive ventilatory strategy begun in the delivery room in infants of less than 28 weeks gestation with continuing CPAP in the NICU will result in an increased survival without CLD at 36 weeks.

We hypothesize that the use of a lower SaO2 range (85% to 89%) will result in an increase in survival without the occurrence of ROP or occurrence of threshold ROP and/or the need for surgical intervention.

We hypothesize that the combination of early CPAP and a permissive ventilator strategy with a lower SaO2 range will result in increased long term survival without severe developmental impairment as assessed at 18-22 months corrected age.

SUPPORT Trial

Randomized Intervention	Low SpO2 85% to 89%	High SpO2 91 to 95%
Early CPAP With Permissive Ventilation	Early CPAP + Low SpO2	Early CPAP + High SpO2
Control with Prophylactic Surfactant	Control + Low SpO2	Control + High SpO2

PRIMARY HYPOTHESIS

- **EARLY CPAP AND PERMISSIVE VENTILATORY STRATEGY WILL INCREASE SURVIVAL OF ELBW INFANTS WITHOUT BPD**

- **LOWER SpO2 (85-89%) WILL INCREASE SURVIVAL WITHOUT SEVERE ROP (THRESHOLD DISEASE OR REQUIRING SURGERY)**

Methods: CPAP/Permissive Ventilatory Strategy

- DR management guidelines
- Intubation criteria
- Extubation criteria
- Re-intubation criteria

SUPPORT Trial: Inclusion Criteria

- **Infants with a minimal gestational age of 24 weeks 0 days to 27 completed weeks (up to 27 6/7ths) by best obstetrical estimate**
- **Infants who will receive full resuscitation as necessary, i.e., no parental request or physician decision to forego resuscitation**
- **Infants whose parents/legal guardians have provided consent for enrollment, or**
- **Infants without known major congenital malformations**

SUPPORT Trial: Exclusion Criteria

- Any infant transported to the center after delivery
- Infants whose parents/legal guardians refuse consent
- Infants born during a time when the research apparatus/study personnel are not available.
- Infants < 24 weeks 0 days or $\geq$ 28 weeks 0 days, completed weeks of gestation

SUPPORT - Ventilation Arm

- **Will test the use of early CPAP started in the delivery area combined with a permissive ventilator strategy compared to a standard of care approach involving prophylactic/early surfactant within 1 hour of delivery**

SUPPORT TRIAL

Ventilation Strategies - First Hour

Treatment Arm

DR CPAP

Control Arm

Intubation and Early Surfactant < 1 hr

SUPPORT TRIAL
Ventilation Strategies - NICU

Treatment CPAP Arm

Intubation Criteria – Intubation is *Not Mandatory* for CPAP infants

May intubate CPAP Infants for Any of

FiO_2 >.50 for $SpO_2 \leq 88\%$
$PaCO_2$ > 65 torr
Hemodynamic instability

SUPPORT TRIAL
Extubation for TREATMENT - CPAP Infants

Must *Extubate* within 24 hrs of all criteria being met

$PaCO_2$ < 65 torr and pH > 7.20
SpO2 ≥ 88% with FiO2 ≤ .50
MAP < 10 cmH_20 Rate ≤ 20 bpm
Amp < 2X MAP if on HFV
Hemodynamically Stable

Criteria apply for first 14 days of life

SUPPORT TRIAL
Re-Intubation for TREATMENT - CPAP Infants

May *Intubate* within 24 hrs of all criteria being met

- **$PaCO_2 < 65$ torr and pH > 7.20**
- **$SpO_2 \geq 88\%$ with $FiO_2 \leq .50$**
- **Hemodynamic Instability**

Criteria apply for first 14 days of life

CPAP Arm
Reintubation - Extubation

- **Once a CPAP infant has been intubated for the *third time*, that infant's subsequent management will follow unit standard of care**
- **We do not want to create artificial/protocol driven cycles of intubation/extubation**
- **For such infants subsequent extubation will be at the attending physician's discretion**

SUPPORT TRIAL
Ventilation Strategies - NICU

Control Surfactant Arm

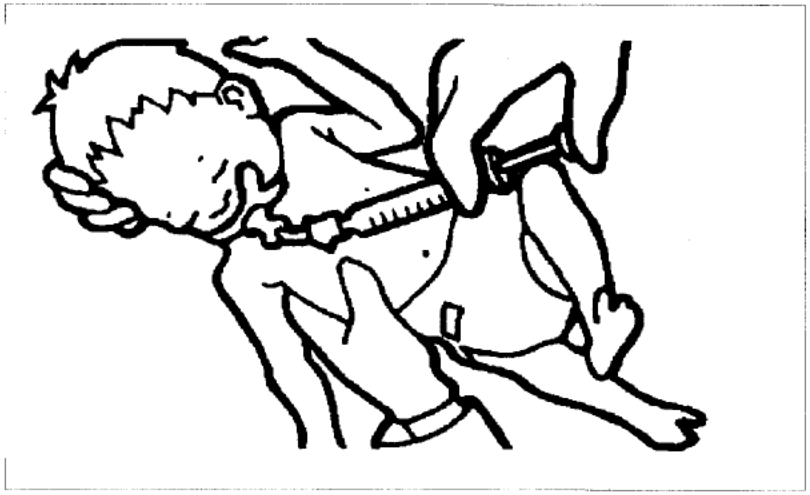
Will remain Intubated until they meet the following Criteria
Extubation can take place within 24 hrs of criteria

- **FiO2 < .35 for SpO2 ≥ 88%**

pH > 7.30 and PaCO2 < 50 torr
MAP < 8 cm H_2O, Rate ≤ 20 bpm,
If HiFi, Amplitude < 2X MAP
Hemodynamically stable
No significant PDA

SUPPORT TRIAL

Re-intubation Criteria - Control - Surfactant



Once extubated, a Control – Surfactant infant may be re-intubated following current Standard of Care

SUPPORT - Ventilation Arm

- **Treatment infants will be forced to early extubation attempt at higher ventilation settings**
- **Control infants will be extubated at more conventional settings**
- **Spontaneous extubation will not require mandatory re-intubation, unless intubation criteria are met.**
- **Intubation may be performed at any time for apnea, sepsis, shock or surgery**

Ventilation Criteria

- **In effect for 14 days for all study infants**
- **CPAP may be discontinued when in room air > 1 hour**
- **May be restarted at any time in either group**
- **Nasal SIMV to be used *only* after initial intubation**

Oximetry Arm: Justification

- **There are major questions regarding the appropriate level of oxygen exposure during the acute management of the ELBW infant**
- **Retrospective data suggests that infants maintained SpO2 values of 88% to 98% had 4 times the incidence of ROP as infants managed with lower SpO2 values - as low as 70% (Tin et al, Arch Dis Child Fetal Neonatal Ed. 2001 Mar; 84(2):F106-10.)**

Oximetry Arm: Justification

- **Chow et al at Cedars in LA adopted an approach which involved a number of interventions including less oxygen during resuscitation, and a subsequent SpO2 range of 85% to 93% for infants < 32**
- **They reported a significant decrease in ROP Grades 3 to 4 from 12.5% in 1997 to 2.5% in 2001 and ROP laser treatment from 4.5% in 1997 to 0% in the last 3 years of this intervention (Pediatr 2003; 111(2):339-345)**

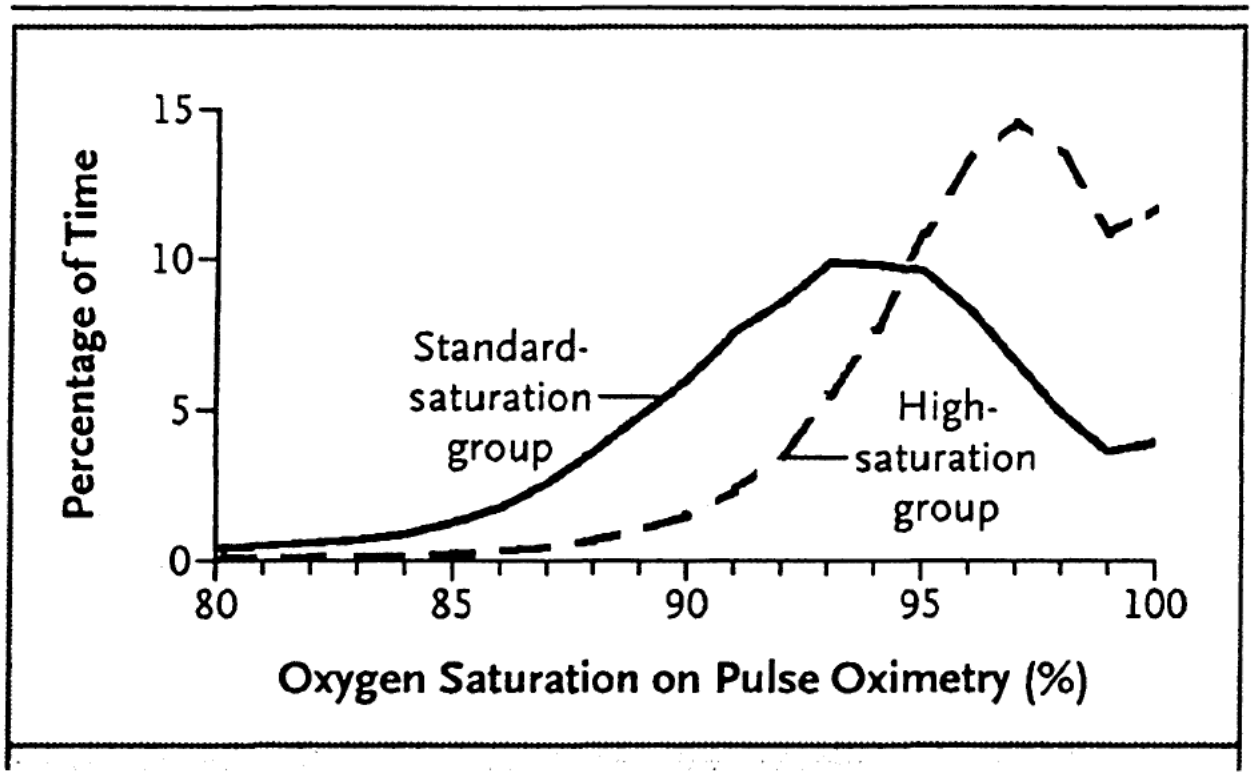
Oximetry Arm

- No other trial has prospectively evaluated the SpO2 level from birth onwards
- BOOST and STOP-ROP began when infants were $\geq$ 32 weeks of age
- They used ranges of 91-94% and 95-98%
- They both reported more pulmonary morbidity and a longer need for oxygen in their high saturation group where SpO2 was $\geq$ 95%
- Our study will keep SpO2 $\leq$ 95% for both groups

BOOST Trial
Askie et al, NEJM 2003;349;959

- **BOOST used a 2% adjustment in the SpO2 reading**
- **Low range infants read 2% lower than actual and hi range infants read 2% higher throughout the entire SpO2 range.**
- **Target range was 93 – 96%**

SpO2 from BOOST Trial
Askie et al NEJM 2003;349:959-67



Methods: Oxygen Saturation Strategy

Birth – Admit to NICU
Placed on Study Pulse Oximeter < 2 hours

SpO_2 – 85% - 89% **SpO_2 – 91% - 95%**

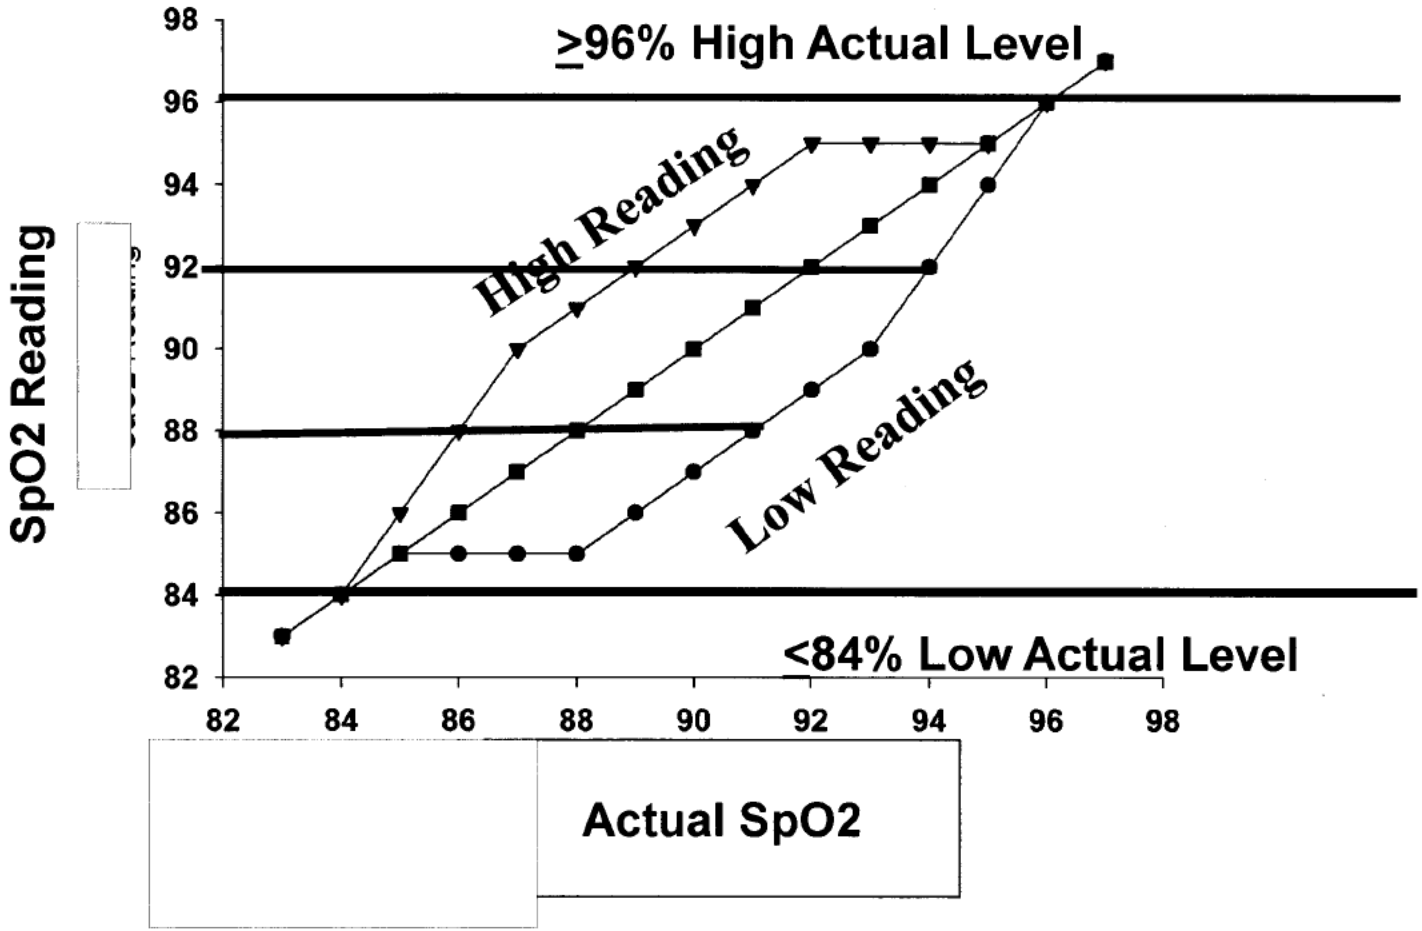
Maintain till off ventilatory support and oxygen

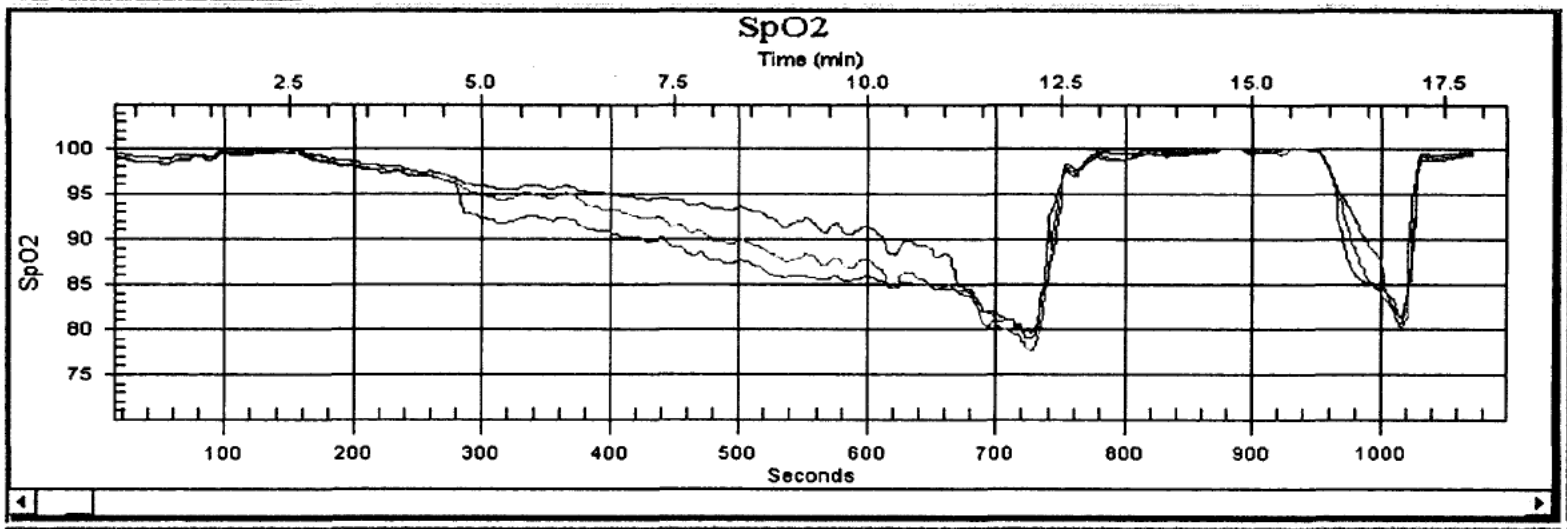
RANDOMIZATION	Displayed Target Range	Actual Range
Low SpO_2 range group	88-92%	85-89%
High SpO_2 range group	88-92%	91-95%

Pulse Oximetry Protocol

- **LOW RANGE: TARGET SpO2 85-89%**
- **HIGH RANGE: TARGET SpO2 91-95%**
- **STUDY PULSE OXIMETERS (PO) WILL BE SUPPLIED TO PARTICIPATING SITE**
- **STUDY PO'S READING NOT THE ACTUAL SpO2 for READINGS BETWEEN 85% TO 95% FOR BLINDING**

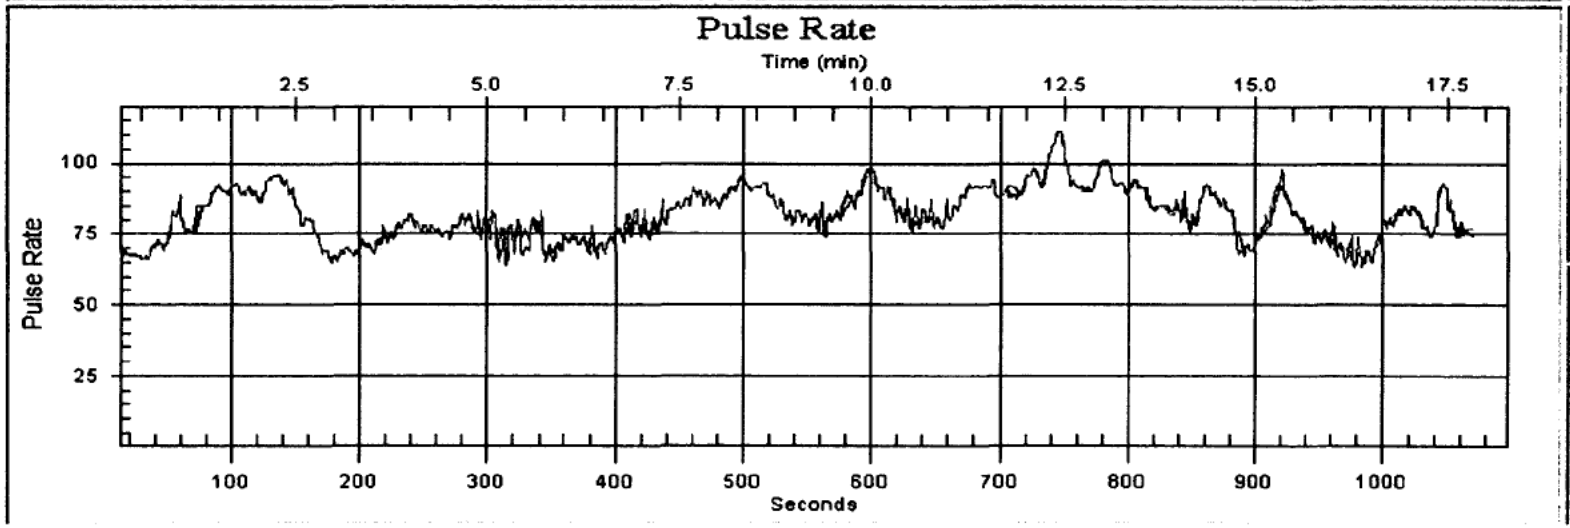
Plot of Actual versus Displayed SpO2



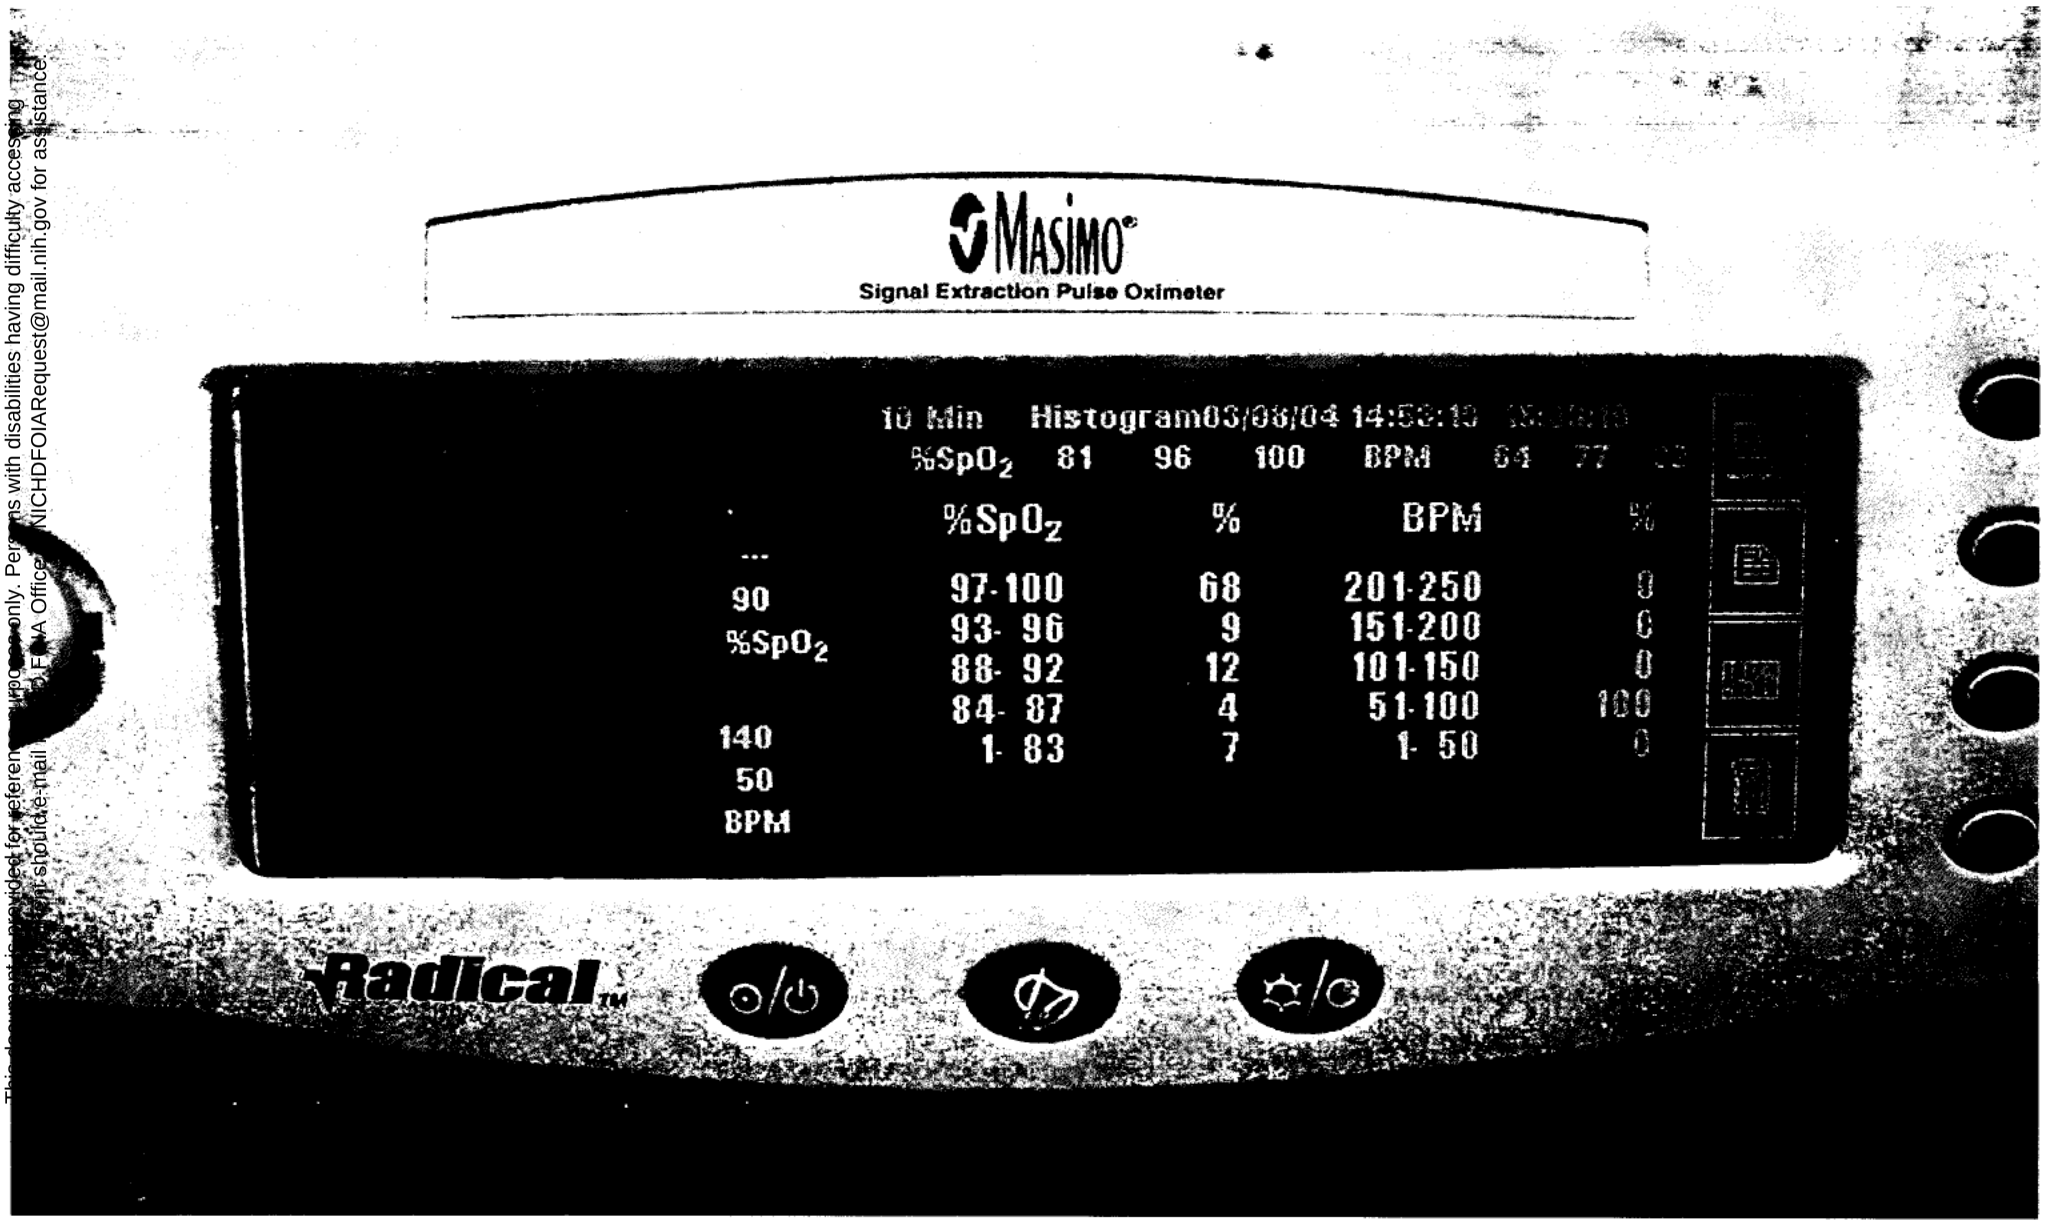


SpO2 Instruments:
REF Radical SpO2
Low Group : SpO2
High Group : SpO2

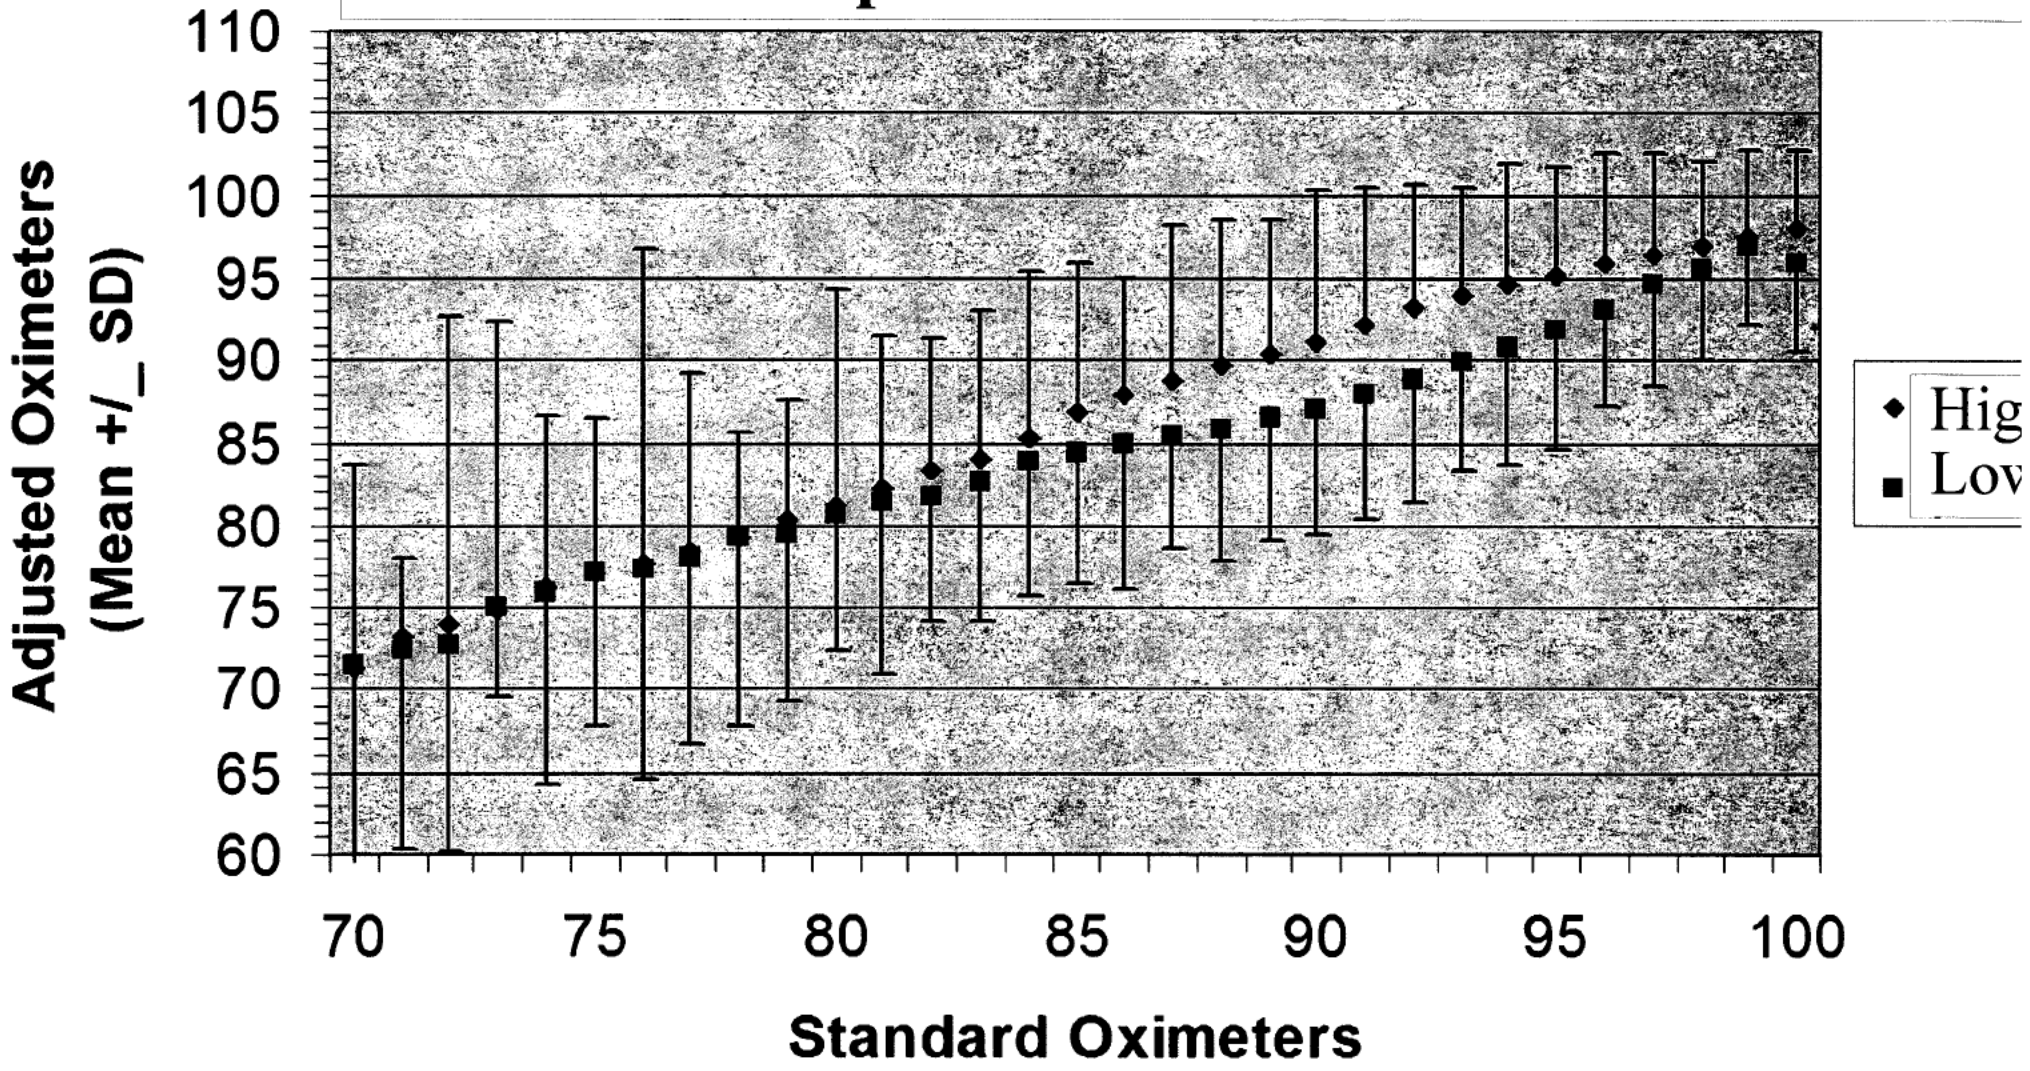
SpO2 Comment:

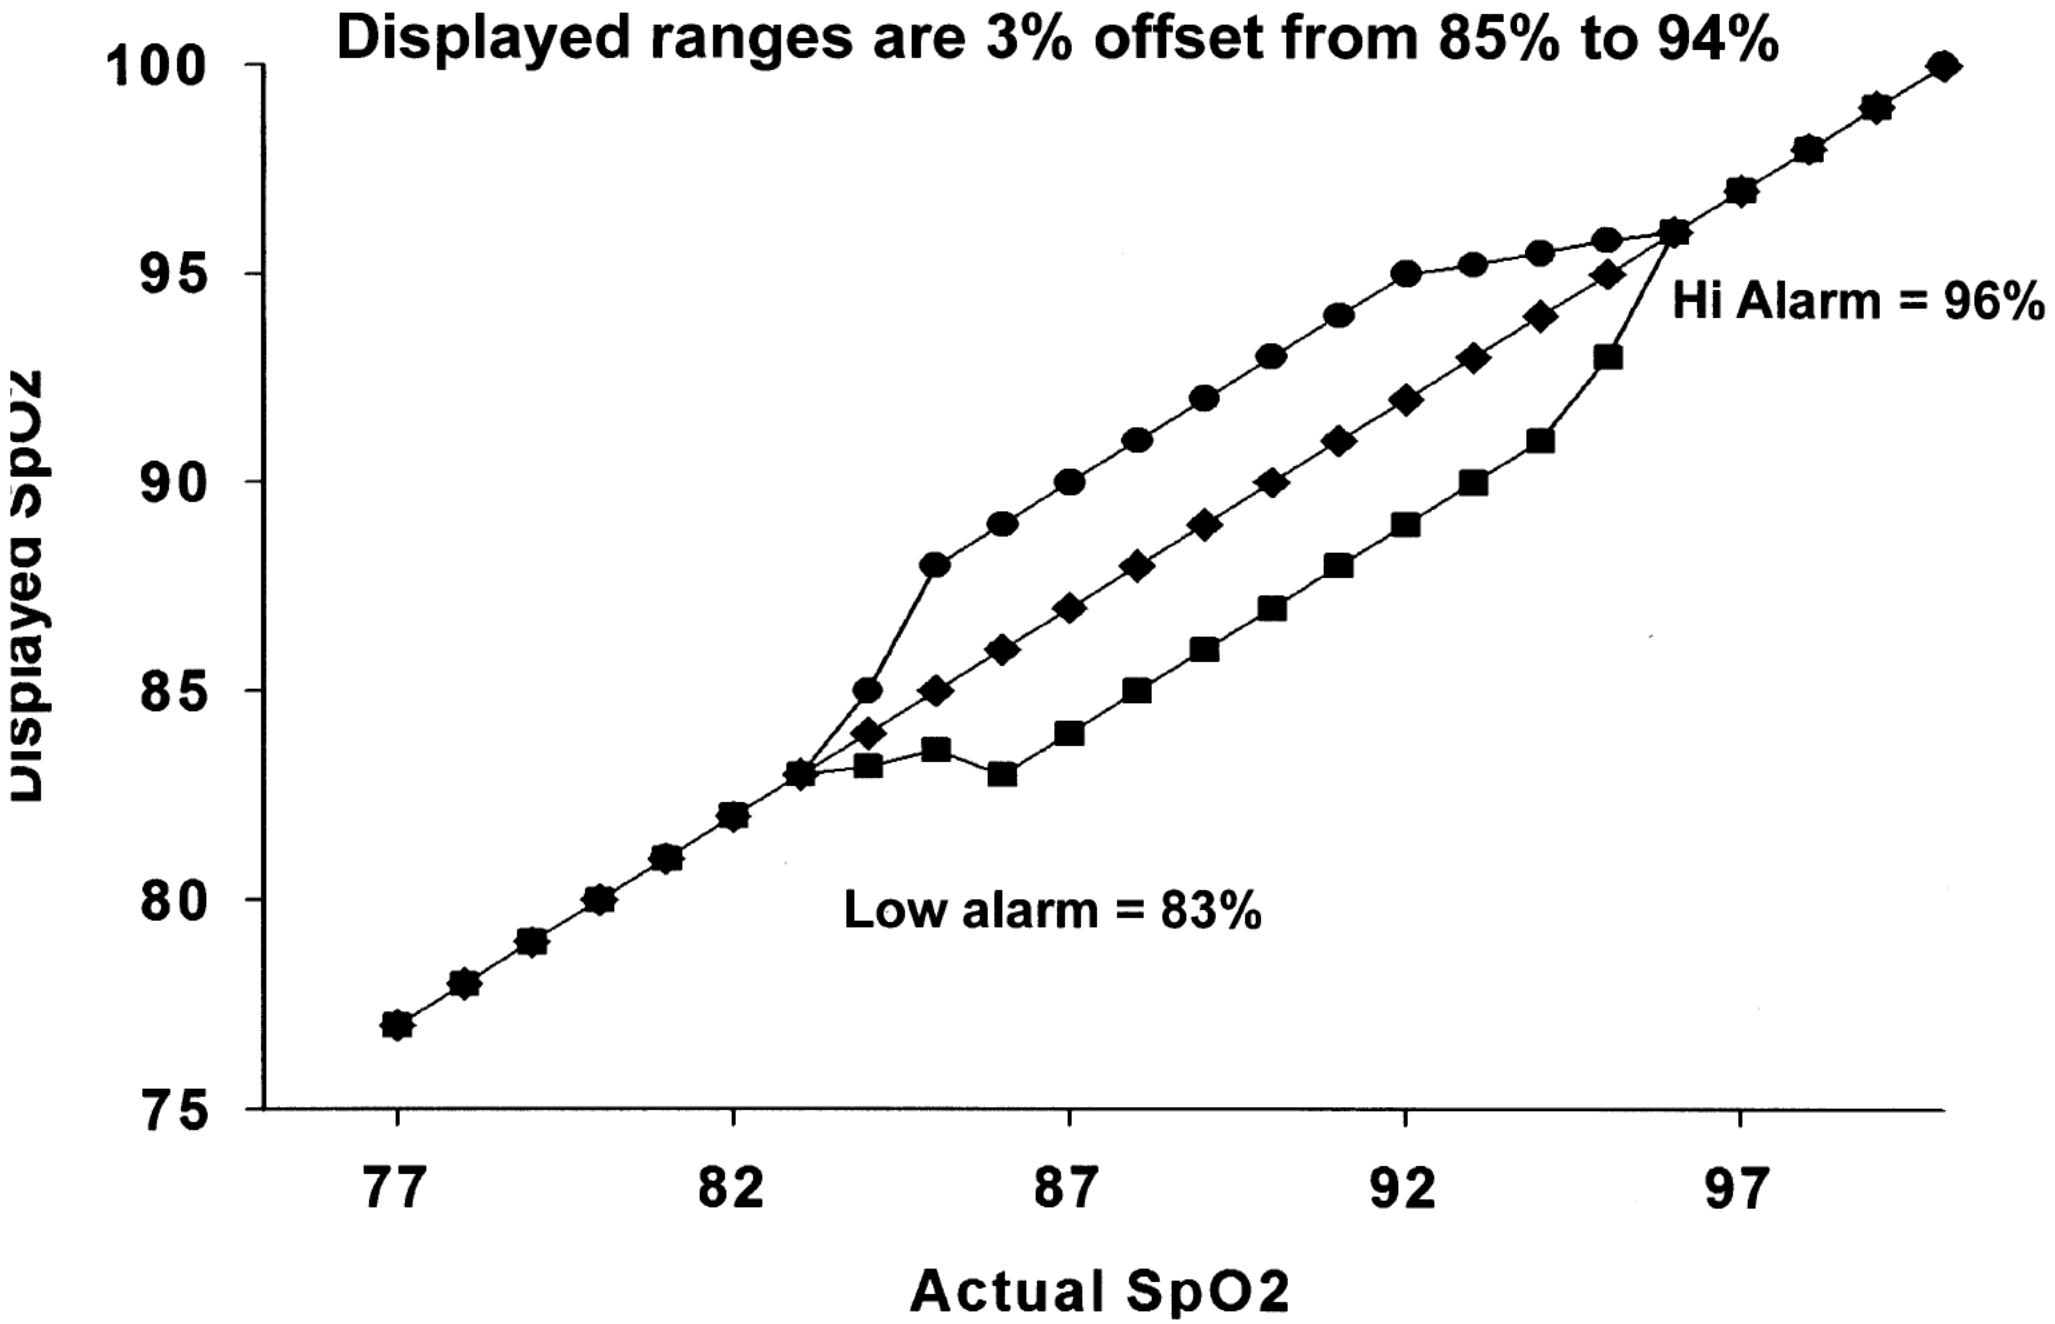


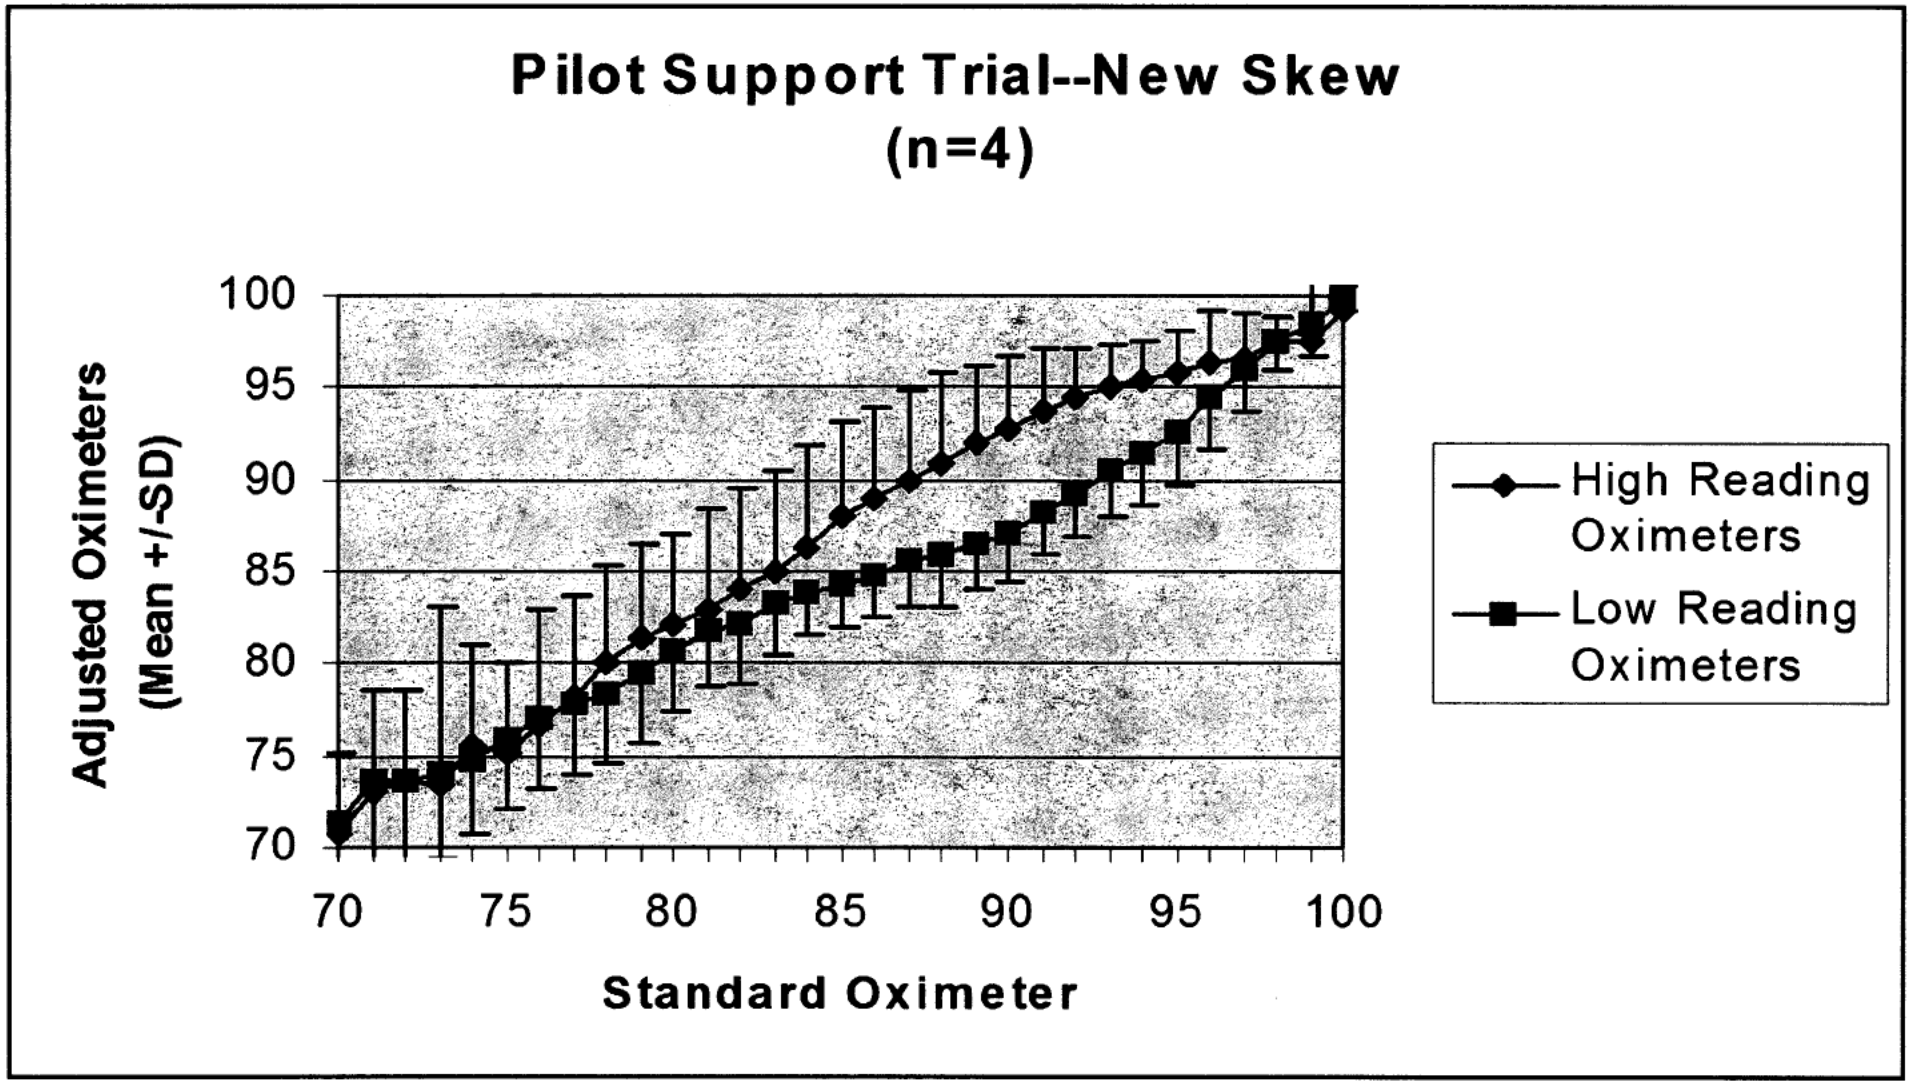
Pulse Rate Instrument
REF Radical PR
Low Group : PR
High Group : PR



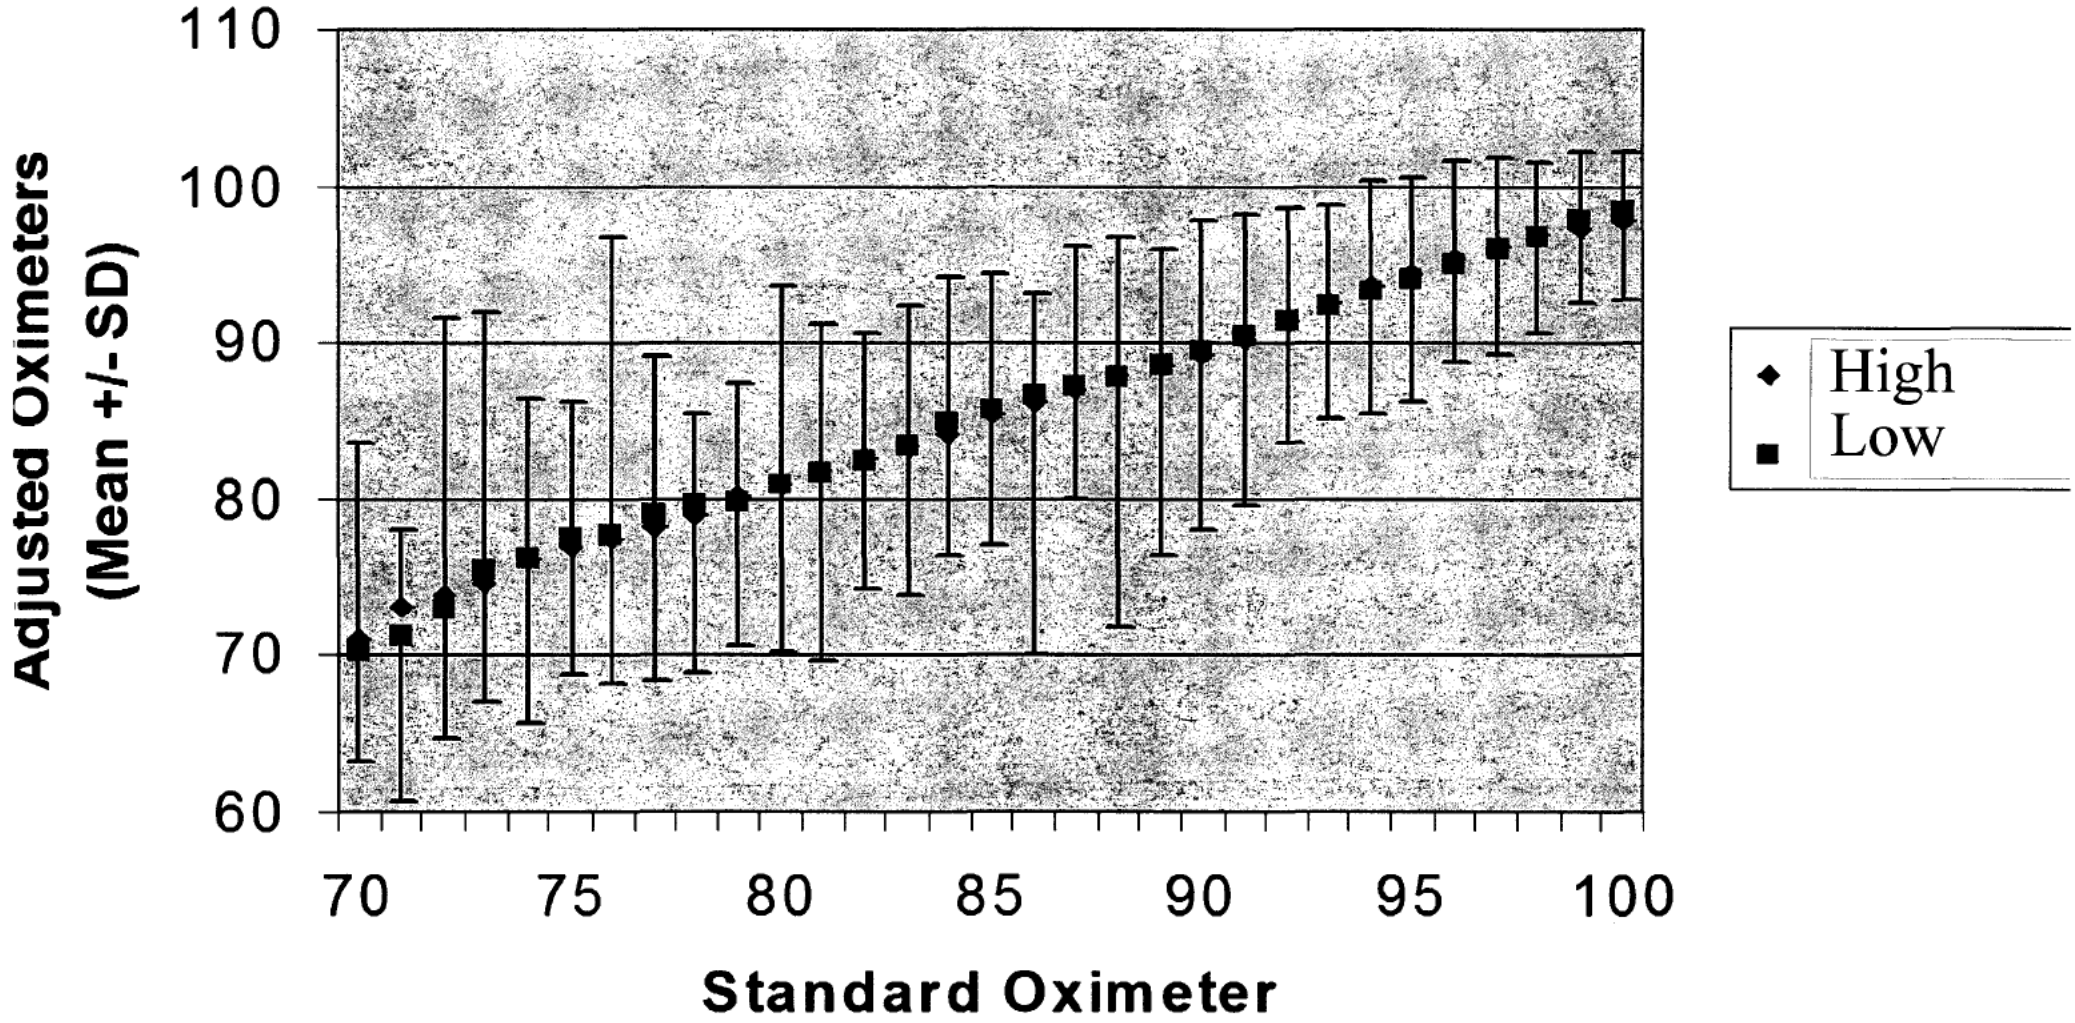
Comparison of High reading versus Low reading Oximeters Compared to a Standard Oximeter







Comparison of High reading versus Low reading Oximeters Corrected to Standard Readings



Pulse Oximetry Protocol

- **BOTH GROUPS WILL MAINTAIN DISPLAYED SATURATION AT 88-92%**
- **ALARMS FOR BOTH GROUPS WILL BE:**

  LOW – 85% HIGH - 95%

  (***Note Masimo alarms at actual limit set point, not one below*****)**
- **SPO2 READINGS BELOW 85% AND ABOVE 95% WILL BE ACTUAL, NOT ALTERED**

OXYGENATION PROTOCOL-CONT'D

- **STUDY PO WILL REMAIN WITH INFANT UNTIL OFF OXYGEN (for 3 days) or INFANT 36 WEEKS PCA whichever is sooner**
- **SpO2 FROM STUDY PO WILL BE DOWNLOADED TO RTI ONCE PER MONTH - every 2 WEEKS DURING STUDY**
- **This will contain 1 data point for SpO2 and heart rate for every 10 seconds of this 1 month interval**

Sample Size Estimate

- **The sample size depends on the outcome rate only through the standard deviation of the rate and this turns out to be essentially 50% for all subgroups (i.e. ranges from 49.7% to 50.0%). Hence one sample size table suffices for all.**
- **We will randomize by family, all multiples to same arm – we have made a 12% adjustment to sample size to account for this clustering.**

Sample Size

- **Postulating a 10% difference in primary outcome a sample size of 1310 infants will provide for 80% power for the primary as well as NDI/Mortality (Secondary Outcome)**
- **This includes a 17% attrition factor**

SUPPORT – Current Status

- ✓ Enrollment now almost 100 infants
- ✓ We have downloaded about oximeters with 2-4 weeks of data
- ✓ We are within the large target zone of 85% to 95% approximately 55% to 60% of the time
- ✓ This is the zone with the altered SpO2 values

SUPPORT – Current Status

- Downloads better done every 14 days.
- After 28 days you start to loose data!!
- Few issues with respiratory support protocols
- Oximeters – some increased alarms
- This depends on type and settings of oximeters that were previously used.

Safety Monitoring

- **We are going to monitor the occurrence of death, Grade 3 and 4 IVH, pneumothoraces in the first 14 days, the need for compressions or epinephrine in the DR.**
  DSMC has been given the rates of occurrence of each of these, overall and per strata.
- **If these occurrences are greater in any arm(s) of the trial, this information will be available to the DSMC (which has been expanded for this trial), and that arm(s) may be stopped.**

Conclusions

- **All of these studies will provide evidence to allow a determination of best practice for the ELBW Infant**
- **The best practice may differ for the infants < 26 weeks compared to infants > 26 weeks**
- **We should hold any judgments till we evaluate longer –term outcomes to avoid the mistakes of the past!!**

When Does My Alarm Sound?

Masimo

- A low alarm set at 85 alarms at 85.
- An alarm delay of up to 10 seconds may be used.
- Default low limit 90% for Neonates
- Averaging time from 2-16 seconds

Nellcor

- A low alarm set at 85 alarms at 84.
- Sat Seconds (Area under Time/Sat curve) of up to 100 seconds.
- Default low limit 80% for Neonates
- Averaging 2-4 seconds in Fast Mode, 4-7 seconds in Normal

Nellcor OxiMax

- ✓ **The *OxiMax* algorithm automatically extends the amount of data required for measuring SpO2 and pulse rate depending on the measurement conditions. During normal measurement conditions the averaging time is 6-7 seconds.**
- ✓ **During challenging measurement, conditions which could be caused by low perfusion, motion, external interference like ambient light, or a combination of these, the OXIMAX algorithm automatically extends the amount of data required beyond 7 seconds.**

Nellcor OxiMax

- ✓ If the resulting dynamic averaging time exceeds 20 seconds, the pulse search indicator is lit solid and SpO2 and Pulse Rate will continue to be updated every second.
- ✓ As these conditions become even more challenging, the amount of data required continues to extend. If the dynamic averaging time reaches 40 seconds, the pulse search indicator begins flashing, the SpO2 and pulse rate displays flash zeros indicating a loss-of-pulse condition.

Nellcor Sat Seconds

- **The SatSeconds limit controls the time that the %SpO2 level may fall outside the alarm before an audible alarm sounds.**

The method of calculation is as follows:

- **The number of percentage points that the %SpO2 falls outside of the alarm limit is multiplied by the number of seconds that the %SpO2 level remains outside that limit. This can be stated as an equation:**
- **Points x Seconds = SatSeconds**

- **Factory default low alarm limit is 80%**
- **If have a desaturation below 80%**
- **Then the oximeter counts each second**
- **A desaturation to 75% for 5 seconds**
  - 5 X 5% = 25 satseconds

Caveat Emptor

- **The *SatSeconds* "Safety Net" is for patients with saturation levels having frequent excursions below the limit, but not staying below the limit long enough for the *SatSeconds* time setting to be reached.**
- **When 3 or more limit violations occur within 60 seconds, an alarm will sound even if the *SatSeconds* time setting has not been reached.**

Masimo Oximeter

- **Has second level alarm 5% below the low alarm setting and if the SpO2 reaches this value there is an alarm with no delay – ie low alarm at 85%, then this second level alarm will sound if the SpO2 reaches 79%**

Using SatShare

- Can take signal out of Masimo oximeter for study and use Satshare cable to feed this into your normal bedside multi-parameter monitor ie Phillips, HP, etc
- The actual signal goes in as if it were the infants actual SpO2
- Thus if the Masimo is averaging at 16 seconds, each data point going in to the bedside represents the average of the previous 16 seconds with some weighting to the most current values

- **If the bedside monitor is now set to average it will further average using its own algorithm. The alarm settings will be those of the bedside monitor**
- **This is a method to avoid excessive alarms**

- **A NICU going from a Nellcor oximeter with its normal 4-7 second mode will now find that the Masimo is less responsive as it will average over a longer interval.**
- **The alarm settings will be different and there is no SatShare**
- **Thus, there may be more alarms, as the Nellcor is looking for time with an SpO2 < 80% and the Masimo will alarm with its delay at whatever it is set to, or immediately if 5% below this.**

- **Pulse Oximeters are accurate to ± 3%**
- **This it is possible to see 6% variation on new oximeters even of the same manufacture**
- **If Neonatal units in the current trial choose to set the low alarms at different levels ie < 80% as compared to 85% - the overall effect on the study will depend upon the amount of time that the infant is between 85% and 95%, and between 88% and 92%**

- **The maximum difference with the current Masimo study Oximeters will occur between about 87% and 93% and then the values slur towards normal**
- **They are normal at 84% and 96% to our testing**
- **If you maintain all infants between 80% and 85%**

There will be no difference in their SpO2 values, as these are identical values with both altered oximeters

Oximeter Information

- **The SUPPORT study group decided to set the limits of the altered oximeter values at 84% and 96% as this reflected the current practices in the various units and there was no evidence that lowering such limits was safe.**

Oximeter Information
SUPPORT Trial July 2005

- **At the present time based on the available downloads representing over 7000 hours of data we are in the range of 85% to 95% approximately 60% of the time for infants requiring oxygen, and 47% of the time for all infants irrespective of FiO2**

Neil
I likely have the bulk of the slides you need as I have the various SUPPORT Powerpoint slides that have been developed over the last year. Let me know if you want me to go through them to develop a back-up presentation in the event you continue to have email issues.

Don't worry about the meeting. My best to you and your family.
Take care
Rose

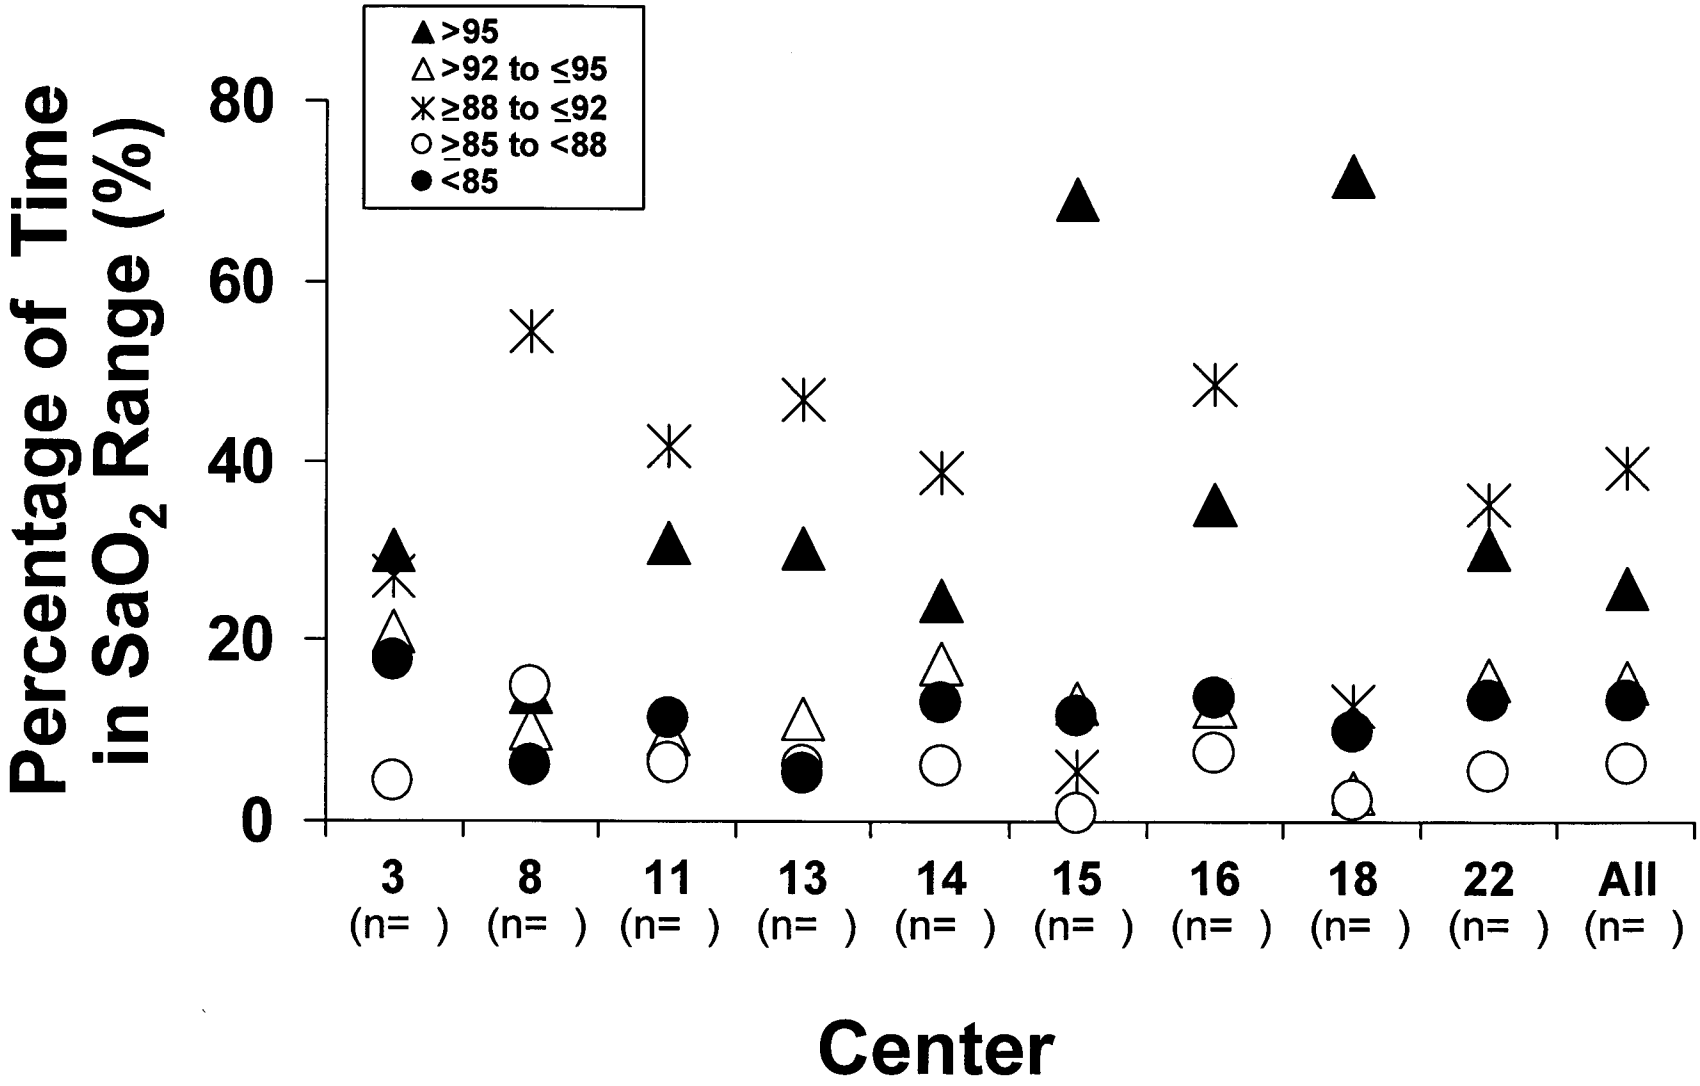
Dear All:
Thanks for your feedback. I have made minor changes on the graphs as described below and included a description to make it easier to follow and for the request to the DSMC as requested by Ken.

The changes include:

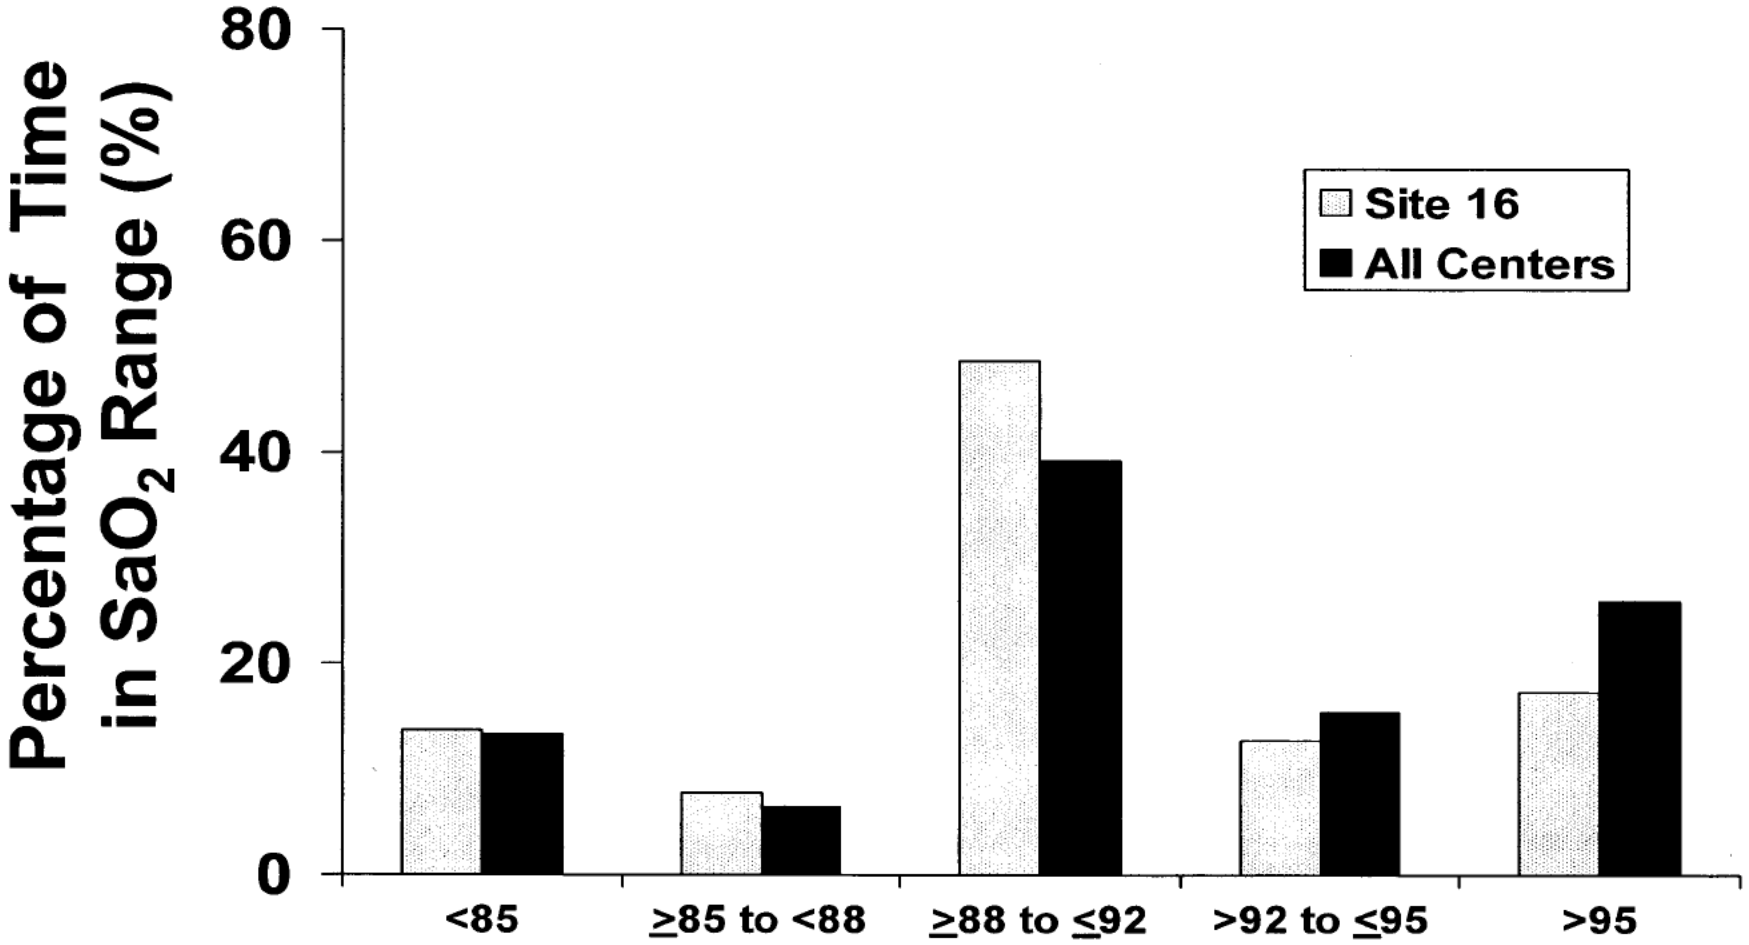
1. A title has been added to each graph to succinctly state what is depicted.
2. A detailed description (legend) of what each graph would show has been added
3. Minor changes to the x axis were made
4. The order of the graphs have been changed to make it more logical (one could argue the logic).

Thanks,
Wally

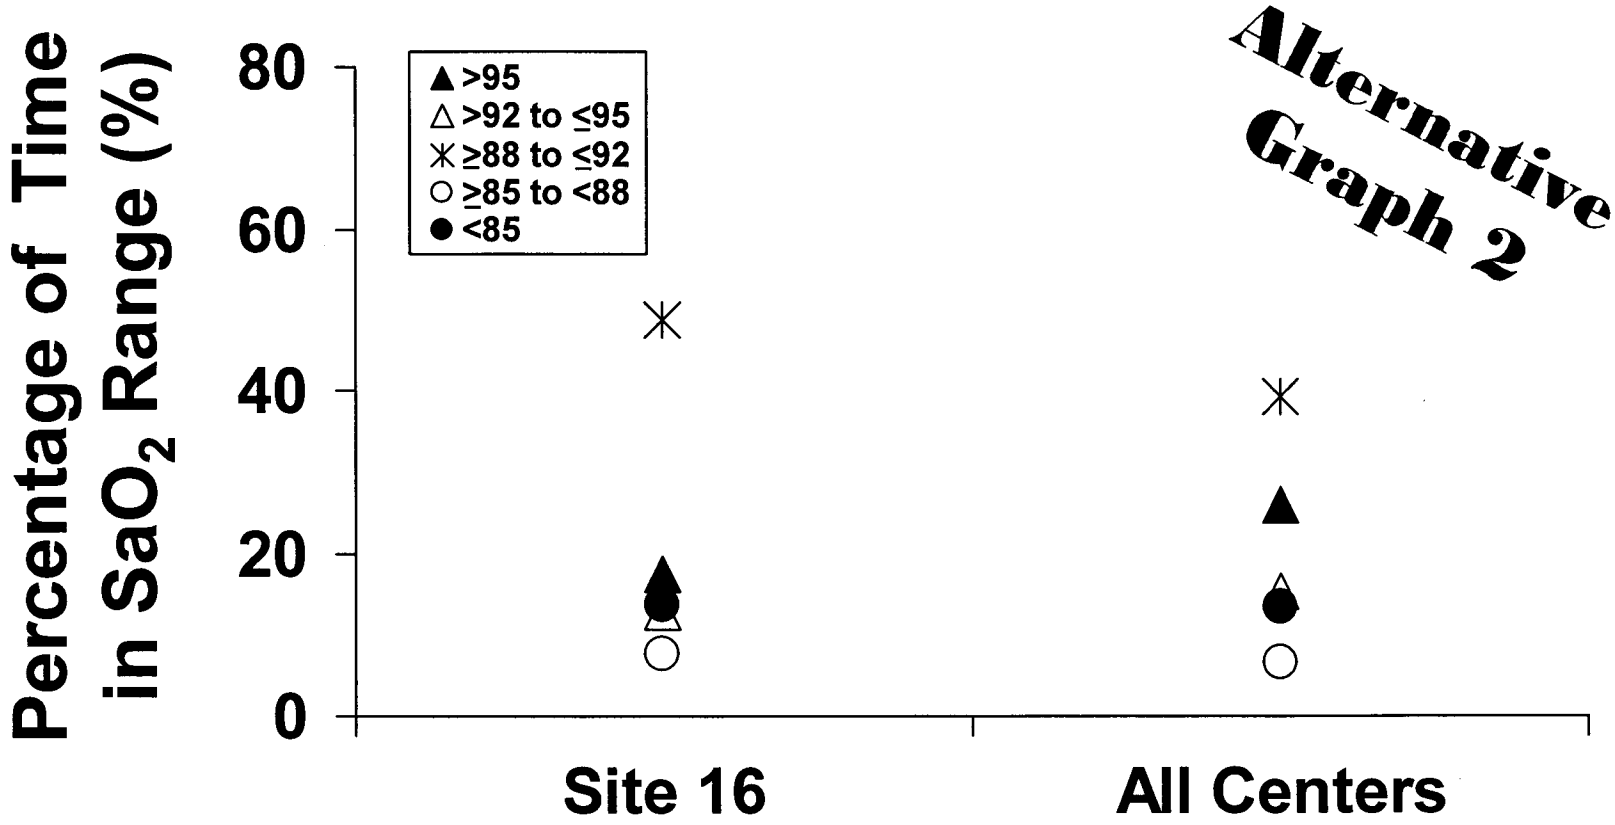
Cumulative Data of Percentage of Time in SaO_2 Ranges for each Center



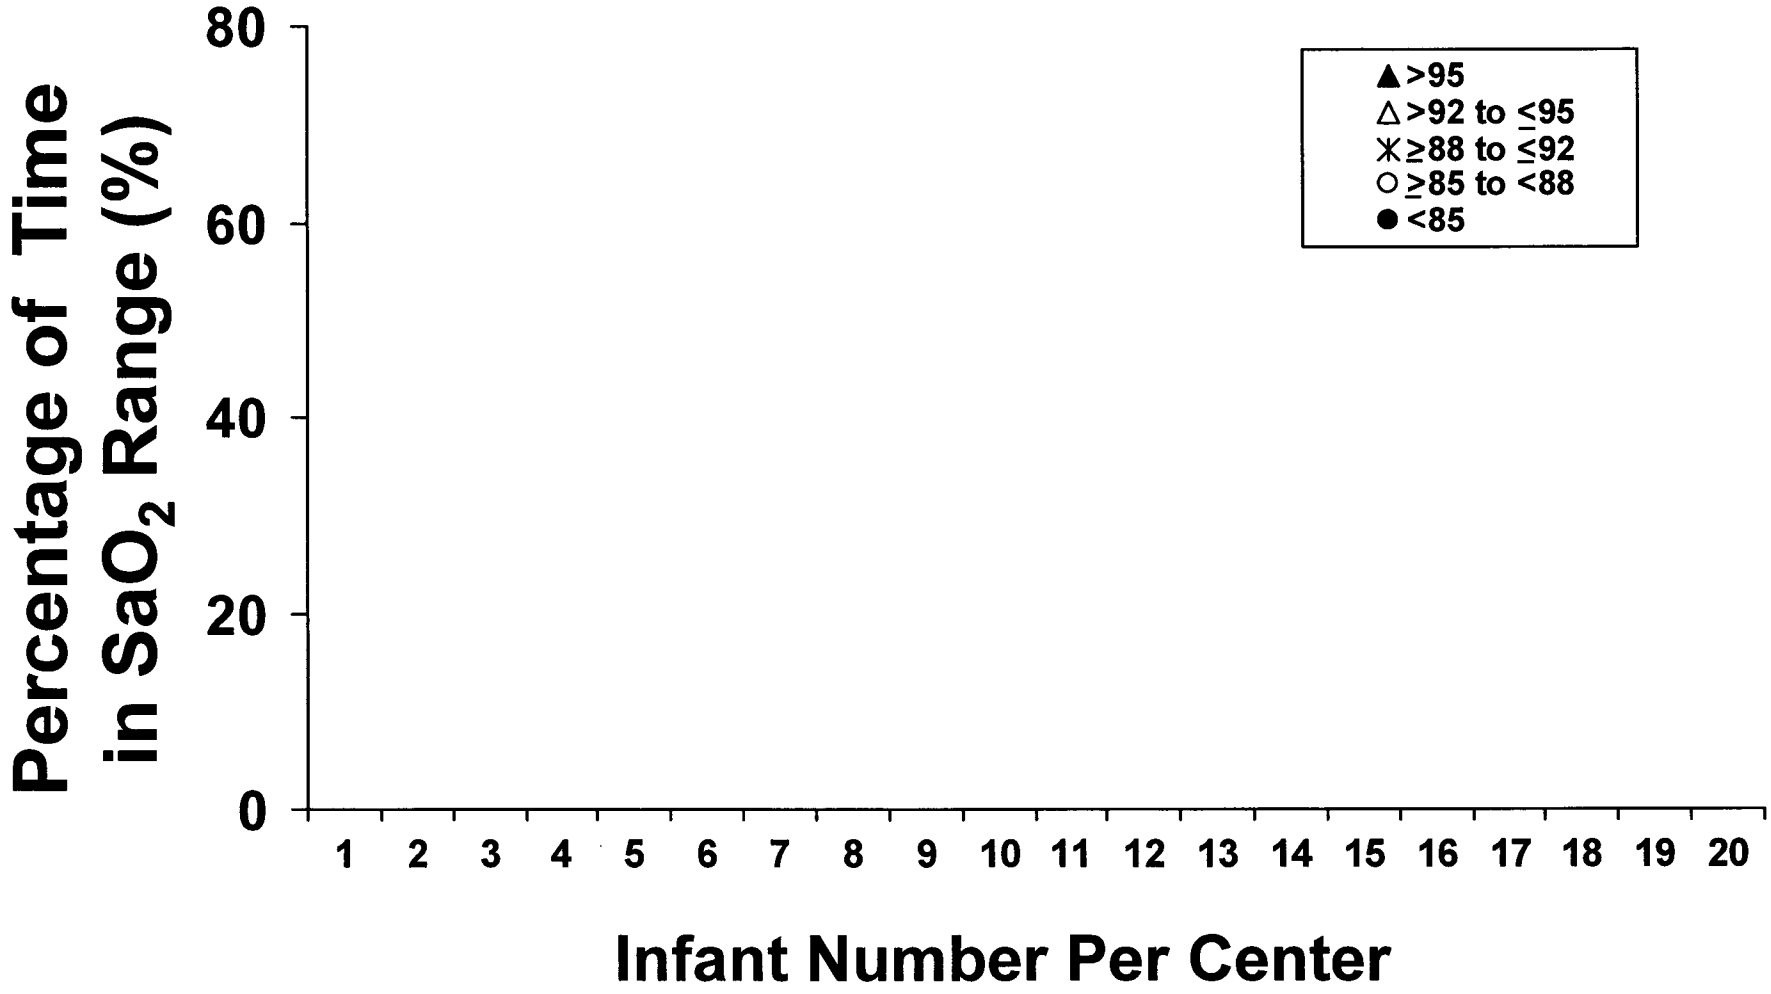
Cumulative Data of Percentage of Time in SaO_2 Ranges for Selected Centers Compared to All Center Data



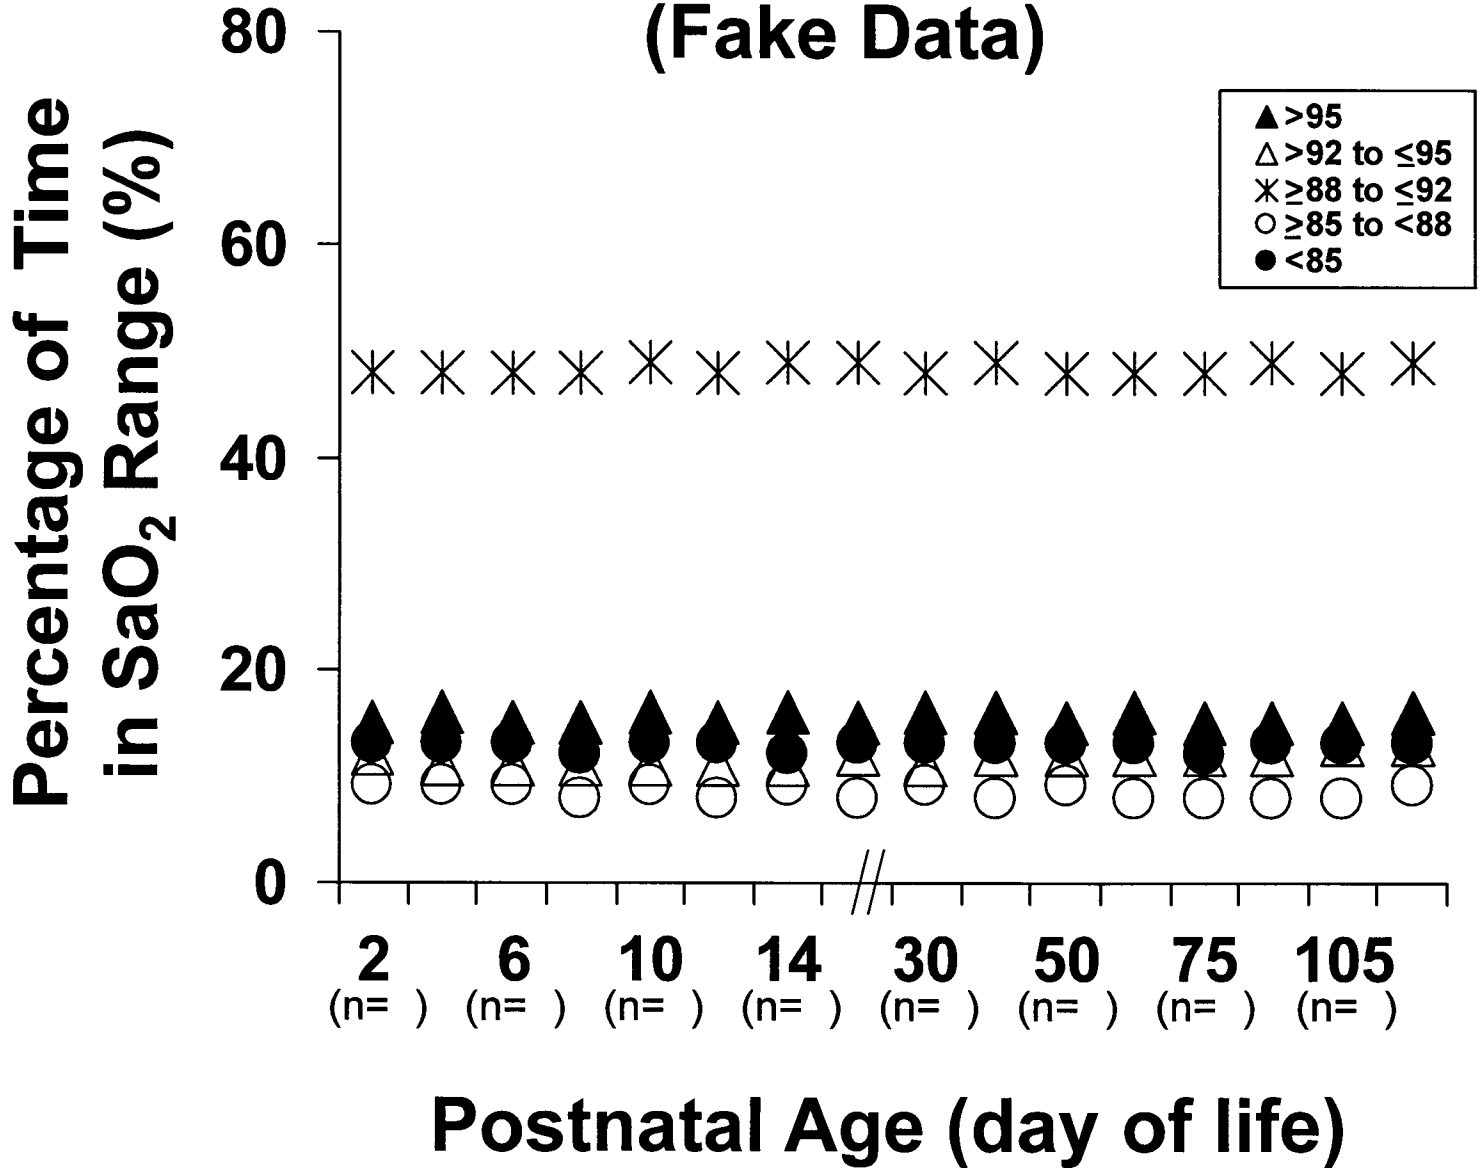
Cumulative Data of Percentage of Time in SaO_2 Ranges for Selected Centers Compared to All Center Data



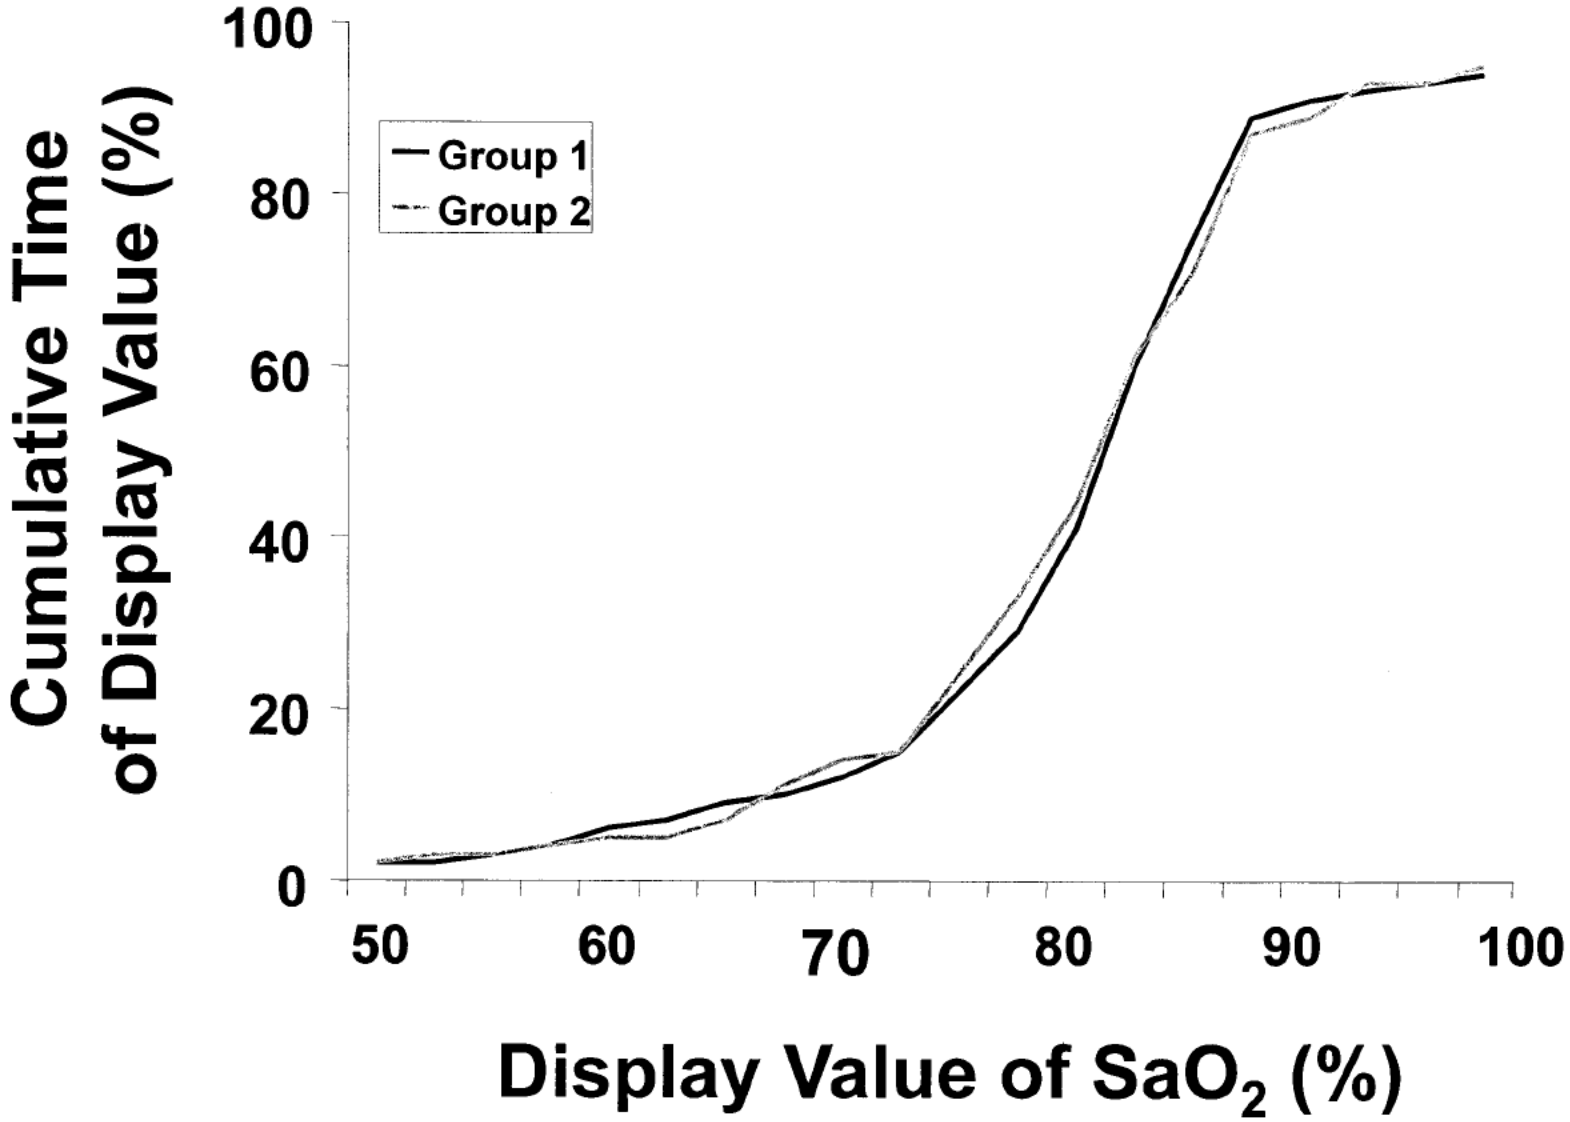
Cumulative Data by Percentage of Time in SaO_2 Ranges Depicted for Each Infant Consecutively Enrolled in Center X



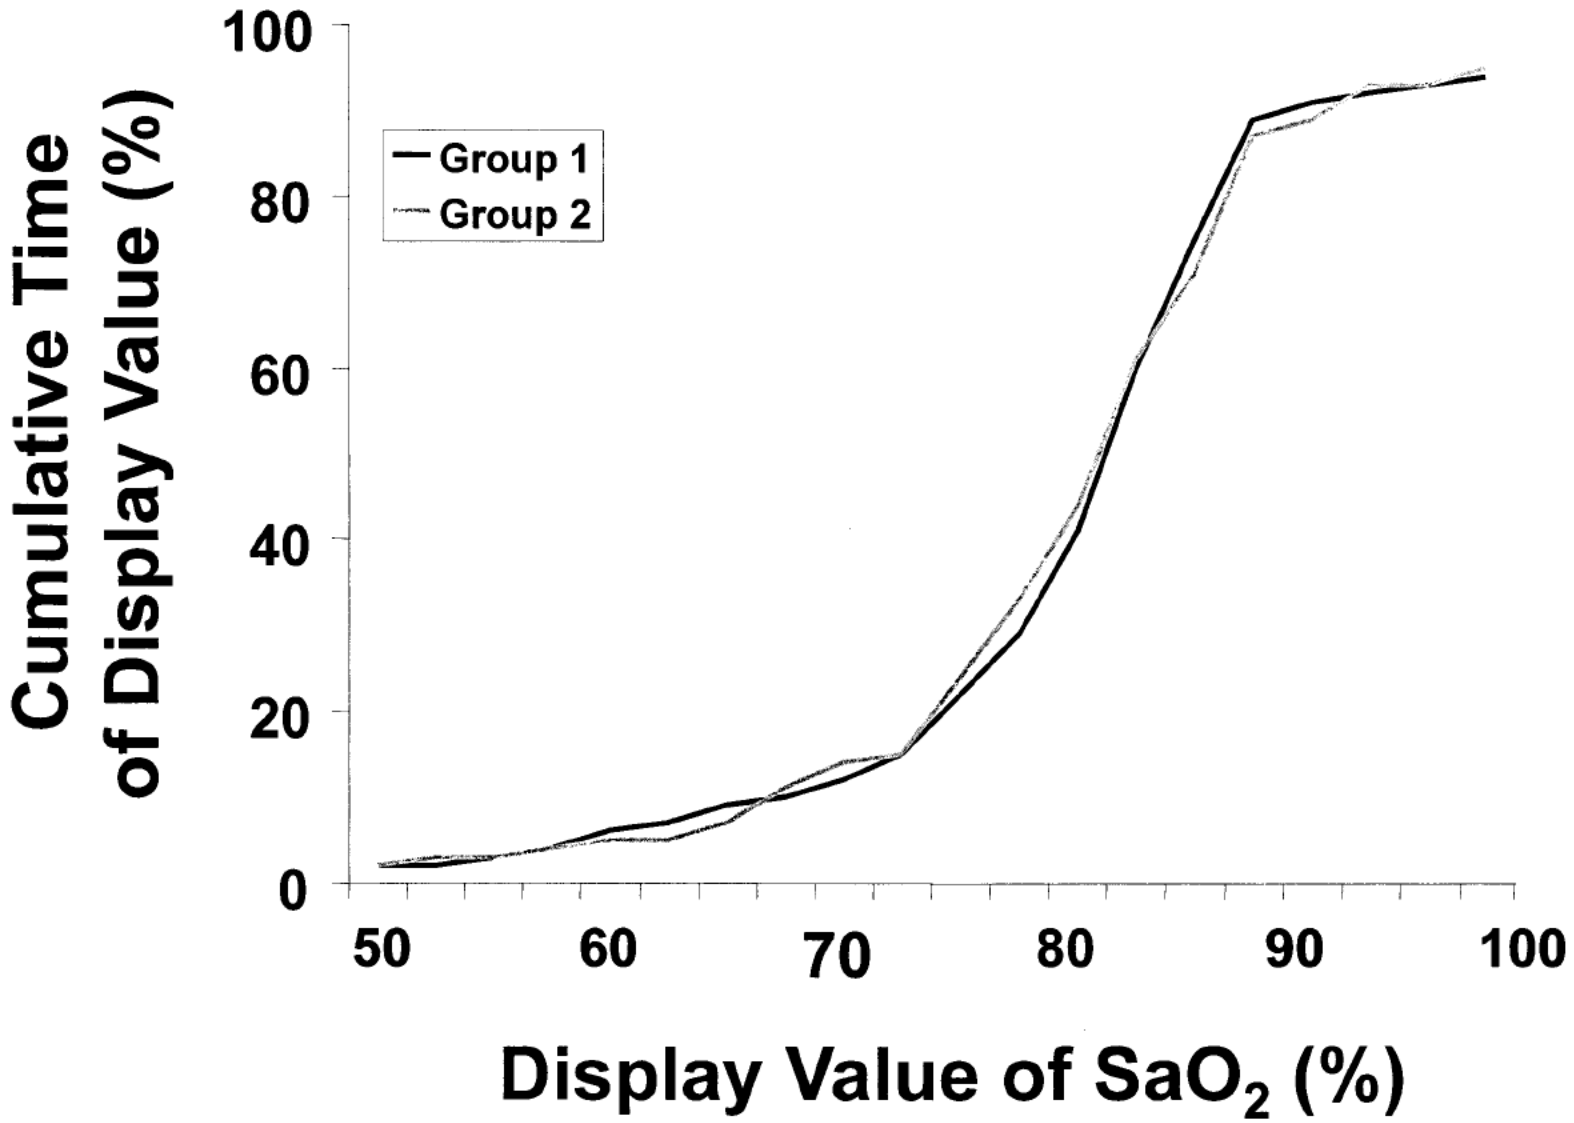
Cumulative Data of Percentage of Time in SaO_2 Ranges by Postnatal Age for All Infants in Center X (Fake Data)



Cumulative Data of Percentage of Time in Display SaO_2 Values for Infants in both Graphs for All Centers (Fake Data)



Cumulative Data of Percentage of Time in Display SaO_2 Values for Infants in both Graphs for Center X (Fake Data)



Legend

Graph 1: Cumulative data of percentage of time in SaO_2 ranges depicted for each center. The x-axis includes NRN Center number of each Center participating in SUPPORT. The number of infants (n) included per center is added under the center number. The star symbol is used for the target range. The open symbols add the ranges ($\geq$88 to $\leq$92% SaO_2) which optimized actual SaO_2 separation above (>92 to $\leq$95% SaO_2) and the range below ($\geq$85 to < 88% SaO_2) which complete the target. The closed symbols depict the range above (triangles) or below (circles) the target range (when alarms go off).

Graph 2: Cumulative of percentage of time in SaO_2 ranges depicted for selected center compared to All Center data. The symbols and ranges used are the same as in Graph 1. (We could use the same symbols and format as in Graph 1, shown as Alternative Graph 2).

Graph 3: Cumulative data of percentage of time in SaO_2 ranges depicted for each infant consecutively enrolled to date in a Center. The x-axis is the number of the consecutively enrolled infants within each center. The symbols and ranges are the same used in Graph 1.

Graph 4: Cumulative data of percentage of time in SaO_2 ranges depicted by postnatal age for all infants enrolled to date in each center. The x-axis is the postnatal age as day of life. The symbols and ranges are the same used in Graph 1. (Note that because of deaths, the number of infants decreases with postnatal age. The x-axis can be expanded as needed to included, for example each day).

Graph 5: Cumulative data of display values of SaO_2 for both groups (high and low SaO_2 display values) for All Centers. Overlapping of display values between 85 and 95 indicate good separation of total SaO_2 values.

Graph 6: Cumulative data of display values of SaO_2 for both groups (high and low SaO_2 display values) for Center X. Overlapping of display values between 85 and 95 indicate good separation of SaO_2 values.

Rose,
I think that the most efficient use of resources would be to wait for the network re-configuration and then move forward. Hopefully we would at that point be able to join the Phase 3. So I am voting for #3.
Mike

Subject: azithromycin BPD project

Hi,
At the last Steering committee meeting, Dr. Pablo Sanchez from UT Southwestern, Dallas presented a project on azithromycin and BPD. I need input from each of you with respect to how this should proceed. Please send me your choice of the following options by August 9, 2005:

1. Move forward with the pilots if funded
2. Move forward with pilots and main trial if funded (this impacts on SUPPORT, Inositol, and potentially probiotics which is currently under review)
3. Do not move on project at this point in time, wait for the network re-configuration (April 1, 2006)
4. Do not move forward on the project

I have reattached the proposal for your convenience.

Tim et al.

Below are some comments for the Pulmonary Outcomes study.

These are good questions. I think clarifying whether #2 includes well-child visits is important. I agree that multiple choice responses are better-might want to define occasionally and often with a range of times or just use a range of times. I would add aldactone to the med lists for both interviews. Defining whether Synagis was received in the first and/or second years of life would probably make the response clearer.

Date: Wednesday, August 03, 2005 12:55:33 PM

Hi Wally,

I think the slides look good and will clearly present the data. On slide 2, I would add n=..., by center, on the X axis, under center number. This will help to keep a rolling tab of numbers enrolled and better clarify subject composition of the 'total group' value in slide 4.

I think its fine to send the slides out at this time. How about also plotting center performance against group total, and sending out customized slides to centers already enrolling?

What do you think? Is it too early? I would like to have the sites aware that we are looking at the data, as it may help them educate their staffs.
Your thoughts
Thanks
Neil

Wally
Have we in the past looked at accumulating data in an RCT apart from the DSMC evaluations? This would require having the PaCO2 by group although not identified, and we would have to know which values we wanted – ie before or after intubation extubation etc.

Hi Wally
I do not believe that we should review study data that is not for safety. The downloads were designed to be available to us as feedback, and we can look at them without breaking the randomization as we look at the readout values, not the corrected values. If we look at PaCO2 overall, we will learn very little. To be meaningful we would need to know the levels of PaCO2 by the 2 vent groups, and I think that we would not want to look at such information at present. I need guidance here as to what we can and should legitimately look at. I will ask Rose to set up a call over the next 2 weeks.
Regards
Neil

Abhik,

We have reviewed 33 Support oximetry downloads at our center. 4 studies were truncated. All were of a duration of 30 days or greater. I believe that my original plan, which was to download every 4 weeks instead of every 30 days would have worked, but it leaves little room for error. Unless there is a rebelion on the Coordinator's call this week, I think it would be appropriate to continue to download every 2 weeks.

Wade

To: Poole, W. Kenneth; Das, Abhik; David Stevenson (dstevenson@stanford.edu)
Subject: FW: ROP forms

HI,
We have a "data issue" that I would like input for – the SUPPORT Trial is moving along and we need to be absolutely sure we have reliable and accurate ROP outcomes (some of these will be added after discharge). Dale has been extremely helpful with the ROP forms, but we need to insure that the ROP outcome is accurate. IN order to do this, the subcommittee thought it would be helpful if Dale could review the data forms. As this is a "data access issue" and investigators are usually NOT privy to non-site data during an ongoing trial so we were going to have Dale review the Rochester forms. However, Rochester may be most skilled in collecting this type of data due to there past experience with multiple ROP trials. So, the real question is "Should we allow Dale to review forms from other sites?" in order to write an accurate algorithm for the ROP outcome for the study?

Let me know your thoughts.

Thanks
Rose

Cc: Higgins, Rosemary (NIH/NICHD)
Subject: RE: ROP forms

Hmmmm,
I don't think so, because:

1) If we had gotten started earlier, it would be an ok plan, but we have not yet enrolled our first infant (one consented!)

2) My center already is skilled at follow up of ROP and therefore not representative of the centers that will have trouble.

Hi Everyone
I'm sure your bored to death this week with nothing to do – so here are the reports – Things are looking better, and we appear to be in the range of 85-95% about 60% of the time when the infants are on oxygen. I don't yet know how many infants this represents, but you can see that this report largely reflects the activities of 4 centers –Alabama, Houston, Brown and UCSD. Overall there is 26% of the time > 95% and 13% below 85%.
We should be approaching 100 infants, and Wally is going to look at the first 200.
We will discuss at the next conference call.
Be well
Neil

Subject: RE: SUPPORT time in target range

Hi Neil and Wade,

Attached are two documents showing the proportion of time patients are kept in the target pulse ox ranges at each center. The low and high cases are grouped together. In one document, the numbers are based on all the available pulse ox data. In the other, the numbers are only for days on which we know the babies spent time on supplemental O2. This determination is made using information from form SUPP05. If the baby was intubated/CPAP for >8 hours on a given day and the FiO2 value at 8:00, 16:00 or 23:59 was >.21 or if the baby was on cannula/hood for >8 on that day and FiO2 recorded closest to noon was >.21, then the baby was determined to be on supplemental O2 for that day.

As you will see, we could not identify many records corresponding to days spent on supplemental O2. There are a couple of reasons for this: (1) we have not received forms SUPP05 from some of the centers, (2) we only have information about supplemental O2 for the first 14 days of life, so pulse ox data for days 15 and higher are not included.

Please let me know if you have any questions.

Subject: SUPPORT time in target range

Neil and Wade,

Attached is a document showing the percent of time babies in the SUPPORT trial have been kept in the target SpO2 ranges. Separate percentages were calculated for the low and high SpO2 arms and for each center. Please note that these are the oximeter display values, not the actual SpO2 values. Also, note that the numbers are based on a very small number of babies. The tables include the number of babies and total number of hours of SpO2 data that went into calculating the percentages. The percent of time in each range is the overall percent of time babies at the center were kept in the range, as opposed to the average percent of time each baby was kept in the range. In other words, babies for whom more data were collected (over a longer period of time) are more heavily weighted in the percent calculations. If you have any questions regarding how these numbers were calculated, please let me know.

Subject: Re SUPPORT

Hello Neil, Wally and Rose,
Our first SUPPORT infant was born (b) (6) . A 246/7 weeks (b) (6) received a complete course of ANS, delivered by C-Section for complete cervical dilation. Randomized to early NCPAP and orange. Did very well in the delivery room. She required few breath from the Neopuff than was placed on nasal prongs CPAP with a peep valve in the delivery room and baby did well. she came to the NICU on nasal prongs CPAP. I just left the NICU and she was (b) (6) NCPAP 30% on the orange Massimo with a PaCO2 of 37. All went well in the delivery room. The NICU team is comfortable with the study and hopefully there will be no unforseen problems. I will call if we have any issues. Five ladies are on the high risk floor and have been consented.
Walid

A. ABSTRACT

Statement of Problem Premature infants have a greater risk for recurrent wheezing, chronic cough and more need for pulmonary care in early childhood than term infants (1-11). Although Chronic Lung Disease (CLD) is a risk factor, the etiology of symptomatic airway dysfunction, defined hereafter as recurrent wheezing and/or chronic cough, in formerly premature infants is not known.

Hypotheses The goal of this clinical project is to understand better the antecedents of symptomatic airway dysfunction among preterm infants during early childhood by evaluating the effect of treatment with different levels of targeted oxygen saturation in the immediate neonatal period. **The overarching hypothesis is that premature infants exposed to supplemental oxygen suffer oxidant stress in the lung in the immediate newborn period that results in impaired airway growth and development. These airway changes predispose premature infants to greater airway dysfunction and respiratory symptoms when challenged with subsequent environmental or infectious exposures.**

Hypothesis #1- Relative to infants managed with a higher SpO2 range, infants who are managed with a lower targeted SpO2 range will have less symptomatic airway dysfunction and reduced need for outpatient pulmonary care in the first 18-22 months' corrected age (CA), whether they develop CLD or not.

Hypothesis #2- Relative to infants managed with prophylactic surfactant and conventional ventilation, infants who are managed with the early use of CPAP and a permissive ventilator strategy will have less symptomatic airway dysfunction and reduced need for outpatient pulmonary care in the first 18-22 months' CA, whether they develop CLD or not.

Design
Longitudinal follow-up of infants enrolled in the SUPPORT Trial to determine the effect of lower targeted oxygen saturation ranges and more aggressive use of CPAP on the incidence of symptomatic airway dysfunction and volume of outpatient pulmonary care in the first 18-22 months' CA.

Definition of outcomes:

A) Parental Report Symptomatic Airway Dysfunction Defined as Recurrent Wheezing or Chronic Cough
B) Physician Diagnosed Wheezing or Chronic Cough.
C) Volume of Outpatient Pulmonary Care including number of pulmonary medications, office and emergency room visits and re-hospitalizations for respiratory illnesses.

Ascertainment of outcomes:

Outcomes will be measured at 4 time points in the first 18-22 months' CA as follows:

1. NICU discharge -baseline interview at to obtain family and environmental history
2. Six months' CA - telephone interview to ascertain incidence of symptomatic airway dysfunction and obtain interval history of need for pulmonary care.
3. Twelve months' CA - telephone interview as at 6 months'
4. 18-22 months' CA- Prior to the NICHD follow-up clinic visit, a telephone interview will be conducted to ascertain incidence of symptomatic airway dysfunction and obtain history of need for pulmonary care.

Anticipated Results
We anticipate that, for infants who develop CLD and those who do not, treatment with a lower vs. higher targeted oxygen saturation range will have less symptomatic airway dysfunction and less need for outpatient pulmonary care in the first 18-22 months' CA. We also anticipate that greater use of CPAP compared with conventional management will be associated with less symptomatic airway dysfunction.

Benefits and Risks
The proposed SUPPORT Follow-on Pulmonary Outcome Study will directly measure symptomatic airway dysfunction and outpatient pulmonary morbidity in infants treated with either a higher vs. lower targeted oxygen saturation. These data will provide important insight into the effect of different levels of supplemental oxygen exposure on airway growth and development in formerly premature infants. In addition to creating a potential model for outpatient pulmonary follow up, the proposed follow on study may improve follow up at the 18-22 month NICHD visit by maintaining contact with families during the interval between NICU discharge and the neurodevelopmental follow up visit. We anticipate no risk to patients enrolled in this observational follow-on study.

B. STATEMENT OF THE PROBLEM

Premature infants have a greater risk for recurrent wheezing, chronic cough and more need for pulmonary care in early childhood than term infants(1-11). Although Chronic Lung Disease (CLD) is a risk factor, the etiology of symptomatic airway dysfunction, defined hereafter as recurrent wheezing and/or chronic cough, in formerly premature infants is not known.

C. HYPOTHESES

The overarching hypothesis is that premature infants exposed to supplemental oxygen and, to a lesser extent, mechanical ventilation, in the neonatal period suffer oxidant stress in the lung in the immediate newborn period that results in impaired airway growth and development. These airway changes predispose premature infants to greater airway dysfunction, respiratory symptoms and need for pulmonary care when challenged with subsequent environmental or infectious exposures.

Specific Hypotheses:

Hypothesis #1- We hypothesize that relative to infants managed with a higher SpO2 range, infants managed with a lower SpO2 range will have less frequent episodes of symptomatic airway dysfunction and reduced need for outpatient pulmonary care at 18-22 months' CA.

Hypothesis #2- We hypothesize that relative to infants managed with prophylactic surfactant and conventional ventilation, infants managed with early CPAP and permissive ventilator strategy will have less frequent episodes of symptomatic airway dysfunction and reduced need for outpatient pulmonary care in the first 18-22 months' CA.

Hypothesis #3- We hypothesize that **among infants with CLD**, infants managed with a lower SpO2 range relative to those managed with a higher SpO2 target range will have less frequent episodes of symptomatic airway dysfunction and reduced need for outpatient pulmonary care during the first 18-22 months' CA.

Hypothesis #4- We hypothesize that **among infants without CLD**, infants managed with early use of CPAP and permissive ventilator strategy relative to infants managed with prophylactic surfactant and conventional ventilation will have less frequent episodes of symptomatic airway dysfunction and reduced need for outpatient pulmonary care during the first 18-22 months' CA.

D. SPECIFIC AIMS

The goal of this project is to understand better the etiology of symptomatic airway dysfunction among formerly premature infants during early childhood by examining the interaction of oxygen exposure (targeted SpO2 range), surfactant therapy and early nasal CPAP in the newborn period.

SA#1 - Measure the effect of lower vs. higher targeted SpO2 on the incidence of symptomatic airway dysfunction and volume of outpatient pulmonary care among infants born $24^{0/7}$ - $27^{6/7}$ weeks' gestation during the first 18-22 months' CA.

SA#2 - Measure the effect of early CPAP and permissive ventilator strategy compared with prophylactic surfactant and traditional ventilator strategy on the incidence of symptomatic airway dysfunction and volume of outpatient pulmonary care among infants born 24-27 weeks' gestation during the first 18-22 months' CA.

SA#3 – Among infants who develop CLD, determine whether CLD is milder in infants managed with low compared with high targeted SpO2 by measuring incidence of symptomatic airway dysfunction and volume of outpatient pulmonary care. A similar analysis will be performed by SUPPORT Trial ventilatory strategy assignment, i.e. early CPAP and permissive ventilation compared with prophylactic surfactant and traditional ventilation.

SA#4 – Among infants who do not develop CLD, determine whether pulmonary outcome is better for infants managed with a low compared with high targeted SpO2 range by measuring incidence of symptomatic airway dysfunction and need for outpatient pulmonary care. A similar analysis will be performed by SUPPORT Trial

ventilatory strategy assignment, i.e. early CPAP and permissive ventilation compared with prophylactic surfactant and traditional ventilation.

E. RATIONALE/JUSTIFICATION

Although synergy in producing airway injury may exist between oxygen toxicity and mechanical forces applied to the lung, animal and human data suggest that exposure to high concentrations of supplemental oxygen alone is sufficient to cause airway narrowing and greater airway dysfunction when exposed to subsequent environmental or infectious challenges. Understanding the relative contributions of oxygen toxicity and mechanical forces on airway growth and development may facilitate development of targeted therapies for preventing or reducing symptomatic airway dysfunction in premature infants.

Why measure symptomatic airway dysfunction and outpatient pulmonary care as an outcome from a clinical NICU interventional trial?

1) Important information will be available on the effect of oxidant gas exposure on airway development and later symptomatic airway dysfunction. Exposure to oxidant gas has been causally linked with later wheezing. Existing data on the relationship between supplemental oxygen therapy and wheezing come from longitudinal cohort studies, a design that suffers from intrinsic limitations that make controlling for potential confounders of respiratory outcome difficult. By randomizing infants to higher vs. lower target saturation ranges, and thereby presumably higher or lower concentrations of inspired oxygen, *the SUPPORT Trial creates a unique, and perhaps the only, opportunity to evaluate the effect of different levels of supplemental oxygen on subsequent symptomatic airway dysfunction and need for outpatient pulmonary care after NICU discharge.*
2) Using clinical measures of outpatient pulmonary morbidity, the effect of NICU based respiratory interventions on respiratory health and need for outpatient medical care can be directly quantified, allowing assessment of whether infants both with and without CLD have improved pulmonary health as a result of the study intervention.
3) The incidence of CLD, defined as an oxygen requirement at 36 weeks' PMA, is an incomplete measure of pulmonary outcome in formerly premature infants during early infancy. CLD as defined above reflects alveolar gas diffusion and NICU oxygen needs. However, outpatient pulmonary morbidity for formerly premature infants is often airway related, involving wheezing either as a primary symptom such as bronchiolitis or as a complicating symptom of lower respiratory tract infection such as pneumonia. The studies proposed here will directly measure the effect of a randomized NICU-based clinical intervention on symptomatic airway dysfunction and outpatient pulmonary morbidity.
4) The risk of a negative trial is reduced. Because the diagnosis of CLD does not completely predict need for outpatient pulmonary care, clinically significant improvements in pulmonary morbidity may occur with minimal or no change in the incidence of CLD. This result has occurred in other interventional trials in which no difference in CLD were observed (12).
5) At present, there is no standard way to measure symptomatic airway dysfunction in premature infants in NICHD pulmonary intervention trials. There is need for a better measure to assess clinical pulmonary outcome to recognize and promote therapies that reduce need for outpatient care of former extremely premature infants.

F. BACKGROUND / PREVIOUS STUDIES

Recurrent Wheezing In Preterm Infants is a Significant Public Health Problem

Outpatient pulmonary morbidity, especially recurrent wheezing and need for outpatient pulmonary care, is an understudied but clinically important outcome measure for former premature infants with and without CLD. Infants born weighing < 1500 grams (very low birth weight, VLBW) and especially infants born weighing < 1000 grams are at increased risk for small airway narrowing, airway hyperreactivity, wheezing, and nighttime cough (1-11). Up to 30-40% of formerly extremely premature infants have episodes of wheezing after NICU discharge with many requiring bronchodilators and frequent health care visits. Up to 40-50% of premature infants require

re-hospitalization, mostly for treatment of respiratory illnesses (9;12;13). In analysis of cross sectional data from the National Maternal Infant Health Survey and 1991 Longitudinal Follow up Survey, the prevalence of asthma-like recurrent wheezing varied markedly with birth weight. Infants with normal birth weight (NBW, > 2500 grams) had a 6.7% prevalence of asthma compared to 10.9% of low birth weight infants (LBW, 1500-2499 grams) and 21.9% for VLBW (14). Mean per capita asthma related costs have been estimated to be 5 times greater for VLBW compared with NBW infants. The net effect is that VLBW infants, who comprise 2% of asthma patients, consume up to 7% of asthma-related therapy costs (14).

Animal Studies

Animal studies suggest that exposure of the premature lung to hyperoxia (without concomitant mechanical ventilation) for relatively brief periods is sufficient to cause airway remodeling and smooth muscle changes that predispose toward airway narrowing and hyperreactivity to subsequent environmental challenges (15-18). In a rhesus monkey model of asthma, Schlegle et al. exposed infant monkeys to repeated cycles of inhaled House Dust Mite Allergen (HDMA), ozone or filtered air. While repeated exposure to either ozone or HDMA had mild effects, exposure to cycles of ozone followed by HDMA resulted in asthma like changes with significant increases in serum IgE, serum histamine, peripheral eosinophilia and greater airway reactivity. Using supplemental oxygen rather than the stronger oxidant ozone, Schulman et al. found that exposure of newborn guinea pigs to 70% oxygen for 96 hours resulted in airway hyperreactivity at 2 and 9 days after the cessation of oxygen. In cell models, intracellular glutathione buffers airway cells against oxidant injury during hyperoxia (19;20). Although the critical period for lung development is comparatively brief in laboratory animals compared with human infants, the duration of hyperoxic exposure (and risk of oxygen toxicity) for treatment of neonatal lung disease may extend for much longer periods in premature infants known to be deficient in anti-oxidant systems such as intracellular glutathione.

Premature Infants <u>With CLD</u> Are At Greatest Risk For Recurrent Wheezing

Among premature infants, infants with bronchopulmonary dysplasia (BPD) are at highest risk for poor pulmonary outcome after NICU discharge. Infants with CLD have small airway compromise with decreased forced expiratory flow velocities, airway hyperreactivity, and increased functional residual volume suggesting airway obstruction (2;5;9;21-24). In a pulmonary follow up of infants with RDS or BPD, De Klein et al. found infants with BPD had reduced FEV1 at baseline while infants with RDS but not BPD had significant improvements in FEV1 following bronchodilator therapy. In this study, a history of recurrent wheezing predicted abnormal pulmonary function (25). In a recent study of infants with CLD, Robin et al. found that 50% of infants with CLD had symptoms of recurrent wheezing and 35% showed significant airway responsiveness to bronchodilators, evidenced by a 24% increase in forced expiratory flow velocity at 75% of expired forced vital capacity (FEF_{75}). This study demonstrated the relationship between recurrent wheezing as a clinical symptom and the physiologic measurement of airway obstruction. Infants with CLD and a history of recurrent wheezing showed greater hyperinflation, expiratory flow limitation and airway responsiveness to albuterol compared to those without a history of recurrent wheezing (24).

Premature Infants <u>Without CLD</u> Have Significant Airway Dysfunction

Among VLBW infants who do not develop CLD, several studies of pulmonary outcome have found an association between neonatal oxygen exposure and increased prevalence of expiratory flow dysfunction and airway hyperreactivity (4;11;26-29). Some authors attribute reductions in airway function to intrinsically small airways as a consequence of poor intrauterine growth rather than superimposed airway injury or reactivity from neonatal respiratory disease (1;30). However, because small airways alone do not fully explain airway hyperreactivity, other mechanisms of small airway dysfunction are necessary to explain respiratory symptoms.

Several pulmonary outcome studies have reported significant increases (2-fold or more) in airway obstruction among VLBW infants without CLD following exposure to as little as 40% oxygen for 5 days (3;4;8;26). Not all studies have had similar results suggesting variability in effect or susceptibility of babies to oxygen exposure (31;32). In 1982, Coates et al. described increased small airway resistance at 10 year follow up of mildly

premature infants (mean gestational age 31 weeks and birth weight 2000 grams) treated with a high oxygen (O2) regimen and those exposed to a low O2 regimen for the treatment of respiratory distress syndrome (RDS). Mechanical ventilation was not used in either group. Pulmonary function tests were performed on survivors receiving either the low or high supplemental oxygen regimen ten years after their initial illness. Infants treated with high levels of supplemental oxygen alone (no mechanical ventilation) had decrements in airway function similar to decrements in function reported for a historical cohort of RDS survivors treated with ventilation and high levels of supplemental oxygen. From these data, the authors concluded that neonatal exposure to high oxygen concentrations in the absence of mechanical ventilation is capable of causing long-term change in small airways (28). These studies suggest that use of lower supplemental oxygen concentration may improve respiratory health of infants who do not develop CLD.

Premature Infants Without CLD Have Increased Risk of Symptomatic Airway Dysfunction and Need for Outpatient Pulmonary Care.

For VLBW infants without CLD, the prevalence of parental or physician reported wheezing is increased compared with term infants, with estimates of the prevalence of wheezing ranging from 10-38% (4;8). Prevalence of wheezing requiring medications is greater compared with term infants. VLBW infants have a 2-4-fold increase in respiratory related re-hospitalization rates compared with term infants (4;8;33-35). Although most studies have found the risk of recurrent wheezing remains elevated throughout childhood, an Australian longitudinal follow-up cohort of VLBW infants found the prevalence of wheezing remained elevated for 2 years then returned to baseline (32;36).

Prevalence of Symptomatic Airway Dysfunction in Formerly Preterm Infants During the Surfactant Era Remains High

With the advent of surfactant therapy, survival of small infants increased dramatically and the incidence of CLD changed minimally (37-40). Classic BPD evolved into the "new CLD" characterized by reduced alveolarization and more variable airway changes (41). Pulmonary follow up studies during the surfactant era showed reduced pulmonary morbidity in surfactant treated patients. Typical of these studies, Sell et al. found the incidence of asthma was significantly lower in infants given synthetic surfactant compared with those given air placebo. Pelkonen et al. performed PFT measurements on 40 children aged 7-12 years who were born before 30 weeks of gestation with an immature surfactant system, and were randomized to one of three treatment groups: prophylactic surfactant, rescue surfactant and placebo (air). Spirometric parameters of preterm born children were compared with those of 20 children born at term. Bronchial obstruction was found in 53% of the prophylactically treated group, in 36% of the rescue group, in 67% of the placebo group, and in 0% of the control group (42). A recent report suggests that the introduction of surfactant therapy markedly altered the pulmonary outcome of premature infants. Published in 2001, the Newborn Lung Function Project Group reported results of a prospective 12-year follow-up of VLBW infants following the introduction of surfactant therapy (5;8;43). Among infants with CLD, wheezing symptoms decreased from 50 to 16% from the period before compared with the period after surfactant therapy became available. However, among infants without CLD the prevalence of wheezing increased from 14% to 38% with the introduction of surfactant. These data suggest that surfactant therapy has an effect on outpatient respiratory health and underscores the need to consider outpatient pulmonary outcomes in evaluating therapeutic strategies that potentially decrease surfactant replacement therapy.

CLD is an Incomplete Predictor of Outpatient Pulmonary Morbidity

Several authors have looked to respiratory symptoms and need for outpatient pulmonary care as outcome measures for neonatal lung disease (9;10;12;24). In 1988, from a retrospective chart review of 605 premature infants < 1500 grams, Shennan et al. found that the presence of BPD (oxygen requirement at 36 weeks PMA) had a 63% positive predictive value and a 90% negative predictive value for abnormal pulmonary outcome in the first 2 years of age. However, this study from before the era of exogenous surfactant therapy defined abnormal pulmonary outcome as death, oxygen requirement at 40 weeks PMA, 2 or more respiratory related hospital admissions, wheezing requiring drug therapy or persistent wheezing resulting in growth failure, handicap or hypotonia at 1 year of age. Such restrictive criteria for abnormal pulmonary outcome are likely to

underestimate the burden of recurrent wheezing on former premature infants and their families. Several recent interventional studies show that CLD is an incomplete predictor of clinical wheezing and need for outpatient pulmonary care and suggest that differences in oxygen exposure or oxidant stress may affect pulmonary outcome without affecting the incidence of CLD.

Interventional Trials That Did Not Reduce CLD But Did Reduce Outpatient Pulmonary Morbidity.

Recent data in preterm infants treated with human recombinant superoxide dismutase (SOD) found that anti-oxidant therapy did not reduce the incidence of CLD. However, among infants < 27 weeks gestation SOD therapy resulted in significant reductions in the first year after NICU discharge in the number of emergency room visits and number of re-hospitalizations for respiratory problems and reductions in the need for bronchodilators suggesting a reduced prevalence of wheezing in patients treated with SOD (12). In a randomized, multi-center trial from Helsinki, N acetyl cysteine did not reduce the incidence of CLD. Outpatient pulmonary outcome of these patients has not been reported.

Treatment of Premature Infants With Higher Targeted Oxygen Saturations Is Associated with Poorer Pulmonary Outcome

In the STOP-ROP Study, infants exposed to higher levels of oxygen to achieve a targeted saturation of 96-99% compared with 89-94% had greater risk of adverse pulmonary events including pneumonia, chronic lung disease exacerbations and need for diuretics, oxygen and hospitalization at 3 months" corrected age. *Although all infants in this study had CLD at enrollment, different targeted oxygen saturation were associated with large differences in pulmonary morbidity.* Adverse pulmonary outcomes occurred with differences in FIO2 of as little as 10% for patients treated with ventilation, CPAP or hood (36% $\pm$ 14% vs. 46% $\pm$ 20%, respectively for low vs. high saturation range) and 5% for infants treated with nasal cannula, (26% $\pm$ 6% vs. 31% $\pm$ 11%, respectively for low vs. high saturation range) (44). In a similar study, The Benefits of Oxygen Saturation Targeting (BOOST) Trial randomized infants < 30 weeks' gestation to higher (95-98%) or lower (91-94%) saturations ranges beginning at 32 weeks' PMA to determine whether infants managed with higher targeted saturation range showed better growth and neurodevelopment. As in the STOP-ROP study, need for oxygen therapy was prolonged. Trends towards an increased risk of pulmonary death and fewer outpatient office visits (median 27.5 vs. 31.3, $p < .11$) were seen in the lower targeted oxygen saturation group (13).

Factors In Addition To Prematurity and Oxygen Contribute To Symptomatic Airway Dysfunction

Multiple factors in addition to prematurity and oxygen contribute to the development of airway dysfunction in children (Table 1). In the SUPPORT TRIAL Pulmonary Outcomes Follow on Study, these potential covariates will be measured and controlled for using a randomized trial design. These covariates will be also be evaluated as independent predictors of pulmonary outcome in multivariate analyses.

Table 1. ***Important Covariates in Etiology of Recurrent Wheezing***

Demographcis – race, sex, ethnicity, parental factors (educational level, poverty status, and age), and family history of wheezing or atopy.

Environmental – urban vs. rural residence, presence of dust, tobacco smoke or wood smoke in the home, pets

Health Services – adherence to medications, availability of level of health care

Medical- gastroesophageal reflux, congenital anatomic airway abnormalities, RSV and other viral infections

G. METHOD/ PROCEDURES

NICHD SUPPORT Trial Follow-on Study of Pulmonary Outcomes

G.1 Description of study design

This study will add an 18-22 month longitudinal, prospective follow-on study of surviving infants enrolled, randomized and treated as part of the multi-center NICHD Neonatal Research Network SUPPORT Trial.

G.2 Definition of study population

Infants with gestational age of $24^{0/7}$-$27^{6/7}$ weeks' gestation by best obstetrical estimate.

Inclusion criteria:

- Full resuscitation as necessary, i.e., no parental request or physician decision to forego resuscitation
- Parents/legal guardians have provided consent for enrollment
- No known major congenital malformations
- Survival to hospital discharge

Exclusion criteria

- Transport to the center after delivery
- Research apparatus/study personnel are not available.

G.3 Description of study intervention

Before delivery, infants will be randomized to subsequent management with high vs. low target oxygen saturation according to the SUPPORT Protocol. The SUPPORT Follow-on Study of Pulmonary Outcomes begins just prior to NICU discharge (Figure 1).

Figure 1. **SUPPORT Trial Follow-on Study**

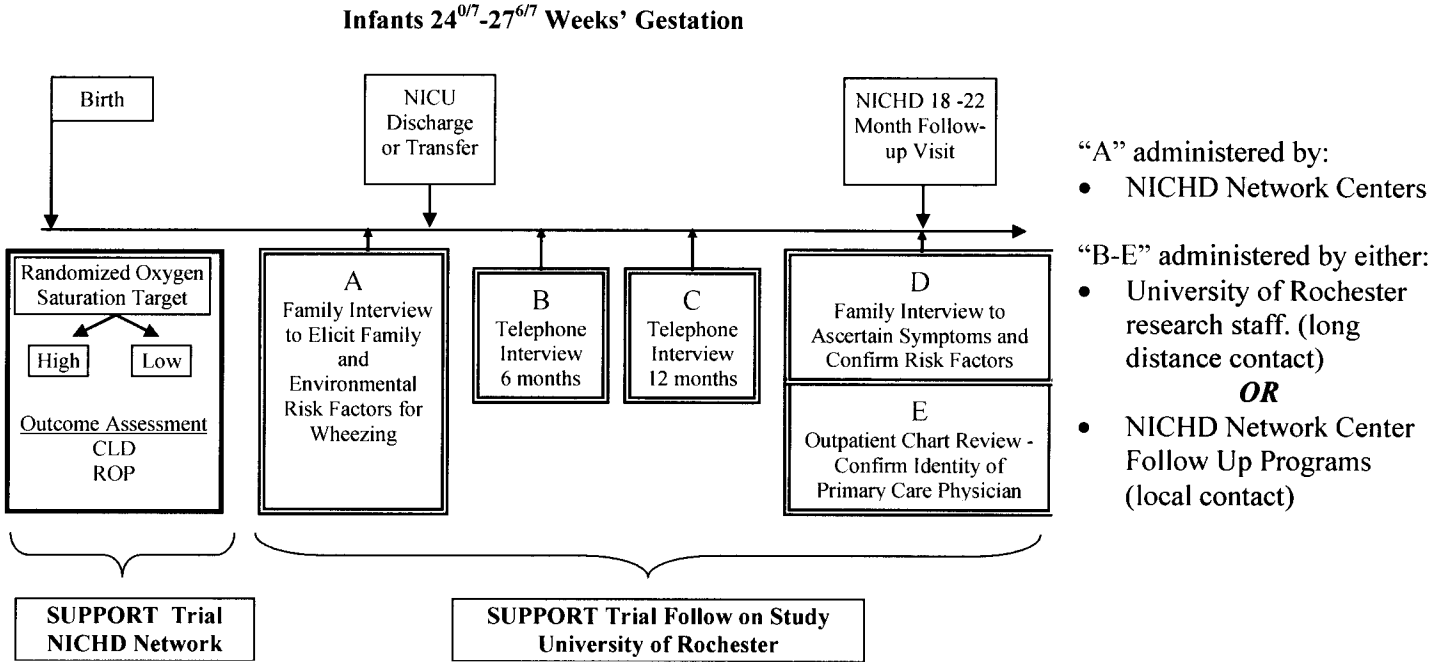

Fig 1, A. Parent (Guardian) Interview to Elicit Family and Environmental Risk Factors for Wheezing and Cough
The family interview will be administered at each participating Network Center by site study nurses

prior to NICU discharge or transfer. The questions are based on intake questions used by the Tucson Respiratory Study and are designed to elicit family history of asthma, atopy, and home environment and to identify likely care givers (Questionnaire, Appendix A). Consent for release of medical information will be obtained to facilitate contacting physician offices to obtain office data.

Fig 1, B. Telephone Interview at 6 months PMA – respiratory interval history

Fig 1, C. Telephone Interview at 12 months PMA – respiratory interval history

Telephone interviews will be undertaken at 6 and 12 months to obtain limited interval history of respiratory problems including wheezing, cough, medications used, and health services sought for respiratory related problems (Questionnaire, Appendix B).

Fig 1, D. Parental Interview to Ascertain Incidence of Wheezing and Cough and Confirm Risk Factors- This parent interview will also be administered by telephone, prior to the regularly scheduled 18-22 month NICHD developmental follow up clinic visit. Contacting parents prior to the office visit will help improve the Developmental Follow Up Clinic attendance rate and will allow the clinic visit to provide a back up means to contact the family. Telephone interviews, the 2 limited telephone interviews and the second family history interview at 18-22 months, will be conducted either by the local NICHD Follow Up Program or long distance from Rochester, based on center preference (see table 2 below). The interview questionnaires are based on questionnaires administered by the Tucson Respiratory Study at approximately one year of age (Questionnaire, Appendix C). Questions are designed to ascertain the frequency and severity of wheezing and cough episodes. In addition, risk factors obtained at the 1st interview will be confirmed.

In an effort to help standardize the interview, a training program will be provided to train local interviewers on a standard approach to administering the questionnaires.

Fig 1, E. Outpatient Chart Review - Confirm Identity of Primary Care Physician

To confirm results of physician report of wheezing obtained by telephone interview, patients undergoing telephone interview will have their primary care physician's medical record reviewed.

E.1 – Physician report of recurrent wheezing and chronic cough

E.2 – Frequency of outpatient pulmonary care. The volume of outpatient pulmonary care including, outpatient primary care physician office visits, pulmonary specialty care, emergency room visits, hospitalizations and the number and duration of pulmonary medications will be obtained from primary care physician chart review mailed from and returned to each local Center. To incentivize primary care office staff to complete the chart review, a $25 honorarium will be offered for successful completion of the chart review form (45-47).

G.4 Precise definition of co primary/secondary outcomes

G.4.1 Definition of primary outcomes- parental report of recurrent wheezing and chronic cough.

Two primary outcomes will be measured, the incidence of recurrent wheezing and incidence of chronic cough. Whether individual symptoms (recurrent wheezing or chronic cough, alone) or a combination of these symptoms (wheezing and/or chronic cough, together) best quantifies symptomatic airway dysfunction following premature birth is controversial. Many studies have used wheezing alone as a primary outcome measuring pulmonary morbidity in formerly premature infants (10;12;14;48). In 1996, Greenough, using a combined outcome of either wheezing or chronic cough as a measure of symptomatic airway dysfunction, found that greater pulmonary symptoms were associated with longer durations of supplemental oxygen and mechanical ventilation (49;50). Later, in a follow-up study of infants enrolled, The United Kingdom Oscillator Study (UKOS), Greenough found that frequent wheezing episodes but not chronic cough were associated with neonatal respiratory events (51;52). In our study, to address this issue most conservatively, recurrent wheezing and chronic cough will be measured as co-primary outcomes. Secondary analyses will consider these outcomes in combination.

The incidence of wheezing will be ascertained using the primary question used and validated in the Tucson Children's Respiratory Study (a large prospective birth cohort study of term infants) (53-59), "Has his/her chest ever sounded wheezy or whistling?" (53). Likewise, the incidence of cough will be ascertained using the Tucson question, "Has this child ever had a cough when he/she did not have a cold?" (53). As in Greenough's study, recurrent wheezing will be defined as episodes of wheezing occurring more than twice/week. Chronic cough will be defined similarly, cough occurring as more than twice/week. Additional questions will further characterize the wheezing and coughing episodes, including whether symptoms were associated with a viral illness (parental report of a "cold") or an environmental exposure. A symptom diary will be offered to study participants to help facilitate recall of pulmonary symptoms and need for outpatient pulmonary care.

To facilitate The Tucson Children's Respiratory Study administered the questionnaires both in person and by phone, depending on patient availability. The investigators did not undertake a formal validation of phone vs. face-to-face administration of the questionnaire. Anecdotally, based on phone conversation with the study coordinator, investigators did not observe a difference in quality of responses between phone and questionnaires administered in person.

G.4.1.1 Standard Definition of Wheezing

Several studies have found that multiple colloquialisms in both English and Spanish can be used to describe wheezing (60-64), creating opportunity for misinterpretation of respiratory sounds and potential for over or under estimation of the incidence of wheezing. Other studies have found that clips of respiratory sounds played for families improve accuracy of symptom reporting (65;66), providing data relatively free from biases due to language, culture, literacy or interviewing techniques. To minimize variation in interpretation of respiratory sounds as wheezing we will provide a verbal AND a brief audio clip that can be played for the interviewee at the beginning of the interview (electronic Appendix D). Accompanying the audio clip, wheezing will be defined verbally by the interviewer as an expiratory sound (a sound that is made when breathing out, not in) coming from the chest, sometimes described as whistling or musical. Although not yet widely used, use of audio clips to standard symptom definition is the best approach to bridge the language gap that exists between English and Spanish and among Spanish speaking populations using different dialects or colloquialisms.

In administering the questionnaires, every effort will be made to accurately measure the occurrence of pulmonary symptoms and health care and medication use, thus establishing the true incidence of pulmonary morbidity in the study population as a whole. Most importantly, however, because pulmonary morbidity is a blinded outcome measure from a randomized controlled trial, bias favoring one study arm over another should not occur.

G.4.1.2 Parental Report for Non-English Speaking Populations

Upon finalization of the questionnaires, Spanish language versions will be created and made available to all centers. The Cornell Translation Service, a University based professional translation service, will be contracted to perform the translation. For centers choosing Rochester to administer the questionnaire to their patients, English and Spanish speaking individuals, trained to administer the questionnaires, will conduct the telephone interviews. For centers choosing to administer the questionnaires locally, each center will be free to choose their primary interviewer who has the necessary skills. Administration of the questionnaire by a native speaker of the local Spanish dialect is recommended. An audio clip and verbal definition of wheezing will be presented to the respondent to standardize interpretation of wheezing and to minimize ascertainment biases due to language, culture, literacy or interviewing techniques.

G.4.1.3 Parental Report of Pulmonary Symptoms Is a Reliable Outcome Measure of Airway Dysfunction

Evaluation of frequency and severity of respiratory symptoms by parental questionnaire and need for pulmonary care has been used as the primary outcome in multiple follow up studies of term and premature infants (10;12;14;48). A recent review evaluated the value of respiratory symptom history ascertained by parental questionnaire in determining the risk for developing asthma in early childhood. By evaluating 9 large, longitudinal, full term birth cohort studies and reviewing the original questionnaire from 7 of these studies, Koopman found that the questions posed to parents eliciting a history of wheezing in their infants were similar. Parental report of wheezing predicted an increased risk for later respiratory symptoms, including asthma. In the studies proposed here, incidence of recurrent wheezing and chronic cough ascertained by parental report will be primary outcomes, rather than physiologic measurements of airway dysfunction, for several reasons.

G.4.1.4 Reasons to Use Parental Report of Recurrent Wheezing and Chronic Cough as Primary Outcomes

- Parental interview can be performed more readily on large numbers of patients. The validity of this approach has been shown in several longitudinal studies including The Tucson Respiratory Study.
- Recurrent wheezing is highly correlated with changes on pulmonary function testing (PFT). In infants with CLD, a history of wheezing was associated with greater expiratory flow limitation, hyperinflation and airway responsiveness to albuterol on PFT compared to those without such a history (24).
- Parental recall of respiratory illnesses has been shown to correlate strongly with review of medical office records. For asthma and bronchitis in the past year, Pless et al. found good agreement between recall of 288 parents and physician office chart review. Parental education and occupation were not predictive of a parent's ability to recall the illness (67). In an assessment of parental recall done to evaluate minor injury in children, Harel found recall declined with time, with the best recall occurring in the first 3 months after injury with further decline after 6 months from the time of the injury (47;68;69).
- Symptomatic airway dysfunction can be assessed in a standardized way. The NHLBI Consensus Expert report developed standardized questions to assess severity of airway dysfunction. Three standardized questions from this report will be administered at 6, 12 and 18 months to assess symptom severity (70).

G.4.2 Definition Of Physician Diagnosed Symptomatic Airway Dysfunction. Secondary outcomes will include physician report of recurrent wheezing, defined as more than 1 episode of wheezing at an office visit, or chronic cough, defined as cough not associated with a cold at more than one office visit (49;50). Physician diagnosed airway dysfunction will be collected by parental report during the telephone interviews and by review of the primary care physician's medical chart.

G.4.3 Definitions of Secondary Outcomes - Measures of Volume of Outpatient Pulmonary Care

Important secondary outcomes of outpatient pulmonary morbidity will be collected (Table 3).

Table 3. *Secondary Outcomes, Covariates and Sources*	
Outcomes	Source
Secondary Outcomes	
Number and duration of outpatient pulmonary medications including bronchodilator, diuretic, methylxanthine, and inhaled and systemic steroid therapy.	Family interview, primary care chart review
Number of office visits for respiratory illnesses including pneumonia, bronchiolitis, asthma, bronchitis	Family interview, primary care chart review
Number of emergency room visits for respiratory illnesses including pneumonia, bronchiolitis, asthma, bronchitis	Family interview, primary care chart review
Number of re-hospitalizations for respiratory illnesses including pneumonia, bronchiolitis, asthma, bronchitis	Family interview, primary care chart review
Growth at 18 months PMA (height, weight and head circumference)	NICHD follow up clinic data

G.4.4 Data Collection

G.4.4.1 Data Collection: Ascertainment of Outcomes - Field Work

A. Ascertainment of Wheezing and Outpatient Pulmonary Morbidity By Telephone Interview. There will be 4 parental interviews over 18-22 months, one prior to NICU discharge and 3 subsequent telephone interviews at 6 month intervals to collect data on recurrent wheezing, chronic cough and volume of outpatient pulmonary care (Figure 1, A-D above). Based on review of longitudinal studies of full term infants in which follow up patient contacts occurred quarterly to once every 18 months', a 6 month interval for follow up patient contacts is planned in an effort to reduce parental recall omissions which are more likely to occur with less frequent follow up (48;68). The 4 interviews are designed to collect the primary and secondary outcomes of the follow-on study. Other inpatient and outpatient data will be collected as part of the NICHD Neonatal Research Network Generic Database (GDB) and Follow-up Program.

B. Interview Instruments – (Appendices A-C) Questionnaires are based on the Tucson Children's Respiratory Study, a longitudinal cohort study that followed healthy term infants from birth to over 20 years of age. Questionnaires have been updated with validated symptom severity and tobacco smoke exposure questions, a current list of available respiratory medications and modifications that address health issues faced by formerly premature infants such as use of palivizumab for RSV prophylaxis. The original Tucson questionnaires are designed to elicit a thorough history of possible covariates, such as environmental and infectious exposures and family histories of atopy, asthma or respiratory disease.

C. Administration of Interview Instruments – Telephone interviews will be initiated in one of two ways (table 2):

C.1 University of Rochester research staff (long distance contact)

The University of Rochester Neonatology Research Group has conducted similar telephone interview designs as part of an ophthalmologic outcome study of patients enrolled in a randomized trial of cryotherapy to treat ROP and a 15-year, longitudinal neurological assessment conducted by telephone survey among 132 infants treated with surfactant. Telephone follow up rates were 96% follow up at 7 years and 95% follow up at 15 years (71). In the study proposed here, the University of Rochester Health Services Research Group (HSR Group), will conduct the telephone interviews.

In telephone follow up surveys conducted by the HSR Group, follow up rates at 12 months' have exceed 75% in populations at high risk for being lost to follow up (72-78). Working with NICHD Network Centers to assist in tracking local families, follow up rates for this Follow-On Study are expected to exceed 80% and should approach the average annual NICHD follow up rate of 83%.

To facilitate tracking and record keeping, Network Centers choosing Rochester to administer questionnaires to their patients (table 2) will provide contract information to the Rochester site. Research Triangle Institute will provide monthly updates of patients due for interviews. Local centers will be responsible to maintain updated contact information. Each interview will close with a question as to whether the family plans a new address or phone number prior to the next interview. The names and phone number of a friend or relative and their primary care physician will be sought so that they may be contacted in the event that contact with the patient is lost. If contact information is updated, the new contact information will be transmitted back to the local center. By interviewing families every 6 months', a higher follow up rate will be achieved because family contact information will not become so out of date that the family is lost or that re-contacting them is inefficient. We anticipate that each

interview will require 2 hours of staff time, with 20-30 minutes to conduct the interview and 90 minutes to contact family and enter data.

Advantages of Conducting Telephone Interviews From a Central Research Facility

Conducting the telephone interviews from Rochester will:
1) require less effort from the individual Network Centers
2) allow standardization of the telephone interview by a core group of trained interviewers
3) blind the telephone interviewer to the SUPPORT Trial study group designation
4) reduce the cost of the study by consolidating the telephone training and follow up at one site.

C.2 NICHD Network Center Follow Up Programs (local contact, Table 2)

Individual NICHD Network Centers may choose to undertake administration and tracking of patients enrolled in the SUPPORT Follow-On Study. Local administration of the telephone questionnaires capitalizes on existing NICHD resources available at local centers. Each Network Center choosing local administration of the telephone questionnaire will identify one or more telephone interviewers who will undergo training in the administration of the questionnaire and tracking of the enrolled patient. The Rochester Health Service Research Group will serve as a resource to answer questions regarding administration of the questionnaire.

Advantages of Conducting Telephone Interviews From the Local Network Centers

Conducting the telephone interviews from Local Centers will:
1) reduce risk for HIPPA violation
2) capitalize on existing rapport between the patient's family and their local center
3) avoid redundancy in making tracking calls to families

D. Physician Office Record Assessment of Wheezing, Cough and Outpatient Pulmonary Morbidity

Physician office charts will be reviewed to determine physical findings of wheezing, cough, medication use and respiratory-related hospitalizations. Consent to release medical information will be obtained at the time of study consent. As part of the 18-22 month telephone questionnaire, office contact information will be obtained from the family. For primary care pediatricians, a copy of the family's signed consent authorizing release of medical information and an office data extraction form will be mailed or faxed to the provider. The form will be based on a similar document used by the Rochester Research Group to obtain medical information on respiratory health issues. To incentivize office staff to complete the data extraction form, a $25 honorarium will be offered upon receipt of the completed form.

G.4.4.2 Data Collection: Ascertainment of Environmental and Genetic Covariates

Ascertainment of important environmental exposures and genetic risk factors that might confound the relationship between supplemental oxygen exposure and symptomatic airway dysfunction will be obtained along with the primary outcomes during the same telephone and family interviews. Tobacco smoke exposure is a potentially significant risk factor for airway dysfunction. The tobacco smoke question in the Tucson Study has been replaced by a question shown by Dr. Wakefield et al to correlate with cotinine levels in infants (79;80).

Table 4. Postnatal and Genetic Covariates Evaluated as Potential Confounders of Oxygen and Wheezing

Covariates in Home Environment and Exposures The initial questionnaire and 6 month interviews will gather information on other *inhaled exposures* (tobacco, wood stoves, cold air), *residence* (urban vs. rural residence), *infectious exposures* (RSV, palivizumab) and medical risk factors (gastroesophageal reflux, congenital anatomic airway abnormalities)

Covariates in Family History Questionnaires will elicit *family history* of atopy (family history of asthma, eczema or allergy to foods, pets, molds, pollen or dust).

G.4.4.3 Data Collection: Ascertainment of Primary Exposure

Oxygen Exposure

In the SUPPORT Trial, it is assumed that managing infants with a higher vs. lower targeted oxygen saturation range will result in different levels of supplemental oxygen exposure. The SUPPORT Trial will collect data on FIO2 exposure to quantify the anticipated difference. As part of the SUPPORT Trial, FIO2 values will be recorded and analyzed at many time points including time of admission, first blood gas, and as described in the SUPPORT Manual of Operations, Chapter 10 Safety Monitoring Form. Because oxygen is the primary exposure in the SUPPORT Follow-on Study and plays a central role in the disease model proposed, oxygen exposure will be quantified as described in the main SUPPORT trial and analyzed as a predictor of later symptomatic airway dysfunction.

G.5 Sample size estimate with some statistical support based upon primary outcome

G.5.1 Sample Size

The SUPPORT Trial anticipates enrollment of 1310 patients $\geq 24^{0/7}$ and $\leq 27^{6/7}$ weeks' gestation, providing 80% power to detect a 10% difference between treatment groups in the incidence of death/CLD and death/stage III Retinopathy of Prematurity (ROP). Assuming mortality of 22% for infants in this GA range (NICHD 2001-2002 data), 1021 infants would be expected to survive and be eligible for the SUPPORT follow-on study.

Power for detecting a difference between the high vs. low saturation groups for the primary outcome

First we consider power for detecting a difference between the high and low saturation groups for the first primary outcome, recurrent wheezing. We expect the incidence of wheezing to be about 0.17 in the low saturation group and about 0.31 in the high saturation group (12). For the power calculations, we also consider a scenario with a smaller difference between groups: 0.19 for the low saturation group and 0.29 for the high saturation group. We expect the follow up rate to be about 80% (NICHD historical average follow up rate), which would result in data on about 816 patients. We also consider a lower follow up rate of 65%, which would result in about 663 patients. Power to detect a difference between groups based on a chi-square test with type I error alpha set at 0.05 is given in Table 5 for each scenario. From those results, we expect to have more than 80% power for the primary outcome. Also of interest are subgroup analyses, where we look separately at the CLD and non-CLD subjects. Of survivors, we expect 37% or 378 infants to have CLD. For the CLD group, we expect the incidence of wheezing to be about 0.5 in the high saturation group and 0.3 in the low saturation group. If there is a 80% follow up rate, we will have 95% power to detect a difference between the two groups. For the non-CLD subgroup, we expect the incidence to be 0.2 and 0.1 in the high and low groups, respectively. With 80% follow up, we will have 92% power. Thus, we expect to have adequate power for the primary outcome even in the analyses stratified by CLD.

Table 5. Power for primary outcome.

Follow-up rate	Low Saturation	High Saturation	power
80%	0.17	0.31	0.99
80%	0.19	0.29	0.90
65%	0.17	0.31	0.98
65%	0.19	0.29	0.83

Power for detecting a difference between the high vs. low saturation groups for secondary outcomes

We expect the study to be adequately powered for analysis of important secondary outcomes such as use of pulmonary medications. Based on results reported in Davis et al. for infants less than 27 weeks' gestational age [22], we expect the rate of pulmonary medication use to be 0.42 in the high saturation group and 0.19 in the lower saturation group. In that case, even with a 65% follow up rate, we would have more than 99% power to detect a difference between the groups with a chi-square test. Similarly, the CLD subgroup analyses would have more than 80% power under those assumptions. Based on the power numbers above, we could potentially enroll fewer subjects in the trial and still have adequate power. However, we choose to over enroll slightly to make up for the fact that some patients will likely be lost to follow up. The recruitment time will be that of the SUPPORT Trial (2 years) with a run out period of 18-22 months to ascertain follow-up outcomes. The total study period is 36-40 months.

G.5.2 Data Analysis

Analysis of primary dichotomous outcomes will be performed by chi square test and presented as a relative risk for development of that outcome. Number of outpatient pulmonary visits for respiratory illnesses will be presented as median values. The Wilcoxon Rank Sum test, a non-parametric alternative to the two-sample t-test, will be used to test for differences between the two groups. Statistical analyses will need to consider the effect of multiple comparison groups on the level of statistical significance. All analyses will be performed in conjunction with the Research Triangle Institute (RTI, North Carolina), the biostatistical support group for the NICHD Neonatal Network. Data will be presented as shown in tables 5-6. Mean FIO2 values in the high and low SpO2 groups will be compared by two sample t-test. Secondary analyses will be done to evaluate the effect of ventilator strategy on pulmonary outcome and presented similarly to table 5 and 6.

Table 6. *Primary Dichotomous Outcomes*	**Low Saturation**	**High Saturation**	**RR**	**CI**	**p-value**
Parental Report of Recurrent Wheezing (%)					
Physician Diagnosed Recurrent Wheezing (%)					
Need for Outpatient Pulmonary Medications (%)					
Need for Physician Visit for Respiratory Illness (%)					
Need for Re-hospitalization for Respiratory Illness (%)					

Table 7. *Primary Outcomes – Continuous Outcomes*	**Low Saturation**	**High Saturation**	**p-value**
Number of Physician Visit for Respiratory Illness (Median)			
Number of Emergency Visits for Respiratory Illness (Median)			
Number of Re-hospitalization for Respiratory Illness (Median)			

G.5.2 Expected Results

We predict that premature infants managed with a lower targeted oxygen saturation range compared to those managed with a higher targeted oxygen saturation are exposed to lower levels of supplemental oxygen and have reduced risk of recurrent wheezing in the first 18-22 months' CA.

G.5.2 Anticipated Problems and Solutions

1) Participant attrition. As seen in the sample size calculation, the potential for patients to be lost to follow up over time will be offset by over enrolling patients to participate in the follow up. Because patients who enroll in the SUPPORT Trial are randomized, there should be no systematic bias favoring one group over another among patients who are lost to follow up. However, if loss to follow up is in part caused by the treatment or outcomes, this could bias the results. We will therefore investigate whether there are differences in key variables for subjects who are lost to follow up compared to those who remain in the study. For example, we will test whether subjects in one treatment arm were more likely to be lost to follow up than in the other arm. Similarly, we will compare wheezing rates at 6 months' for those who are later lost to follow up compared to those who remain in the study. We do not expect to see any major differences.
2) Difficulty tracking families. With mobile families, keeping contact information up to date may be difficult. To promote successful follow up in both the Pulmonary Outcome Study described here and the routine NICHD neurodevelopmental follow up visit at 18 - 22 months, each center will be responsible to track families to maintain current contact information for both the family and primary care physician.
3) Center variability in administering the questionnaire. With 11 centers administering the telephone questionnaires, variation in techniques and styles in administering the questionnaires has the potential to introduce ascertainment bias. To minimize this risk, a face-to-face training program will be conducted by he Rochester Site for all staff administering the questionnaires.
4) The SUPPORT Follow-on Study of Pulmonary Outcomes has been prepared as the central project for Dr. Stevens' Patient Oriented Clinical Research Grant (K23 Award), revised submission 7/1/05. If approved, funds from the K23 will be available to offset a portion of the cost of conducting this

SUPPORT Trial Follow-on study. If not approved, NICHD funding has been approved to support this project.

5) Initiation of the Pulmonary Outcome follow On Study after enrollment into SPPORT has begun.

5.1 Babies already enrolled in SUPPORT

To help assure pulmonary outcome assessment for all SUPPORT patients, families of babies already enrolled in SUPPORT will be approached with a separate consent to enroll in the Pulmonary Outcome Study. IRB approval of this consent form will be required.

5.2 *Future babies eligible for enrollment in SUPPORT*

Going forward, a modified SUPPORT Consent Form, which includes consent for the Pulmonary Outcome Study, will be need to be prepared at each center. The revised SUPPORT Consent will require

G.6 Available population/compatibility with other ongoing protocols

Another secondary study proposed by a group independent from ours is looking at the genetics of reactive airways disease in patients enrolled in the SUPPORT Trial. The follow on study proposed here should be complementary to the genetics study, enhancing the both the quality and quantity of data on the prevalence of wheezing and need for outpatient pulmonary care in patients enrolled in the SUPPORT Trial.

G.7 Estimate of projected recruitment time

The recruitment time will be that of the SUPPORT Trial with a 18-22 month period of follow up to ascertain primary and secondary outcomes.

H. RISKS / BENEFITS, WITH ESTIMATE OF FREQUENCY / SEVERITY OF RISKS.

By using clinical measures of outpatient pulmonary morbidity, the effect of NICU based respiratory interventions on respiratory health and need for outpatient medical care may be quantified, allowing assessment of whether infants who develop CLD and those who do not have improved pulmonary health as a result of the study intervention. In addition to creating a potential model for outpatient pulmonary follow up, the proposed follow on study may improve follow up at the 18-22 month NICHD visit by maintaining contact with families during the interval between NICU discharge and the follow up visit. We anticipate no risk to the patient of this observational follow on study.
